ACCORDING to the *Neue Preussische Zeitung* the loss of young male life has been so large that parents of girls in Germany are looking out for careers that will render them independent of marriage. The number of women who desire to become teachers is in excess of requirements, and in Prussia alone there are about 4,000 women medical students. Schools have been established for training girls to be librarians, sick nurses, and children's nurses.

DR. CHARLES S. MYERS, F.R.S., Lieut.-Colonel R.A.M.C., Director of the Psychological Laboratory, Cambridge, will give the second of two lectures on present-day applications of experimental psychology at the Royal Institution of Great Britain, on April 18th, at 3 p.m. The first lecture dealt mainly with the results which experimental psychology has yielded, and may be expected to yield, in the selection of individuals for work requiring special skill, in the prevention of industrial fatigue, and in the application of scientific management to industrial conditions. The principal subject of the second lecture will be the application of the teachings of modern psychology to the proper understanding and treatment of cases of nervous breakdown.

DR. EMILE ROUX recently reported that of the staff of the Pasteur Institute, normally numbering 200, 126 were mobilized in August, 1914. Of these 41 were medical men, 3 chemists, 6 veterinarians, and 76 officers and soldiers. Most of the laboratories had to be closed, only those for rabies, diagnosis, cholera and typhoid vaccination, animal vaccines, and serumtherapy continuing at work. Notwithstanding this curtailment of its activities the institute has rendered enormous services to the armies. Every French army is provided with a laboratory of its own on a large scale and a hospital for contagious diseases. There are more than two hundred laboratories worked by the institute. It has supplied to the army more than nine million doses of antityphoid vaccine. It also furnished the Serbian army with vaccine. Special services were established for malaria and dysentery. At the beginning of the war only 150,000 doses of antitetanus serum were available; within a few months the amount was increased to four million doses. At the beginning the black troops were decimated by pneumonia, and the institute prepared a vaccine which stopped the epidemic.

LIEUT.-COLONEL G. A. CASALIS DE PURY, S.A.M.C. (*Paris méd.*, 1918, viii, No. 3), contributes an interesting note on the medical history of the Basutos which, besides telling the old story of the evil effects of the first contact of natives with the so-called civilization of adventurous Europeans, brings out the sequence of syphilis and malignant disease on a virgin soil. In 1830 his grandfather settled among the Basutos as a missionary, on Livingstone's advice, and was followed there by his son and grandson (Lieut.-Colonel de Pury) as medical men. Until the Kimberley diamond fields were opened up the Basutos lived a happy, healthy, patriarchal life, without prostitution or syphilis, and entirely free from malignant disease, which, however, was known among the few white settlers and the neighbouring Boers. But with the advent of the diamond industry syphilis invaded the Basutos, and then, after a time, malignant disease, especially between 30 and 40 years of age, appeared. Later, tuberculosis, particularly of the lungs, became increasingly frequent, as has often been observed in similar circumstances. Lieut.-Colonel de Pury, after quoting the familiar example of syphilis as a disposing factor in carcinoma of the lip and tongue, records a family with many instances of the two diseases combined, and expresses his belief in a hereditary syphilitic diathesis for malignant disease.

Universities and Colleges.

UNIVERSITY OF LONDON.

AT a meeting of the Senate on March 20th Professor A. D. Waller, F.R.S., and Dr. S. Russell Wells were reappointed director and treasurer respectively of the Physiological Laboratory. Dr. E. W. G. Masterman has been added to the panel of University Extension Lecturers. The Gilchrist Studentship for Women has been awarded to Mary K. F. Lander of the London (Royal Free Hospital) School of Medicine for Women.

UNIVERSITY OF DURHAM.

ARRANGEMENTS are now completed for the completion of the register of parliamentary electors of the University of Durham. All graduates, including those who have taken a bachelor's degree, are qualified to be registered. Particulars will be sent on application (enclosing a stamped addressed envelope of foolscap size) to the Registrar, University Offices, Durham.

At the Convocation held on March 30th the following degrees were conferred:

M.D.—C. E. De Silva, J. R. D. Holtby, H. D. Senior, C. R. Wilkins.
M.D. FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.—C. U. Ind.
M.B.—E. G. Anderson, J. A. Berry, J. Gilmour, H. Sterne-Howitt.
B.S.—E. G. Anderson, J. A. Berry, J. Gilmour, I. Soliman, H. Sterne Howitt.

UNIVERSITY OF EDINBURGH.

AT the spring graduation ceremony on April 4th the following degrees were conferred:

M.B., B.Ch.—Eva M. Clark, H. R. Goldberg, W. A. Gray, Martha L. Hamilton, W. G. Hughes, G. Lange, D. O. Macdonald, H. B. Mackenzie, A. R. C. McKerrow, J. S. Mann, D. J. Micah, J. C. Morris, Annie C. Roberts, G. M. S. Smith.

* With second class honours.

UNIVERSITY OF GLASGOW.

THE following degrees were conferred on April 4th:

M.B., Ch.B.—A. B. Stich, A. Kennedy, Lydia I. H. Torrance, Annetta G. T. Anderson, T. W. Carstairs, M. Chalmers, Grace Chatterton, A. E. Crochrane, Margaret O'R. Gallacher, Mary B. Gillespie, G. O. Grant, J. C. Hendrie, Alison M. Hunter, Margaret T. McGeorge, W. S. L. McLeish, D. Macqueen, J. Nicolson, Agnes P. Routledge, Dorothea H. Suttie, J. J. Treanor, W. A. Walker, J. A. White, G. Young.

* With commendation.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

THIRD EXAMINATION.—J. H. Bain, T. A. du Toit, J. A. S. Campbell, G. O. Field, D. D. Fernandes, J. Campbell, A. F. Caddell, J. B. W. Telford, A. A. Lamaletie, T. F. Kelly, A. Gold, J. Murray, S. H. Waddy. Pathology: H. A. Newton, R. McKinnon. Materia Medica: D. Mackay, W. Campbell, W. Barton, Jessie M. L. Wright, J. MacGlasheen, J. R. McCubbing, Agnes M. Hill, Janet A. A. Saug, R. Smith, Gracie O. D. Evans, Anup Singh Narula, G. M. S. Lindsay.

FINAL EXAMINATION.—H. W. Howatson, S. A. Faulkner, A. E. Hempleman, Indra-narayan Borrah, G. H. C. Harding, A. P. Robb, D. C. Howard, R. H. Malome, P. Vertannes, E. E. Bronstorph, D. M. MacLeod, J. H. Blackburn, A. Parker, T. H. J. Douglas, H. Millar. Surgery: A. S. Hughes. Midwifery: J. J. van Nierkerk, D. A. Walpole, A. H. B. Hudson, R. J. Patchett, A. S. Hughes. Medical Jurisprudence: H. McIlroy, Jatindra Kumar Sen, N. J. Patterson, I. R. MacPhail, R. J. Patchett, R. C. Bell, R. A. Cooper.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

"BEAT" HAND.

THE correspondent who asked a question on this subject in the JOURNAL of February 2nd criticizes the reply given and reinforces his objection by quoting various authorities. We, however, cannot accept his view. The interpretation of the law given in our answer is that adopted, we believe, by every county court judge in Great Britain and Ireland. The question is purely one of law, and the Boilermakers' Society would no doubt be able to get an opinion or raise a test case. The other alternative would be to collect evidence that "beat" hand is specific to the employment of riveters, and obtain a modification of the law.

REST IN SANATORIUM TREATMENT.

DR. EDWARD E. PREST (Ayrshire Sanatorium, New Cumnock) writes: We need not be surprised that sanatorium treatment is so often a failure, when apparently it is so little understood. In your issue of April 6th Captain Morriston Davies makes the following statement: "The avoidance of reinfection and intercurrent respiratory infections, the hygienic life, and the use of exercise, are its chief weapons." If it be remembered that rest is the most important therapeutic factor in the treatment of early cases of pulmonary tuberculosis, failures when this is not enforced are easily explicable.

TREATMENT OF LEPROSY.

WE have received the following cablegram from Dr. Emanuel Roberts of Colombo, Ceylon: "Have discovered specific for leprosy; report of cases cured and progressing will follow."

MOSQUITOS: OILING OF PONDS.

C. Y. suggests that an article by Dr. W. M. McDonald, M.O.H. Antigua, B.W.I., in the *Journal of Tropical Medicine* of November, 1916, should be consulted as to the various anti-mosquito measures, including the application of oil.

TREATMENT OF MENINGITIS.

CAPTAIN H. M. CADE, R.A.M.C. (Officer in Charge, District Cerebro-spinal Fever Laboratory, Ipswich), desires to learn from Mrs. Fysh in what forms of meningitis she recommends as treatment the application of tincture of iodine to the shaven crown (p. 416). In the three cases (out of four) which she claims to have saved in Colombo, was the diagnosis made on clinical grounds only or on the chemical, cytological, and bacteriological examination of the cerebro-spinal fluid? The diagnosis of meningitis, he says, can only be confirmed by the results of lumbar puncture, and the nature of the infection can only be decided by adopting this method. Of all forms of meningitis, that caused by the meningococcus seems to be the least fatal, especially if treated on rational grounds. He would not care to rely on painting the head with tincture of iodine in a case of meningococcal meningitis, when early lumbar puncture and the intrathecal injection of a specific serum holds out such good prospects of a cure, except in those fulminating cases which are invariably fatal.

CAUSATION OF SEX IN MAN.

DR. W. E. ROPER SAUNDERS (Backworth, Northumberland) sends the following case, which may be added to the other records elicited by the review of Dr. Rumley Dawson's book on the causation of sex in man published on January 5th: Mrs. S. was operated on when she was 16 years old for an ovarian tumour, and the ovary was, according to the operator, completely removed. She was informed at the time of the operation that whatever children she had would always be of the same sex. When 23 years of age she was delivered of a male infant, and three years later, on April 2nd, 1918, to her great surprise of a female child. I think that a case like this goes some way to prove that a single ovary—the right in this case—provides ova giving rise to children of both sexes, and that the actual factor determining sex is yet to be found.

PARIS HOSPITALS AND THE THEATRE TAX.

L'ASSISTANCE PUBLIQUE, which is responsible for the administration of Paris hospitals, has long derived part of its revenue from a tax on public performance. In 1908 it received about £200,000; in 1913 about £300,000. During the early months of

the war the theatres were closed, and the receipts fell in 1914 to about £150,000, and in 1915 to about £100,000. In 1916 they rose to £190,000, and in 1917 to £250,000.

APPEAL FOR THE FAMILY OF THE LATE DR. KITE.

DR. ARTHUR E. GILES (10, Upper Wimpole Street, W.) and the Rev. P. M. WATHEN (Welwyn, Herts) write: We shall be obliged if you will allow us, through your columns, to thank those who have so kindly contributed to this fund, and to say that we will gladly welcome any further contributions, as the amount so far received still falls a good deal short of what is required to give adequate help to Mrs. Kite and her daughters. The amounts received are as follows:

	£	s.	d.
"A Country Brother," Bridge of Allan	1 0 0
"A Nottingham Practitioner"	1 0 0
Dr. Josiah Beddow, Exeter	1 1 0
Dr. John Brown, Blackpool	0 10 6
Dr. Abraham Cohen, London	1 1 0
Dr. George Crichton, London	0 7 0
Dr. Wm. Davidson, Bournemouth	0 10 6
Dr. Arthur Giles, London	10 10 0
Mr. Cecil Graham, London	0 10 6
Dr. C. O. Hawthorne, London	1 1 0
Dr. C. F. Leslie-Splinks, Bournemouth	0 10 6
Dr. Mary Rathbone, Liverpool	2 2 0
Dr. Septimus Sunderland, London	1 1 0

THE JOINTED-POLE TRENCH STRETCHER.

MAJOR G. H. COLT, R.A.M.C. (T.F.), writes to draw attention to a jointed-pole trench stretcher (see figure) designed by him for use in narrow, traversed, or winding trenches from 18 in. to 28 in. wide, that is to say, in the type of front line trench in which all devices so far tried for moving a badly gassed or wounded man have failed. In a trench less than 28 in. wide bearers cannot pass a right-angled corner when carrying a short-poled stretcher; while owing to its irregular movements and ill-balanced weight the strain on them is great, and their hands are apt to be knocked about. Moreover, the patient is carried upright, is often badly shaken by the tilting, and may even fall out. Hence, his removal is often left until nightfall. With the jointed-pole stretcher he can be moved at once, and

most of the difficulties are overcome. He is carried comfortably in the Fowler position, he cannot fall out, and his position is the best for all injuries as far down as the knee. For injuries below the knee a splint may be used. In this apparatus the weight is evenly distributed between the two bearers, and is borne by a direct shoulder suspension without neck constriction, while the heads of the bearers are free to aid the patient or save themselves on uneven ground. The total weight of the apparatus is 22 lb. The original account of the measurements and experiments relating to the matter were published in the *Lancet* of January 22nd, 1916. In the illustration the apparatus is shown turning a right-angled corner. The chest band for the front of the chest should have been drawn horizontal. The apparatus is manufactured by Messrs. Waring and Gillow, 164, Oxford Street, W.1.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

A Clinical Lecture ON THE BAD HABIT OF VAGINAL DOUCHING.

GIVEN AT THE MANCHESTER ROYAL INFIRMARY.

BY

W. E. FOTHERGILL, M.A., B.Sc., M.D.

THE inventor of the vaginal douche-can was no friend to womankind, for the result of his ingenuity has, on the whole, been a curse rather than a blessing. Just as there was a pessary age, characterized by the haphazard use of pessaries in the treatment of the minor ailments of women, so there has been a long period of indiscriminate douching which has not yet reached its belated end. Soon after the discovery of micro-organisms as a cause of disease, the newborn infection idea began to put out of joint the nose of its little elder brother the displacement theory, and it was surmised that infection must be to blame for most of the minor pelvic troubles. Less was heard about versions and flexions, and those blessed words "endometritis" and "ovaritis" came into fashion as diagnoses. Less ingenuity was bestowed upon the adaptation of pessaries, and much trouble began to be expended on the disinfection of the vagina by douching, regardless of the fact that it was seldom infected. Not only was the douche used for the cure of supposed infection, but also for its prevention. For some time it was even the custom to swill the vagina with antiseptic lotions before, during, and after labour. The results were so deplorable that this practice was soon dropped. I well remember being told by the late Professor Sir Alexander Russell Simpson, in the year 1895, to tear down from the walls of the Edinburgh Maternity Hospital the instructions for routine douching which had been in force for a period during which the hospital had to be closed more than once on account of epidemics of puerperal pelvic infection.

For a time douching remained under the control of the medical profession; but then the general public took the bit in its teeth and began buying douche-cans on its own account. It has gone on doing so ever since, and the pernicious but apparently seductive habit of antiseptic douching is now generally begun on the advice of an elderly relative. A patient, now aged 43, began douching herself with alum water at the age of 19, on the advice of her stepmother. She had the "whites" at the time, and the alum naturally made the complaint worse. She married and went on douching, but changed from alum to Condy's fluid on the suggestion of her mother-in-law. For the last fifteen years she has douched herself night and morning; and after trying various other irritants, is now using a lysol substitute which makes her smart badly. The vulva, vagina and cervix are now "red raw" and streaming with discharge. She has had menorrhagia and dysmenorrhoea for several years, and recently has suffered continuous pelvic discomfort.

A healthy young lady mentioned to her mother-in-law that she had a slight excess of normal vaginal discharge just before and after the menstrual periods. She was provided by this relative with a douche-can, which she used every day for two years, the "whites" becoming worse and worse all the time. The discharge became constant and slimy in character, the menstrual flow was increased in duration and quantity. The patient began to have congestive dysmenorrhoea, and later there was dull aching pain throughout the intermenstrual intervals. When the douching was stopped the symptoms gradually disappeared, the last first and the first last. Cases like these are not exceptional; they crop up every day both in hospital and in private practice. Indeed, every patient who complains of minor pelvic ailments should be asked whether she douches or not; and, if she says "Yes," should be told to stop it. Nurses often douche without any instructions; sometimes because they think it is the correct thing to do, and at other times because their patients seem to expect it. This must also be stopped.

ANTISEPTIC AND MEDICATED DOUCHES.

In considering the action of douches we must remember that the vaginal surface has no glands, and is not a mucous

membrane, but is covered by stratified squamous epithelium, which, though very strong and resistant to infection, is, so to speak, not quite waterproof. Thus the vaginal secretion is simply serum which exudes from the surface of the squamous epithelium, and which acquires its normal creamy appearance by admixture with leucocytes and epithelial debris. Sliminess of the vaginal discharge is due to an excess of mucus which comes from the lining of the uterus and not from the vaginal wall. Again, it must be remembered that the normal vaginal secretion is definitely acid in reaction, and that this acidity inhibits the life of most septic and pathogenic organisms. Thus the normal content of the vagina is a barrier to ascending infections, and it is generally sufficient to protect the uterus. For instance, after the experimental introduction of streptococci, the healthy vagina has been shown to be free from these organisms in the course of a few hours. In fact, most vaginal infections quickly cure themselves if left alone, and many cases cure themselves in spite of a certain amount of vaginal douching, which, in these cases, secures the credit that should by right belong to the unaided vagina.

But douching does actual harm in more ways than one: for it washes away the normal acid secretion; it kills the acid-producing bacteria which are the normal inhabitants of the vagina; it kills the superficial layers of cells, and irritates the subjacent layers. Further, it promotes hyperaemia of the parts, and thus increases the quantity of the secretion, favours menorrhagia, congestive dysmenorrhoea, and intermenstrual congestive pain. This explains the fact that the woman who douches much never gets rid of her vaginal discharge, and generally has other complaints in addition.

The above remarks refer to chronic douching; are there any excuses for what might be called acute or subacute douching? Take septic infection of the uterine cavity after abortion or labour. In these cases vaginal douching clearly does not touch the spot at all, and intrauterine douching is positively dangerous, as it sometimes causes fatal peritonitis by forcing septic material and noxious antiseptics through the tubes into the peritoneal cavity. The proper way to treat uterine sepsis is to dry-clean the uterine cavity thoroughly, using a general anaesthetic if necessary; to apply concentrated antiseptics with no excess of fluid; and thereafter to leave the uterus and vagina severely alone. Take gonorrhoeal infection of the vulva. If it is treated by douching, the infection is very likely to be carried up through the vagina to the cervix, whence the gonococcus has a clear run over the mucous lining of both uterus and tubes. Again, when the cervical canal is once infected, douching is futile, and proper disinfection under anaesthesia is the only method likely to be effective. In fact, there is no "home treatment" for uterine gonorrhoea in women. Yet there are still some who supply their patients with the inevitable douche-can and order copious and frequent libations of Condy's fluid, while in one clinic women are actually advised to wash out their own bladders!

Though it appears that antiseptic and medicated douches might well be dispensed with altogether, there are exceptions to the rule. Thus, in the palliative treatment of cancer of the uterus, disinfectant and deodorant solutions must be used. Again, when preparing a prolapsed and ulcerated vagina or cervix for operation, the nurse will give one or two mildly antiseptic douches every day for a week or ten days, during which the patient is kept in bed and the vagina lightly packed. After vaginal operations, also, a few antiseptic douches are useful on those rare occasions in which the incisions become septic. In such cases the indication is definite. But often there is no indication at all. The patient says, "Doctor, I have a vaginal discharge." The doctor makes no examination, but says, "Get a douche-can," and orders alum, iodine, lysol, mercuric perchloride, boracic acid, zinc sulphate—anything, in short, that occurs to him. The patient begins douching, the doctor forgets to stop her, and she goes on with it for years. The idea that a vaginal discharge must be infective is very widespread and persistent, though it may be far from correct. When a woman complains of a discharge it is most frequently "the whites," namely, excess of the normal creamy vaginal discharge. This is common before and after menstrual periods in perfectly healthy persons. Its persistence throughout the intermenstrual period is often an expression of a low general condition;

but some women have more vaginal secretion than enough throughout life, and quite apart from variations in health. Any form of local treatment aggravates "the whites," but the condition often disappears with improvement in health brought about either by general treatment or by change of air and scene. When the vaginal discharge is slimy, the uterus is secreting too much mucus, and this is increased by douching or any other local treatment of the vagina. If any local treatment is required it is curettage of the uterus; but this generally fails unless the general muscular and vascular tone is improved at the same time.

HOT DOUCHES.

Hot douching is often ordered in cases of menorrhagia and other kinds of uterine bleeding. It is true that the application of water at a temperature of about 120° F. contracts the blood vessels and leaves them in a state of contraction which lasts for from half to three-quarters of an hour. But water which is hot enough to produce this effect is uncomfortably hot for the skin round the vulva and anus as it flows out of the vagina. It is possible, given a strong-minded nurse and a weak-minded patient, that really hot douches may sometimes be given for several days together. But in practice, when the hot douche is ordered, it is given warm; and water at 100° F. increases pelvic hyperaemia and so increases uterine bleeding. Thus it happens that when hot douching is ordered for menorrhagia, the patient really receives treatment by warm douching, and the bleeding gets worse instead of better. The hot douche, therefore, should probably be kept for use in obstetric haemorrhage, in which it is doubtless very useful on occasions.

WARM DOUCHES.

Under certain circumstances it is highly desirable to increase pelvic hyperaemia, and for this purpose the prolonged warm douche is useful if given under proper supervision and for a limited period. The typical case for this treatment is a patient who is recovering from pelvic cellulitis following infection of a torn cervix. There is a more or less massive deposit of inflammatory exudate in the pelvic cellular tissue. Its absorption must be favoured in order to avoid permanent fixation of the pelvic organs. The same holds true also in reference to inflammatory deposits in other pelvic tissues and organs. Thus, in the subacute phases of pelvic infection, vaginal douching is seen at its best. A slow stream of normal saline solution at a temperature of 100° F. to, say, 105° F., kept up for ten or twelve minutes once or twice a day for two or three weeks, forms a part of the proper treatment of these cases. But it must be done with the patient lying on her back, for when a douche is given with the patient sitting up the flow of water never separates the vaginal walls, but simply runs out beside the douche nozzle without even washing the vaginal surface. To act as a poultice or fomentation the water must balloon the vagina, and this it does only when the patient is on her back.

CONCLUSION AND SUMMARY.

You may have noticed that some people cannot learn at all, that some can learn only by their own experience, and that some are sufficiently astute to profit by the experience of others. To those of you who care to try the results of my experience I offer the following practical hints:

1. Do not allow patients to douche themselves at all; but, when you have a definite reason for douching, let a nurse do it.
2. Do not use antiseptic douches unless there are germs to be killed in the vagina.
3. Remember that vulvitis is common but vaginitis is rare.
4. When you wish to apply antiseptic lotions to the vulva tell the patient not to douche herself with the lotion but to put it in a large bowl and sit in it.
5. Do not order hot douches (120° F.) in cases of menorrhagia and metrorrhagia.
6. Do not douche for leucorrhoea either creamy or slimy.
7. Do not douche for aches and pains in the pelvis which are not due to pelvic infection.
8. Use warm douches (100° to 105° F.) as you would use poultices or hot fomentations, in cases of pelvic

infection which are neither too acute nor too chronic to be improved by the production of temporary local hyperaemia.

THE TREATMENT OF FURUNCULOSIS AND OTHER DEEP-SEATED COCCOGENIC INFECTIONS BY COLLOSOL MANGANESE.

By Sir MALCOLM MORRIS, K.C.V.O.

THE routine treatment of boils and other deep-seated coccogenic affections, such as ecthymatous impetigo and some cases of acne, is often most disappointing. In the treatment of furunculosis some authorities lay stress upon constitutional treatment; and in certain cases, as where the process is associated with diabetes, this is obviously important. Others rely rather upon the local application of antiseptic agents, with the view of absorbing the boils. But both forms of treatment frequently fail. In many instances boils to boils succeed, and when at last the dismal procession ends, this often appears to be less the result of treatment than because the disease has run its natural course. This is true of vaccine-therapy, as well as of the earlier methods. Sometimes the inoculations appear to arrest the disease; in other cases they signally fail to do so.

In these circumstances it seemed to me desirable to give a trial to the treatment by collosol manganese instituted at the General Hospital at Etaples by Mr. J. E. R. McDonagh.¹ The results in all my cases are so remarkable as, in my judgement, to demand publication.

It should be premised that at first the collosol manganese (Crookes) was used in the form of a single solution. Afterwards it was employed in the improved form of two solutions, which had to be mixed in the syringe; of this, much smaller doses (about one-half) suffice.

CASE I.

The patient, a medical man, came to me on November 24th, 1917, with large, deep-seated boils on the hairy part of the face, which he believed to be an infection from a carbuncle in a diabetic patient, from whom he had contracted a septic whitlow. Culture showed that the micro-organism was the *Staphylococcus pyogenes aureus*, and an autogenous vaccine was prepared, with which he was inoculated on November 30th. By this time a boil on the right cheek had enlarged to the size of a Tangerine orange; there was much oedema of the face and eyelids and great pain. On December 6th pus was discharged and the pain relieved; but during the next seven weeks boils continued to appear at intervals, usually in groups of four or five, on one or both sides of the face. By January 14th eleven injections of vaccine had been given, antiseptic lotions and ointments being also applied. On January 31st the patient consulted me again and I advised the injection of collosol manganese. The first injection was given the next day. "Improvement," to quote from the patient's own notes, "began on the third day afterwards. Subsequent boils, which continued to appear for a further fourteen days, were not painful, and many of them aborted without pus formation. In all, four injections were given—1.5 c.cm. on January 31st, 2.5 c.cm. on February 5th, 3 c.cm. on February 12th, and 1 c.cm. on February 28th; the first and second in the gluteus, the third and fourth in the flank. In the first three the old preparation was used; in the fourth the new. By March 5th I was able to report 'All clear.' From November 30th to January 31st, while the vaccine was being given, thirty-three carbuncular boils appeared; after the collosol manganese was begun there were only seven, the last appearing on February 20th, three weeks after this treatment was begun." The patient's general health also greatly improved; he began to feel better within a week of the first manganese injection.

CASE II.

The patient was an army captain who was subject to acne. When the first collosol manganese injection (0.5 c.cm. of the new preparation) was given, on March 13th, he had been in hospital four months with facial boils and acute impetigo contagiosa of the same region. During that time he had had vaccine injections, and various antiseptics had been applied, without result. Another manganese injection (0.5 c.cm.) was given on March 16th, and a third (1 c.cm.) on March 19th. By this time all the lesions had cleared up.

CASE III.

I saw the patient, a lady, for the first time on February 16th. She had extensive follicular impetigo of the scalp, which began in the preceding October, and had gradually become more severe. When she came to me she complained of great pain from small multiple deep abscesses. There was a good

deal of oedema, and the posterior cervical glands were enlarged. On February 18th 1.5 c.cm. of the old collosol manganese solution was injected. By February 22nd the lesions were beginning to clear up, the pain was nearly gone, and the general health distinctly better. A second injection (0.5 c.cm. of the new preparation) was given, and a third (1 c.cm.) three days later. By this time further improvement was manifest, and the patient was able to sleep. No further injection was required, and by March 19th recovery was complete, the only trace of the disease consisting in small bald areas on the site of the lesions.

CASE IV.

The patient, a major, came to me first on February 22nd, when he had twelve large indurated boils on the buttocks, thighs, and axilla. The infection began three months before, following scabies. A dose of the old collosol manganese solution (1.5 c.cm.) was injected into the buttock. Three days later, when a second dose (2 c.cm.) was given, the boils were subsiding, and the general health had improved. By March 1st there was further improvement; all the smaller boils had retrogressed, a large indurated lesion in the left axilla was much less painful, and the core had come away without the usual trouble. A third injection (1 c.cm. of the new preparation) was given. The next day all the boils had cleared up, but there was a fresh suppurating lesion over the right patella. Further injections (one of 0.5 and two of 1 c.cm.) were given on March 5th, 8th, and 11th. By March 14th the boil on the knee had subsided; but a fresh boil appeared on the right thigh. Three more injections followed, on March 18th, 21st, and 25th, and the case is now well.

The results of the new treatment, even in the last and most obdurate of the four cases, speak for themselves. But emphasis must be laid upon the great improvement in the patient's general health which was observable in every case within a few days of the first injection. It may have been due in part to the diminished pain and the heightened expectation of recovery; but no one who saw the patients could, I think, regard this as the full explanation. It was especially noticeable in the second case, in which the patient was suffering from shell shock. The injections, except two of those in the first case, were all intramuscular. They were followed by no reaction.

THE CHANCE OF RECOVERING DYSENTERY BACILLI FROM THE STOOLS ACCORDING TO THE TIME ELAPSING SINCE THE ONSET OF THE DISEASE.

EXPERIENCE AT A BASE HOSPITAL IN FRANCE.

BY

LIEUT.-COLONEL C. J. MARTIN, F.R.S., A.A.M.C.,

AND

SISTER F. E. WILLIAMS, A.A.N.S.

Prior to the war the notion seems to have been widespread that the bacteriological diagnosis of dysentery was as satisfactory as, say, that of diphtheria, and measures for the control of epidemics have been founded to some extent on this assumption. Our experience of laboratory work in the Eastern Mediterranean and Egypt in 1915 and 1916, however, led us to the conclusion that the chance of recovering dysentery bacilli from the stools was, after the first few days of the disease, a small one.

Similar experience seems to have been gathered elsewhere. Kolle and his co-workers¹ give an account of the bacteriology of an epidemic on the Russo-German front with which they dealt. They isolated *B. dysenteriae* Shiga from such a minute fraction of the samples examined that they came to the conclusion that, notwithstanding the general clinical resemblance to dysentery of this type, they must have had to deal with an outbreak from some other cause. Seligmann and Cossmann² also obtained very unsatisfactory results when working at a base hospital in Austria. They state that "they nearly always failed to recover dysentery bacilli" in undoubted clinical cases of dysentery. During eight months' work they recovered a dysentery bacillus but fifteen times out of "hundreds of attempts."

Later Seligmann was removed to a laboratory nearer the front, where he had opportunity to examine material from the recently evacuated sick. Under these conditions the results were entirely different, *B. dysenteriae* Shiga being

recovered in 38 per cent. of cases examined. Seligmann does not state the actual number of examinations which he made, but for one month (June, 1915) he gives the percentage positive findings according to the state of the illness. These were:

First week	...	70 per cent. successful recoveries.
Second week	...	53 per cent. " "
Third week	...	18 per cent. " "
Fourth week and later	...	Nil.

In the case of patients admitted to this hospital, the onset of the disease has been from one day to two months previously. The same routine has been applied in all cases, so we have a number of observations bearing on this point.

The methods employed were to plate out a suitable dilution of the stool, if homogeneous, upon a plate of MacConkey's lactose-bile-salt-peptone-agar. If the stool contained any mucus, a piece was chosen, washed in sterile water, broken up in the same, and some drops sown on the plate and well rubbed over with a glass rod. The amount chosen was so as to produce about 500 colonies on the plate. If, next day, the number of colonies was so great as to be unmanageable or so few as not to provide a sufficient sample, a second plate was made to remedy the defect, a sample of the stool having been kept in the icebox meantime to provide against the above contingencies.

After eighteen to twenty hours for growth the plates were scrutinized, and if they showed positive dysentery colonies, samples of these were picked off and sown into tubes of warm broth. Four hours later they were examined for motility and sown into tubes of peptone water containing 1 per cent. of lactose, glucose, and mannite respectively, and on the surface of an agar slope and placed in the incubator overnight.

Next morning, if the actions in the various carbohydrate media were typical, the growth on the agar slope was emulsified and its agglutinability tested against dilutions of appropriate agglutinating serums up to 1 in 1,000 by the macroscopic method.

It was rare to find *B. dysenteriae* the preponderating organism on the plates. This occurred sometimes when perfectly fresh mucopus obtained from a patient in the first or second day of the disease was the material sown. Usually when dysentery bacilli were present the number of colonies varied between 1 and 20 on a plate showing 500 to 1,000 other organisms.

To ascertain whether MacConkey plates offered any hindrance to the growth of *B. dysenteriae* Shiga or *B. dysenteriae* Flexner, we spread the same volume of a broth containing a few bacilli which had been just recovered from a dysentery stool and not subjected to a subculture upon a series of MacConkey plates and also upon plates of ordinary nutrient agar. The results on incubation were as follows:

TABLE I.

Emulsion of <i>B. dysenteriae</i> Shiga sown.		Emulsion of <i>B. dysenteriae</i> Flexner (Y).	
No. of Colonies on Nutrient Agar.	No. of Colonies on MacConkey Media.	No. of Colonies on Nutrient Agar.	No. of Colonies on MacConkey Media.
1. 530	280	1. 496	676
2. 546	584	2. 259	554
3. 236	450	3. 290	320
1,312	1,314	1,045	1,550

The inhibitory action of the bile salts in the MacConkey media evidently did not prevent the colonies of dysentery bacilli appearing. They were, however, of smaller size upon the MacConkey plates, the mean size of the Shiga colonies being 1.07 mm. and of the Flexner 0.82 mm., as against 1.2 mm. and 1.34 mm. respectively upon nutrient agar after the same interval for growth to occur.

We feel confident that whenever dysentery bacilli were present in the material plated to the extent of about 1 to 500 other organisms capable of growing upon a MacConkey plate, they were discovered. An abbreviation of the ritual sketched above does not appear to be permissible, and resort to agglutination tests without ascertaining that the

organism under examination satisfies the essential cultural and biochemical characteristics of one or other of the dysentery bacilli is dangerous, particularly in the case of the mannite-fermenting group of dysentery organisms, for high titre serums prepared against this group are not specific in moderate dilution, and will agglutinate several kinds of coliform bacteria.

Innocence of this fact has led to much confusion in some military laboratories, as witness the discussion at the Medical Society of Vienna, April 30th, 1915, upon a paper by Falta and Kohn.⁸

From June to December, 1917, we made upwards of 1,200 efforts to recover dysentery bacilli from the stools of patients at various periods of their illness. The results of these attempts are arranged in Table II, in the relation to the time intervening between the onset of the disease and the examination. We have not included in the figures thus analysed the cases in which there was not clear evidence that the patient was manifesting or had manifested dysenteric symptoms, and all cases in which *E. histolytica*, either active or encysted, were discovered have been excluded.

TABLE II.—Results of 1,050 Efforts to Recover Dysentery Bacilli from Stools at Various Stages of the Disease, June–December, 1917.

Graph representing success in recovering dysentery bacilli from the stools at different periods after the onset of the disease (1,050 examinations).

CONCLUSION.

Our chance of recovering dysentery bacilli rapidly diminished after the first few days. This appeared to be the case whether the stools remained characteristically dysenteric or not.

The muco-pus and epithelial debris discharged in the milder pathological condition, and the necrosed coagulated superficial layers of the mucous membrane in the more serious is, except in the earliest stages of the disease, invaded by hosts of intestinal organisms, which soon overwhelm the dysentery bacilli originally present. This places a serious limit on the value of a bacteriological diagnosis of dysentery. If reliance had been placed on the results of one examination but 15 per cent. would have been discovered.

TWO FATAL CASES OF ICTERUS GRAVIS FOLLOWING INJECTIONS OF NOVARSENOBILLON.

BY

LIEUT.-COLONEL P. C. FENWICK, C.M.G., N.Z.M.C.,

COMMANDING N.Z. NO. — GENERAL HOSPITAL, CORDFORD;

CAPTAIN G. B. SWEET, AND CAPTAIN E. C. LOWE,
N.Z.M.C. N.Z.M.C.

The two cases here recorded are, we think, of distinct interest at the present time, when so many cases of syphilis are under treatment by arsenical drugs.

CASE I.

A soldier, aged 26, was admitted on March 22nd, 1917, with slight jaundice. He stated that he felt well, with the exception of a slight pain in the right hypochondrium, and only reported sick because he was told he looked yellow. He gave a history of recurrent attacks of abdominal pain for three years, occurring every three or four months and lasting three or four days.

On admission his skin and corneae were stained yellow. There was no abdominal pain or tenderness and no vomiting. The bowels were constipated; the urine contained bile in considerable amount, but no albumin or sugar. Liver dullness $4\frac{1}{2}$ inches in nipple line.

He had been under treatment for syphilis. Captain Brown, N.Z.M.C., in charge of V.D. section, reported that the man was admitted on January 22nd, 1917, with a large sloughing, discharging sore on right side of foreskin and also a small penile sore. There was some inguinal adenitis, but no rash; spirochaetes were present. The blood test was weakly positive. He was treated with novarsenobillon as follows: January 23rd, 0.45 gram; February 15th, 0.6; February 22nd, 0.6; March 1st, 0.9; March 8th, 0.9; March 15th, 0.6. He received also five mercurial injections. The sore had healed on March 1st. While in hospital he developed inguinal bubo, which was tapped twice. The result of the last blood test was negative.

The jaundice steadily increased, and on March 28th the liver dullness measured three inches. Vomiting began on April 1st, the jaundice grew more intense, the urine became almost black in colour, and the pulse slow and weak. He died on April 5th.

Post-mortem Observations.

A post-mortem examination was made by Captain E. C. Lowe, from whose report it appears that the heart was normal, save for bile staining of the valves and vessel walls and small petechiae on the walls of the left ventricle. The lungs were normal, except for hypostatic congestion, which was intense on the left side. The spleen was not enlarged and appeared normal on section. The intestines were not ulcerated, but the jejunum showed small petechiae and was deeply bile stained, and the duodenum, which contained a dark greenish bilious fluid, was markedly injected. The gastric mucosa was bile stained and injected, markedly at the pyloric end; there were no haemorrhages. The pancreas was slightly congested, but otherwise normal. Both kidneys appeared normal, save for bile staining. The meninges were bile stained, but otherwise the cranial contents were normal. The note upon the liver and gall bladder was as follows:

Liver.—Smaller than normal. Weighed 2 lb. 2½ oz., and was deeply bile stained. Some mottling over anterior surface, most marked on the right lobe. No unevenness of surface; edges sharp; no inflammatory adhesions; left lobe small. On section right lobe cuts easily and shows deep yellow degeneration in irregular areas mostly confined to anterior surface and anterior border for the distance of an inch inwards. The centre of the organ comparatively free, of yellow coloration, but showing a nutmeg appearance of central congestion and periobular contrast. Left lobe shows much less sign of degeneration. Cuts normally. Slight sign of yellow degeneration. No nutmeg appearance.

Gall Bladder.—Normal. Contains a drachm and a half of bile. Ducts free and patent. No signs of gall stones or cholecystitis.

Microscopical Examination.

Captain F. L. Armitage reported as follows:

Liver.—Sections show marked excess of fibrous tissue throughout, especially round Glisson's capsule, but also spreading into the gland tubules. Islets of healthy liver tissue persist, with only a small amount of fatty degeneration in places. No active necrosis, but inflammatory changes are seen everywhere. It appears to be some variety of cirrhosis of the liver and not yellow atrophy.

Spleen.—Some excess of fibrous tissue in the trabeculae and pulp, but no gross change.

Kidney.—There is so much post-mortem change that it is difficult to say how much real lesion there may be. The consolidated tubules show marked necrosis, probably indicating a tubal nephritis. A few small cysts are present.

Note on the Histology.

By Professor F. W. ANDREWES, F.R.S. (Major R.A.M.C.T.).

The liver is partly bright green, partly deep red, and the appearances are different in the two areas.

Green Part.—Here the changes are less advanced than in the red part. There is a cirrhosis of multilobular type of fairly recent standing, but more than I should have thought possible in seven weeks. The young fibrous tissue is infiltrated with round cells. The hepatic cells show considerable degenerative change, with some fatty infiltration, but the material had been put in spirit, which spoiled it for Sudan III staining. There is a catarrhal cholangitis of the larger bile ducts.

Red Parts.—Here there is a little coarse cirrhosis, but the liver cells are almost completely degenerate, leaving only a loose fibrous stroma, with an interstitial inflammatory infiltration. Shrunken remains of the liver cells are seen. The bile ducts are better preserved. The red colour is due to extravasation of blood corpuscles in the centres of the lobules. This extravasation is extreme, masking the structure of the tissues, and is quite sharply defined, the periphery of the lobules being free. Instead of being due to dilated capillaries, as in ordinary nutmeg liver, the condition seems due to actual extravasation. I am unfamiliar with this appearance, which is very striking.

CASE II.

A soldier, aged 20, was admitted to hospital on January 24th, 1917, with left-sided pleurisy—not severe. At the end of February a suspicious ulcer appeared on the fraenum. A Wassermann test proved positive, and he was transferred to V.D. section on March 19th, when he had a round healed sore on the under side of the body of the penis, and general adenitis. The skin and mucosa were clear. The Wassermann reaction was "strong positive." Captain Brown reports that he was treated with novarsenobillon, 0.45 gram, on March 25th, and 0.6 on March 27th. He received also two mercurial injections. The blood test on March 31st was double positive. He developed a second attack of pleurisy, and on April 19th the left chest was aspirated and 60 oz. of clear fluid removed. He improved in health, and on May 2nd it was decided to continue the anti-syphilitic treatment and he was given novarsenobillon (0.60) and a second dose (0.60). On May 9th he was placed on an iodide-mercury mixture. On May 15th the Wassermann test was double positive, and on the following day another dose of novarsenobillon (0.60) was given. No further injections were given. On June 1st he was slightly jaundiced; he was kept in bed and the mercurial treatment discontinued.

On June 3rd the liver measured 5½ in. in the nipple line. There was no improvement in the jaundice. The urine (specific gravity 1015) contained no albumin, sugar, blood, bile, or arsenic (Marsh's and Reinsch's tests). On June 5th the icteric tinge had slightly increased; the urine was free from blood and arsenic, but bile was present. The jaundice and the amount of bile in the urine had increased by June 12th, and on the following day he vomited. On June 15th there was swelling of the right parotid without rise of temperature. There was some slight improvement for the next few days, but on June 22nd it was noted that the jaundice was more intense, that he vomited once or twice nearly every day, and that the liver dullness now measured 2½ in. in the nipple line. The temperature was subnormal. The urine (specific gravity 1010) contained bile, albumin, and epithelial and granular casts. It contained neither tyrosin nor leucin. The jaundice deepened, anorexia became marked, and on June 27th the breath had a peculiar rancid odour. The tongue was clean; there was no tenderness over the liver, stomach, or spleen. The area of absolute liver dullness had diminished to 2½ in. The spleen was not enlarged. The pleurisy had cleared up, but the pleura on the left side was thickened. His condition fluctuated on the following days; he passed large quantities of dark urine. On July 5th there was no absolute note of dullness on percussion over the liver; the relative dullness in the nipple line was 2 in. only. Later he became delirious and vomited occasionally but not incessantly. On July 9th he was semi-conscious. He died early on the morning of July 10th. All the urine was collected from June 22nd till death; the quantity varied from about 38 oz. during the first week to 11 oz. during the later days of his life. The daily quantity was concentrated to about 50 c.c.m., and submitted, with negative results, to Marsh's test, and on several occasions, on the advice of Mr. A. J. Ewins of the Lister Institute, to Norten-Koch's test. Arsenic was not detected in any one of the sixteen examinations, nor was it detected *post mortem* in the liver, kidney, lung, spleen, pancreas, or heart muscle. Two samples of urine were submitted to Dr. Hurtle (June 29th and July 2nd), who found no arsenic in either; he also examined a piece of liver without finding any trace of arsenic. Consultations with Colonel Davy, C.B., consulting physician in the command, were held on two occasions. Colonel Davy's note is as follows:

"I have seen — in consultation at Codford on two occasions—on June 7th and June 27th. He is suffering from jaundice, and has progressively become worse and worse, in spite of the most careful treatment. Some of his symptoms, especially first enlargement and then diminution of the liver dullness, rather look like acute yellow atrophy of the liver. Reviewing, however, the whole group of symptoms, they do not conform to the usual group found in this disease, and there is an absence of leucin and tyrosin, for which the urine has been carefully examined. It seems probable that we are dealing with a condition hitherto not recognized as any of the ordinary diseases, and the fact that he has had five injections of novarsenobillon raises grave suspicion that his condition is due to these injections."

Post-mortem Observations.

A *post-mortem* examination was made by Captain E. C. Lowe, from whose report it appears that the external surface was

deeply bile stained. The peritoneal cavity contained bile-stained fluid, and the retroperitoneal gland was enlarged, pulpy, and bile stained. The heart was normal. The right lung was normal, but the pleura on the left side was adherent throughout, and the lung compressed, semi-solid, and friable. The intestines were normal, as was the stomach, except for a few areas of deep injection. The spleen (weight 10 oz.) was enlarged, showing definite sclerotic mottling on the surface, and a puckered scar near the posterior border. Its substance was less friable than normal. The kidneys were bile stained, and the cortex appeared fibrotic and dense. The right weighed 9½ oz., the left 10 oz. The gall bladder was normal and contained normal bile. The note on the liver is as follows:

Liver (weight 36½ oz.).—Transverse diameter, 7½ in.; vertical measurement, 6½ in.; antero-posterior measurement, 3½ in. External surface shows white fibrotic linings. No external adhesions. Organ irregular and nodular to touch. Extensive greenish-brown areas of necrosis were found over the upper third of right lobe, in a few places on the left lobe, and almost entirely involving the middle lobe. On section, these areas show extensive necrosis of liver tissue of a greenish-brown colour and of soft consistency, irregularly separated by dark red fibrotic areas of very dense consistency.

Report on the Histology of Organs.

By Professor F. W. ANDREWES, F.R.S.

Liver.—Small, tough, with extensive greenish staining involving almost the whole organ, here and there red fibrotic areas. Not nodulated as in ordinary cirrhosis. There is a well-marked cirrhosis, multilobular in type, throughout the green part of the liver. The connective tissue is young and cellular, with lymphocytic infiltration. The liver cells show only a moderate degree of degeneration (much less than in the green parts from Case I), and there is very little fatty change in frozen sections stained with Sudan III. There is marked bile staining, and amorphous masses of biliverdin, bright green in colour, are present in the substance of many of the liver cells, as well as in the bile capillaries. The red areas in the liver show much more complete destruction of the liver cells and more advanced fibrosis. The red colour is due to haemorrhage. As in Case I, it is difficult at first sight to believe that such advanced cirrhosis could have occurred in six or seven weeks, but the similar change in both livers suggests that this may have been the case. The cirrhosis is not of syphilitic type.

Kidney.—Very large and deeply bile stained. There is a good deal of vascular congestion, but there is no glomerular nephritis, though the glomerular capsules contain a coagulable exudate. The epithelium of the convoluted tubules is greatly swollen and vacuolated, but the nuclear staining is mostly preserved, and there is very little fatty change in Sudan III sections. Bile-stained casts and granules are numerous, green with biliverdin.

Heart Muscle.—Slight fatty change only, in the form of granules about the poles of the nuclei.

Spleen and Retroperitoneal Gland.—No striking changes found.

These two cases resemble one another very closely in their history, clinical manifestations, and morbid anatomy.

Briefly stated, after receiving five doses of novarsenobillon followed by an interval (of seven and fourteen days respectively), they became jaundiced. At first the symptoms were mild, but the jaundice gradually deepened, the liver became greatly reduced in size, persistent vomiting occurred, and the patients died twenty-one and forty days respectively after the onset of symptoms. Autopsy showed an acute cirrhosis of the liver. Both were cases of primary syphilis and showed no secondary manifestations. Case No. 1 gave a negative Wassermann reaction at the conclusion of treatment, but Case No. 2 gave a double positive reaction on the last occasion on which it was taken.

That the cirrhotic condition of the liver was due to syphilis appears to be almost out of the question, as shown by Major Andrewes's report. In Case II he remarks on the appearance of the liver: "I am unfamiliar with this appearance." The clinical symptoms do not accurately agree with acute yellow atrophy of the liver, and the naked-eye and microscopical appearances of the liver are quite unlike what is found in this condition.

These two conditions being excluded, the question naturally arises whether these fatalities were due to chronic poisoning with arsenic. Inquiries were therefore made with a view to finding out whether similar cases had occurred at the N.Z.V.D. section or elsewhere.

Captain Falconer Brown, officer in charge of N.Z.V.D. section, states that he has treated 263 cases of syphilis with novarsenobillon, and the cases reported are the only ones followed by jaundice. Captain Robert W. McKenna, venereal specialist to 1st Western General Hospital, states that he has not met a single case of jaundice following treatment of syphilis by salvarsan and kharsivan, and

attributes his success to special precautions with regard to intervals between doses, etc.

Lieut.-Colonel Harrison, officer commanding Rochester Row Hospital, writes: "Jaundice occurs during treatment of syphilis with arsenical compounds in 0.6 per cent. of cases, and this symptom may last for four or five months."

In neither of the cases here reported was arsenic detected in the urine.

TOXIC JAUNDICE, WITH ATROPHY OF LIVER, FOLLOWED BY REGENERATION AND RECOVERY.

By BARBARA G. R. CRAWFORD, M.B., CH.B.

DURING the summer of 1917 I had the opportunity of seeing and treating three cases of toxic jaundice caused by trinitrotoluene. In all three there was profound illness, with jaundice, delirium, and marked diminution of liver area, and later recovery, with replacement of liver substance and function. During the course of the disease the patients were seen by one of H.M. Medical Inspectors of Factories, who confirmed the diagnosis and the diminished liver area in two of the cases (the third case, being convalescent at the date of his visit, was not fully examined), and who stated that in his opinion a fatal issue was to be expected.

The patients were workers on T.N.T. manufacturing processes, and were exposed both to fume and skin contact. C. B., male, aged 29, worked for four months in a corrugated iron building where the T.N.T. was washed, and then for eight weeks in the open air recovering T.N.T. from waste water gullies. T. M., male, aged 22, worked for three months in the T.N.T. process, and then for five weeks on the outside laundries (as the gullies are called) at the same work as C. B. B. C., female, aged 19, worked for six weeks in the T.N.T. packing house. One patient had thus been in contact with the T.N.T. for six months, and one for four months; both of these had been employed in the open air for many weeks before the onset of illness; the third had worked in T.N.T. for six weeks only, and had been free from contact for thirty-eight days before the jaundice was observed; during that time she had been attended by her own private doctor for "sore throat." The hands of all three were stained orange yellow, as is common among T.N.T. workers.

In each case the health had not been satisfactory for some weeks before the onset of jaundice, the complaints varied greatly and can hardly be regarded as definite prodromal symptoms: B. C. complained of sore throat, T. M. of faintness, C. B. of tightness of chest (and a fourth case, referred to later, of weakness of the eyes).

On investigation, however, it was ascertained in each case that the worker had felt weak, with poor appetite, slight nausea, and a tendency to headache (one case, C. B., came to the surgery asking for his discharge, as he did not feel able for his work). Cyanosis was not observed in any of these cases, and the patients had never suffered from T.N.T. dermatitis.

The first definite sign was yellowness of the conjunctivae, quickly followed by general icterus; at the beginning the patient did not appear to be seriously ill, but shortly afterwards became suddenly worse with vomiting, delirium, incontinence of urine and faeces; rigors were frequent and were associated with severe epigastric and hepatic pain; the stools were paler than normal but never entirely clay-coloured; the urine was heavily bile-stained, normal in quantity and specific gravity, acid in reaction, and containing small traces of blood and albumin (in one case tube casts and epithelial debris were present); leucin, tyrosin, and T.N.T. were absent.

In all three cases the disease ran a similar course, the patient becoming steadily worse; the liver area decreased and drowsiness and delirium persisted. In one case the patient was more or less unconscious for over three weeks, passing his evacuations under him and having to be fed by hand. In this case an inexperienced nurse placed the clinical thermometer in the patient's mouth, and a moment later recovered part of it with difficulty, the lower end having been bitten off and swallowed by the semi-conscious

man. Fortunately the thermometer end was passed later with a globule of liquid mercury in the stools.

Extreme emaciation occurred in two of the cases, the third lost weight but did not emaciate to the same extent as the others. The temperature was normal as a rule, rising occasionally for a day or less at a time to 100° F.; the pulse-rate was normal though feeble at the height of the illness. The breath was foul and had a characteristic odour; the tongue and lips were furred and bled slightly; the colour of conjunctivae and skin became dark yellow; small raised petechial spots appeared on the limbs, chest, and face; there was no itching. Vomiting was troublesome and the bowels tended to be costive; in response to an enema or an aperient slimy pale stools were passed which stained the draw-sheet pink round the edges of the soiled area; during this time no T.N.T. could be detected in the urine. Perspiration was scanty, the skin being harsh and dry.

Whenever the patient was sufficiently conscious he complained of constant pain over the liver region, and the liver dullness steadily diminished until in the two most severe cases one to one and a half inches or less could be made out in the nipple line.

The treatment was necessarily somewhat empirical, the symptoms being alleviated as far as possible as they arose. The skin was encouraged to act, the bowels kept free by a mild aperient (white mixture) and enemata; nourishment was given in small quantities at frequent intervals—milk and soda water, meat juice, thin broths, barley water, etc.; meat extracts were well tolerated, while fruit and fruit juices disagreed and caused vomiting. Injections of 6 oz. of a saturated solution of sodium bicarbonate were given by the rectum twice daily at the height of the illness, and the same salt by mouth also in a mixture and in milk to the amount of 2 drachms daily; whenever this was discontinued the patients became worse. All three cases slowly rallied, and in the fifth or sixth week of the illness began definitely to improve; delirium ceased, the vomiting and pain became less frequent, appetite better, colour less deeply jaundiced, and the stools became normal in colour and consistence; the area of the liver increased, and its function returned with remarkable rapidity; in one case (C. B.) in five weeks the liver dullness from being less than one inch increased to two and a half inches.

Convalescence, however, was slow and slight relapses frequent, the patient becoming drowsy and sick, and having recurrence of epigastric pain if allowed to do much at first, or if excited by friends or visitors. When the patients were allowed up oedema of the legs and to a less extent of the body was troublesome, and persisted for weeks after the urine was clear of albumin; the jaundice was slow in subsiding, a yellow tinge remaining after ten weeks. The liver dullness, after having almost disappeared in two of the cases and having greatly diminished in the third, returned practically to normal. The petechial spots persisted as small raised papules, with no itching, especially on the face, long after the patients had otherwise recovered and the jaundice had completely disappeared.

The three cases were eventually discharged home and returned to work, T. M. as a miner, C. B. as a sanitary worker, and B. C. on the factory traffic gang. The length of treatment in hospital averaged ten weeks, and the duration of illness until the patient was fit for work again was nearly twice that period. I have recently heard from the patients, and all report themselves well and at work at the present time, six months after recovery. In the third case, B. C., which was the least severe, blood examination revealed no pathological change, cell and haemoglobin ratios being normal. Menstruation was missed for three periods during her illness, but has occurred normally since.

In a fourth case, a girl of 18 years, who worked for four months on the outside laundries, and was seen on several occasions but not treated by me, the symptoms and course were the same—full recovery and regeneration of the liver taking place after a serious and prolonged illness of many months, in which the liver area diminished to less than half its normal size. In this case also sodium bicarbonate was given freely throughout.

The chief points of interest appear to be: (1) The regeneration of the liver after very extensive destruction. (2) The beneficial result of the exhibition of sodium bicarbonate¹ in what seemed to be hopeless cases. (3) The absence of T.N.T. in the urine when it was being excreted by the bowel.

From a series of several hundred examinations of the urine my experience has been that T.N.T. is normally present (Webster's test) when a worker is in contact with this substance, and that instead of this being a danger signal, as has been held, it is on the contrary normal and quite compatible with good health; it is not found in the urine of patients suffering from toxic jaundice.

¹ Sodium bicarbonate is recommended by Dr. W. H. Willcox for the treatment of toxic jaundice due to tetrachlorethane, BRITISH MEDICAL JOURNAL, February 26th, 1916.

ACUTE METATARSAL OVERSTRAIN (FOOT-SWELLING).

By A. ROCYN JONES, M.B., B.S., M.R.C.S.,

ACTING SURGEON AND SURGICAL REGISTRAR, ROYAL NATIONAL ORTHOPAEDIC HOSPITAL.

ACUTE overstraining of the metatarsals is one of the disabilities to which the marching foot is subject, and even before the war was being increasingly recognized by the military surgeons of the large conscript armies of the Continent as a lesion to which their recruits were liable. The complaint was first described in 1855 by Breithaupt, who gave it the name of "foot-swelling," and attributed it to injury of the metatarso-phalangeal joints and tendinous sheaths. This was the accepted explanation until 1887, when the French surgeon Pauzat, in a very striking paper, suggested periostitis of the metatarsal bones as a cause. Pauzat's explanation still holds good for some cases, but with the advent of *x* rays in 1897 fracture was revealed, and in the *Revue d'Orthopédie* of September, 1898, there is an excellent skiagram by Mannoury of Chartres, showing fracture of the third metatarsal with characteristic callus formation.

The following case illustrates the typical signs and symptoms of overstrain:

W. T., aged 28, entered the army in October, 1914. During his training in England he frequently fell out on the march because of sore feet, but was never completely off duty for this trouble. On May 24th, 1916, he was sent to France, and remained a few days at a rest camp. On May 28th he marched six miles, and at the end began to feel pain in the left foot. Next day he marched another ten miles, after which the foot, being swollen, was bandaged. The following day he again marched a few miles, and both feet became swollen and painful. He was sent to a field ambulance, and thence down the line. He was admitted to the Royal National Orthopaedic Hospital on June 15th, bearing a card with the provisional diagnosis of trench feet.

The feet were swollen, and he complained of pain across the anterior part of the dorsum of each foot, particularly the left. He had distinct *pes planus*, but, owing to the pain, he objected to any attempt at manual inversion. He was kept in bed and the feet were massaged. At the end of ten days he was allowed up; there was a recurrence of the pain, which he persisted in

Right.

Left.

An outline drawing of a skiagram showing the three inner metatarsals of a soldier's feet. There is a marching fracture of each second metatarsal with characteristic callus formation.

localizing at the anterior part of each foot. An *x*-ray picture, an outline drawing from which is here reproduced, showed a fracture of each second metatarsal bone just behind the head, with considerable surrounding callus, that on the left being the more exuberant and therefore possibly explaining the greater tenderness on this side. The patient was kept off his feet completely for one month, and during this time was given massage and hot air. He was then by easy stages allowed to get up, and six weeks after admission he could walk with comfort. To prevent relapse it was thought advisable to add a transverse

"football" bar across the sole of each boot, well behind the position occupied by the heads of the metatarsals, to take the weight for the time being off these heads, and for the planus a valgus wedge and prolonged heel were added. He was then transferred to a convalescent hospital.

It is very seldom that marching fractures occur in both feet as in this case. Of 575 cases collected by Nion in two only were both the second metatarsals affected, in one both the third, and in one the second and third. Rarely are there two fractures in the same foot; in the same series four times only were the second and third metatarsals broken and once the second and fourth. Acute metatarsal overstrain is practically confined to the three middle metatarsals. I can find no recorded instance of fracture of the first metatarsal due to marching, and fractures of the fifth are commonly the result of accident due to sudden throwing of the body weight upon the inverted foot. Usually one foot only is affected and usually only one bone; Nion gives the proportions of 112:98:17 for the second, third, and fourth metatarsals respectively. That some bones are more frequently involved than others is due to their anatomical disposition and the relative parts they play in bearing the body weight. The great diversity in the strength and projection of the metatarsal bones is readily apparent on examination of a large number of skiagrams. It seems that the head of the fifth always projects least and the fourth next, but that the projection of the heads of the three inner bones is subject to much variation. The third head may reach the same level as, but never exceeds, that of the second, and either or both of these bones may extend beyond or fall short of the first. The second metatarsal bone is more subject to variation than any other; it may be the strongest, next to the first metatarsal, or it may be the weakest. On the other hand, the third metatarsal is always a weak bone. The metatarsals as a whole are so arranged as to complete the anterior portions of the longitudinal and transverse arches of the foot, the second and third occupying the highest plane. At their bases they all unite with the tarsus, but the first has the widest range of movement, the fifth next, and the fourth next, whereas with the second and third, as Hepburn points out, "an extremely powerful interlocking of parts is provided which places any marked independent movement of these metatarsal bones entirely out of the question." Again, in the *x*-ray picture of a normal foot it will be seen that the second and third metatarsals are practically parallel, and run in a strictly antero-posterior direction, whereas the others radiate obliquely forward.

This disposition of the bones provides for the transmission of the body weight by the astragalus along a line passing through the second metatarsal head.

When standing the weight is borne by the two feet, the chief points of support in each foot being the os calcis, the shaft and head of the fifth metatarsal, and the head of the first metatarsal. During ordinary walking, however, the main points of contact with the ground are continually changing. First the heel is brought down, then the sole, and then the body is levered forward on the metatarsal heads. During this last part of the step the four inner metatarsals and their toes are the chief points of contact, with the second and third forming the most direct anterior supports of the longitudinal arch of the foot, and consequently subject to very direct pressure. That this is so is shown by the boots of people with normal feet, from which it appears that the sole is most worn about the middle, at a point corresponding with the heads of the second and third metatarsal bones. Frequently there is also a callosity in the corresponding position on the sole of the foot. It is during the successive weighting of the metatarsal heads that overstrain is produced. The feet of the vast majority of recruits quickly accommodate themselves to the rigours of route marching, but occasionally there is a breakdown, either in the direction of flat-foot or metatarsal overstrain, or both. In these the extra loading due to the pack, the fatigue induced in the small muscles of the foot, and the roughness of the ground traversed are cardinal causes. With every unevenness of the ground the sole of the boot becomes slanting, and the tendency is for the mid-metatarsus to become more heavily weighted, and occasionally one bone more burdened than the others. This is further promoted by the lessened co-ordination between the metatarsal bones as the result of tired muscles and the generally diminished sensibility of the foot induced

by fatigue. The frequency of fracture of the second and third metatarsals is due to their commonly slender length, their fixity, their direct forward projection, their lie in the transmission line of body weight, and the part they play in the leverage action of the foot. The fourth is less often affected because it is more mobile, and subject to less direct stress; the first escapes because of its strength and mobility, while the fifth, which is fairly strong and mobile, likewise escapes because it is the least strained during the forward lifting of the body.

In the diagnosis it should be remembered that the usual history given is that the symptoms developed gradually during a march, and that rarely is there any account of the accident. The pain is localized to the metatarsus, and by running the fingers along the bony shafts a very sensitive spot will be found in one of them. If a fracture occurs discoloration of the skin due to extravasation of blood may be present, and possibly crepitus elicited. Swelling of the foot is usually a prominent feature, whence the name "foot-swelling," given to the complaint when its pathology was still uncertain. The diagnosis can only be definitely established by the *x* rays. A skiagram may show a fracture and possibly even callus formation, the break generally being in the anterior half of the shaft. If there be no fracture, periostitis may be present, shown by vagueness or irregularity of outline, or swelling of the shaft of the bone. In this connexion it is interesting to note that Momburg found in some old-standing cases definite spindle-shaped thickenings of the shaft of a metatarsal, and he also notes thickening of the compact bone at the expense of the cancellous tissue by a process of osteo-sclerosis. These osseous thickenings may occur by way of compensatory adaptation in the feet of soldiers who have never complained of any symptoms or of any unusual difficulty in marching. It may be mentioned that statistics show that troops drawn from mountainous districts suffer less from metatarsal overstrain than those from the lowlands, for hill climbing tends to strengthen the metatarsus and pedal muscles, and possibly to promote a better power in dorsiflexing the foot. This climbing influence is best seen in Alpine guides, who usually have an extreme range of movement at the ankle-joints.

The broad lines of treatment have already been given in the case quoted—that is, complete rest off the feet for four weeks and the application of massage and hot air. The heating chamber should be at a temperature of 300° F., and the limb well protected by wool and flannel bandages; the treatment should occupy from thirty to forty minutes daily. As an alternative treatment passive hyperaemia may be adopted. A Martin's bandage is applied around the leg just above the ankle, so as partly to obstruct the venous flow from the foot. The bandage should be arranged so as to cause no discomfort, and the foot must feel warm during the whole sitting. This treatment should be applied at first for an hour daily and gradually extended to several hours; at Spandau it is even persisted in for twelve hours continuously.

At the end of one month, or less in the case of periostitis, the patient is allowed to get on his feet gradually. Ten days after this, if there is no pain and no swelling, he is allowed to walk freely. In the case of fracture, the transverse "football" bar, referred to above, is worn for a few weeks, and may then be discarded. Care should be taken that a properly fitting boot is provided. The present army boot is a fairly good shape and it has to be strong, but one sometimes sees, after much wear, either a distorted upper or a "rocker" sole—that is, a sole which is extremely convex from front to back. These faults, which interfere with the proper play of the toes, are easily remedied by stretching and straightening the shoe on a last.

I am indebted to Dr. R. L. Rawlinson for enabling me to examine a large number of skiagrams.

THE VALUE OF AMYL NITRITE INHALATIONS IN THE DIAGNOSIS OF MITRAL STENOSIS.

By R. A. MORISON, M.D., LIEUT. M.R.C., U.S.ARMY.
(From the Military Heart Hospital, Colchester.)*

MITRAL STENOSIS develops insidiously and symptoms of a really incapacitating nature are frequently absent until the lesion is well advanced. In soldiers it is often discovered accidentally during the routine examination of a man reporting sick for a trivial complaint. In young soldiers, when very early and uncomplicated, it is unaccompanied by subjective symptoms which characterize the state.† The number of border-line cases seen appears to be remarkable, until it is remembered that the strains to which the men are subjected are precisely those calculated to call forth symptoms in early cases. Advanced mitral stenosis has been largely kept out or sorted out of the army, and patients who suffer from "irritable heart" in the absence of structural change very frequently present such signs as accentuation of the first heart sound, accentuation or reduplication of the second heart sound, signs which are credited with significance in the early diagnosis of mitral stenosis. In dealing with military patients a clear decision is most desirable; it is imperative when, in sorting cases bearing cardio-vascular diagnosis, tolerance of exercise is largely relied upon.‡ Men with structural heart disease are to be guarded against over-exertion. We may take a diastolic (presystolic) rumble or thrill, or both, to be the most positive and convincing sign of mitral stenosis, and it is at present inadvisable to diagnose this lesion in the absence of such a murmur. Any method, therefore, which accentuates such a murmur, or discovers it, must be of considerable value.

Amongst patients who fall near the diagnostic border-line (a border-line which it should be clearly understood varies according to the skill, experience, and opinion of the observer) there are a number of patients who present no suggestion of mitral stenosis when they are examined standing, but who present unequivocal signs while lying down; there are a number who present inconclusive signs of stenosis while standing, but signs of stenosis become clear on lying; still a further number who exhibit no conclusive signs standing or lying, but in whom the diagnosis is no longer in doubt while they lie after exercise. At the Military Heart Hospital at Colchester all cases are auscultated standing and lying, and lying after exercise, and a considerable number of presystolic murmurs are detected which would otherwise escape observation.

Amyl nitrite is used as a further test in doubtful cases; its action, like that of exercise, is to increase the flow of blood through the A-V ring, a change which favours the production of the murmurs in question. We desire to give our early impressions of the experience with amyl nitrite. The observations are not based upon *post-mortem* evidence, but upon the assumption that a clear presystolic murmur signifies stenosis in the absence of aortic disease. On that assumption, it is clear to us that amyl nitrite will often bring to light a clear presystolic or full diastolic murmur in a patient lying on his back, who had exhibited no murmur previously, and will thereby render an early mitral stenosis diagnosable.

In twelve cases in which presystolic murmurs were suspected, but in which they could not be recognized with any degree of certainty, amyl nitrite (inhaled from a 3 minim capsule until a reaction was evident) brought forth unmistakable murmurs in six instances. Amongst the first signs of early mitral stenosis is an accentuated first sound; from this sign the sounds pass to a simple reduplication with accentuation; to perhaps a triplication, and thence to what may, or may not, be termed a murmur, according to the idiosyncrasies of the examiner.

The point which is to be emphasized is that amyl nitrite, in a large proportion of cases, will raise the scale of the signs, bringing them nearer to a point where a diagnosis becomes certain.

* Observations undertaken on behalf of the Medical Research Committee.

† The actual proportion of clearly diagnosable mitral stenosis amongst such patients is approximately 4 per cent.

‡ It is inadvisable that the exercise tolerance tests should be applied in mitral stenosis, and those who suffer from this lesion are to be sifted out.

As to the cases in which amyl nitrite has the reverse effect, and produces a lowering of the scale, in some cases abolishing a diastolic murmur, we speak with more diffidence, yet it is extremely suggestive that this reversal of the usual effect has been witnessed for the most part in cases in which aortic regurgitation was undoubtedly present, and where consequently the murmur may have owed its origin to a different cause (Flint murmur).^{*} Whether it will prove ultimately that the test serves to differentiate the Flint murmur remains for the future to decide; so far as military diagnosis is concerned, it is a point of lesser importance; the point for which publicity is desired is the usefulness of the drug in bringing out clear presystolic murmurs in cases in which mitral stenosis is suspected but not proved.

A PYLON, OR TEMPORARY ARTIFICIAL LEG.

BY

W. H. BROAD, M.D., CAPTAIN R.A.M.C.,
MILITARY ORTHOPAEDIC HOSPITAL, ALDER HEY, LIVERPOOL.

AFTER amputation through the thigh or leg there is, as is well known, progressive diminution in the girth of the stump, owing to muscular wasting; consequently the "bucket" of an artificial leg, which fits accurately at the time of fixing, will in a few weeks become loose.

FIG. 1.—Plaster cast of stump (hollow).

It occurred to me that the bucket for a temporary leg might be made of papiermâché, which could be broken up and replaced or remoulded, if necessary, periodically, until the stump reached its minimal circumference.

It was believed also that by arranging for the end of the stump to be subjected to graduated pressure by padding the floor of the bucket, the weight-bearing power of the stump would be improved.

The main principles of the leg were explained to Mr. J. D. Danson, technical instructor in the curative workshops, Alder Hey, and as a result of his expert advice and experiments the temporary artificial leg here described was made.

An accurate cast of the stump, up to a height of 15 in., if available, is taken in plaster-of-Paris (Fig. 1); on to this plaster cast a layer of soft felt is sewn (Fig. 2); this in turn is covered with a layer of papiermâché, about $\frac{1}{8}$ in. thick. (The papiermâché is made by boiling in water disused tram tickets, paper, etc., straining, and mixing

FIG. 2.—Cast covered with felt and papiermâché.

FIG. 3.—Metal rods which support the papiermâché.

with whiting and gluc.) A wooden base is fitted to the floor of the bucket thus formed, the paper bucket is then reinforced by four light metal bars, which are welded at their lower ends into a tube, into which is fitted the wooden peg (Fig. 3). If the bucket is made to fit a stump below

^{*} Thus out of ten cases of aortic disease in which a presystolic or diastolic rumble was audible at the apex, suggesting stenosis, the murmur cleared entirely under amyl nitrite in five instances.

the knee, the leg has a hinge-joint at the knee, to allow either a partial or complete range of movement at that joint (Fig. 5).

The leg provides an accurately-fitting bucket for the stump. It can be fitted as soon as the stump is healed, and

FIG. 4.—Complete pylon (for thigh stump).

FIG. 5.—Pylon for leg with knee hinge.

the use of crutches and the consequent risk of crutch-palsy obviated. The leg is not to be too light, so that the muscles may receive adequate training. The patient is early familiarized with the wearing of a bucket and also with the gradual transmission of his weight to the end of the stump; he can regulate the pressure by adjusting the thickness of the pad at the bottom of the bucket. The cheapness of the material permits of the renewal or remoulding of the bucket at a trifling cost.

MEDICAL, SURGICAL, OBSTETRICAL.

THE FARADIC CURRENT FOR THE IDENTIFICATION OF MUSCLES DURING OPERATION.

IN certain operations difficulty may be experienced when searching for structures which lie between separate muscles; for instance, in ligaturing the ulnar, radial, or anterior tibial arteries or in dealing with their corresponding nerves. Such operations are more common than usual now in consequence of war injuries, and the difficulty in defining the limits of two adjoining muscles is increased by scar tissue which naturally lies in the line of the operation.

Such operation can be much simplified by the use of the faradic current. This may be applied locally to the surface of one or other muscle before the fascia is divided or even before the skin incision is made, or it may be applied to the nerve above the field of operation if the muscles have a separate nerve supply. The current may be applied so as to give a series of twitches or the muscle may be kept in a state of contraction as long as is needed. Not only does this show the limits of each muscle, but it also makes the separation of the muscles easier if one is kept contracted while the other remains flaccid.

I recently had the opportunity of using this method in a case of bullet wound of the middle of the forearm in which the subsequently formed scar tissue had involved the ulnar nerve, causing typical ulnar paralysis and anaesthesia. On cutting down to the fascia in the line of the nerve no distinction could be made out between the flexor carpi ulnaris and the flexor sublimis digitorum; these muscles were also bound together by scar tissue. On applying the electrode to the ulnar nerve behind the elbow the flexor carpi ulnaris was at once defined, and, after the fascia was divided, there was no difficulty in

separating this muscle from the flexor sublimis digitorum, and the nerve was found and cleared from the scar which was compressing it.

All that is required is a small coil with battery and something to use as a sterile electrode in case it is wanted to stimulate the surface of muscle; the ordinary electrode suffices if the nerve is to be stimulated. Only a weak current is needed.

T. H. FOULKES, M.R.C.P., F.R.O.S.,
Lieut. Colonel I.M.S.

THE EFFECTS OF ELECTRIC ARC WELDING UPON THE EYES AND SKIN.

My attention was first drawn by a tramway engineer to certain effects upon the eyes and skin produced by electric arc welding. He was using the process for welding broken rails *in situ* to save labour and time. The mechanical results were excellent, but he noticed that the workmen, himself, and visitors who came to see the process were affected adversely. Briefly, the symptoms were intense lacrymation and eye tenderness. "The eyes felt as if the lids had been sandpapered." The conjunctivae were much injected. The symptoms did not come on until some hours after exposure, or until the eyes were closed. With repeated exposures the eyes appeared to become accustomed to the light. Reddening of the skin exposed, followed by smarting and peeling, also were noticed. With repeated exposure the skin became "sunburnt."

On my visit I noticed (1) that the light was intensely strong and white; (2) that a considerable amount of gas, smelling like ozone, was generated; (3) that much very fine carbon dust was blown about; (4) that the heat was great. An x-ray plate, enclosed in two light-proof envelopes, was fogged evenly all over, in spite of lead discs closely held by clips against it.

The cause of the conjunctivitis seems to be the intense light, and not dust, as the eyes were protected by glass. The presence of ultra-violet or N rays I do not think probable. Some form of secondary ray may be given off by the molten metal, but of this I am not competent to judge. The matter appears worthy of full investigation.

Southampton.

OSCAR HOLDEN, M.D.

ACUTE YELLOW ATROPHY IN SYPHILIS.

I READ with deep interest in the BRITISH MEDICAL JOURNAL of January 19th a paper on this subject by Professor Stuart McDonald.

As I have been in France for the last three years my notes are not at hand, but I would like to mention a very important fact regarding his suggestion "that acute yellow atrophy may result as a direct consequence of treatment by 'salvarsan' preparations." As Professor McDonald says, acute yellow atrophy is one of the rarest diseases to be met with in medicine, a statement with which all physicians will agree. I have personally conducted over 6,000 *post-mortem* examinations in a hospital and asylum experience in the last thirty years, and I have only met with seven cases of acute yellow atrophy, all of which have been recorded. In all these cases there was a definite history of recent syphilitic infection, and in only two of them had there been any mercurial treatment. All the cases occurred in adults between the ages of 20 and 43, four being males and three females.

Whatever the exact etiology of this fatal disease may prove to be, it seems certain that syphilis plays the most important part, but I cannot see any justification at present for associating it in any way with treatment by salvarsan—by far the best means we have to-day for the treatment of recent infections—and I am sure that Professor McDonald does not wish to convey that impression.

NATHAN RAW, C.M.G., M.D.,
Senior Physician, Liverpool Hospital, France.

"IRRITABLE HEART."

My experience of the class of cases discussed by Dr. Lewis (p. 363) was gained at a Mediterranean station, where we dealt with the men in an earlier and less selected state than that in which they would come under his care. Here we had gathered together all the cases classed as D.A.H.

out of a big camp. Most had served at Salonica, Gallipoli, or Egypt. Very many had had malaria.

After careful examination they were all collected in separate marquees and placed under a physical instructor, and each morning were given gentle physical exercise for a period of ten minutes, the pulse, respiration, and temperature having previously been taken. At first the medical officer in charge of the cases was present during the entire period of drill, and made careful notes of any cases which did not seem to stand it well. After drill the men lay down for at least ten minutes; the pulse and respiration were taken first after the exercise, and again after three minutes' rest. After seven days' training in milder exercises the whole squad was examined, and those who regained their normal respiration and pulse after three minutes' rest were promoted to more complicated exercises. After a further week those who were improving were made to do a combined exercise for double time.

Thus three classes were kept going, and at least once a week the medical officer examined every case carefully to ascertain if he were fit for the longer and more severe exercise. I also gave the men an extra ration of sugar, which appears to have a synergizing effect on the cardiac muscle.

To summarize results, we found after treatment:

1. 70 to 90 per cent. of the cases labelled "D.A.H." were fit for at least light duty, and of these 20 to 30 per cent. were fit for ordinary duty.

2. A very large proportion of all the cases were fit for ordinary base duties.

3. The only real practical test of the fitness for duty of a man labelled "D.A.H." is the time in which, after a given exertion, he regains his normal pulse and respiration rate. If this be under three minutes he may be regarded as fit for at least light duty.

4. Mere rapidity of pulse may be ignored as of no necessary pathological significance.

5. Many of the cases called "D.A.H." are due to excessive thyroid activity, and not to any cardiogenic conditions. The drill or gymnastic treatment seems to point to this, for it invariably aggravates this condition. It does not follow they are unfit for duty.

6. Ordinary treatment of D.A.H. cases in ordinary hospitals, after, perhaps, a couple of weeks' rest in bed, is not merely useless, but harmful, unless some form of gymnastic exercise be added.

J. C. McWALTER, M.B., F.R.F.P. and S.Glasg.

GALYL IN MALTA FEVER.

So far as I know, the treatment of Malta fever by galyl or salvarsan has not yet been recorded. The two following cases are therefore worth reporting:

CASE I.—A strong healthy man, aged about 35, in easy circumstances, with a comfortable home and perfectly sanitary surroundings, and not overworked, had suffered for about four years from attacks of fever at varying intervals; occasionally the interval was three months, but often as little as one month. The fever usually reached 102° F., but sometimes even 104°. Though Malta fever was suspected early in the course of the case, blood tests made by several bacteriologists did not confirm this suspicion, and only after about two years was a positive Malta fever reaction obtained. Inoculation with sensitized Malta fever vaccine was then carried out most conscientiously for more than a year. At times the inoculation seemed to be helping, but progress was very slow and uncertain.

About October, 1916, severe attacks began again in spite of the inoculation, and returned every month. The patient had lost a serious amount of weight, was weak and languid, and felt hardly able to conduct his business. On January 6th, 1917, I gave him an intravenous injection of 0.3 gram of galyl dissolved in 3 ounces of freshly distilled water. Since then there has been no return of fever, the lost weight, strength, and energy have all been regained, and the patient is to-day, ten months after the injection, in perfect health.

CASE II.—An elderly hard-working man consulted me for intractable lumbago and sciatica of about nine months' duration. His local doctor had diagnosed Malta fever, and had treated him with many drugs but without avail. A blood test confirmed the diagnosis. On July 4th, 1917, I gave him 0.3 gram galyl intravenously, and he returned home two days after. When next I saw him, early in October, he told me the treatment had been a great success, all his pain had disappeared within a few days, and he was soon able to walk about and do his work as usual.

A line of treatment cannot be based upon two cases, but the results in these are sufficiently striking to suggest that salvarsan or galyl should take a prominent place in

the treatment of Malta fever. Case 1 is especially noteworthy, for in spite of the very favourable conditions under which the patient lived, and in spite of frequent and prolonged holidays at the coast (the oldest Kimberley remedy for "camp fever," a good percentage of which we now believe to have been Malta fever), he was no whit better at the end of four years, and the effect of the galy was immediate, and so far seems to have been permanent. Any one has had to deal with Malta fever will realize what an immense help a remedy which acts quickly, and gives a permanent cure, would be in this tedious disease, so aptly called "sluipende koors" (sneaking fever) by the Dutch farmers.

E. OLIVER ASHE, M.D.Lond., F.R.C.S.Eng.,
Surgeon to Kimberley Hospital.

Reports of Societies.

HYPOTONIA AND TROPHIC CHANGES.

At a meeting of the Section of Neurology of the Royal Society of Medicine, on January 24th, Captain GEORGE RIMMOEN contributed a paper on muscular hypotonia and changes in nutrition associated with lesions of the posterior columns of the spinal cord and the posterior roots. Defining reflex muscular tone as postural contraction (Sherrington), he pointed out that tonus was found in those muscles which maintained the animal erect; it depended upon a reflex system excited by afferent impulses arising during tension and stress from muscles and tendons. The controlling centres of this system were situated in the mid-brain, pons and medulla. The activities of this system were adjusted through impulses from the labyrinth and by the cerebellum. The peripheral fibres ran in the deep muscular nerves. Hughlings Jackson taught that rigidity of the affected limbs in cases of hemiplegia was due to unantagonized cerebellar influences. The activities of this reflex mechanism might be entirely unconscious. Head and Thompson stated and emphasized that "sensation may never be evoked until some disturbance of equilibrium produces impulses which, passing up sensory paths, reach the highest centres concerned with sensation." Their findings suggested the close association through collaterals of the posterior columns and the afferent cerebellar tracts. Whenever hypotonia followed lesions of the posterior columns, it was always associated with defective appreciation of space; but in hypotonia resulting from lesions of the posterior roots, at a level where all sensory impulses were still in their primary grouping, all aspects of sensation were affected, and the area of sensory loss was determined by the number of the roots involved. Captain Kiddoch quoted instances of cases to show that by an investigation of the condition of sensation in the affected parts the level and the extent of the lesion giving rise to the hypotonia could usually be determined. He described some of the trophic and vasomotor changes frequently observed in the affected hands after injury to the posterior columns of the spinal cord in the region of the cervical enlargement; in character these changes closely resembled the associated trophic and vasomotor changes found in cases of causalgia of the median nerve. From the sensory picture of the hands he adduced that trophic and vasomotor changes of this type were due to damage to the posterior roots involving the "visceral" afferent sympathetic fibres belonging to the sympathetic nervous supply of the hand, and not to any injury of the spinal cord. The afferent fibres of the sympathetic involuntary nervous system probably had more or less the same regional distribution as the efferent fibres, and passed into the spinal cord by the segmentally corresponding posterior nerve roots. Such facts might explain the minimal nutritional and vasomotor changes in the legs and feet after injury to the lower lumbar and sacral posterior nerve roots, where hypotonia was present and sensation was definitely affected but not completely abolished.

TRINITROTOLUENE POISONING.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, held on April 12th, the President (Dr. G. S. BUCHANAN) in the chair, Dr. W. J. O'DONOVAN (Chief Medical Officer, Welfare

and Health Section, Ministry of Munitions) read a paper on the epidemiology of trinitrotoluene poisoning, which was in effect a continuation of a chapter in preventive medicine begun at a meeting of the society in January, 1917. Dermatitis, gastritis, and toxic jaundice produced by T.N.T. were described, and stress was laid on the necessity of regarding all cases of purpura or of uterine bleeding with the gravest suspicion, as these symptoms might represent the onset of aplastic anaemia. Thirteen cases of these grave anaemias were known to have occurred and only one was alive. Toxic jaundice was now rare and the death-rate had fallen considerably. In stamping out toxic jaundice, and with it the large amount of minor illness due to T.N.T., the co-operation of the engineers was invaluable. Clean working was the cardinal rule, and automatic working was the only way of securing this with thousands of unskilled female workers. The various processes in which T.N.T. absorption might occur were illustrated by photographs, and the various types of automatic machinery that had largely helped to eliminate hand contact were shown in the same way. Casein varnish had not proved a success in practice; respirators were of little or no service, and the use of gloves, except for hot or rough work, was discouraged; workers could not keep the interior of gloves free from T.N.T., and a poultice of T.N.T. on a hot hand was the ideal way to secure absorption. Attention was drawn to the variability of the incidence of the effects of T.N.T. at the same factory; this suggested that the pathological ill effects might be coincident, but were not necessarily dependent on one another. The way in which factories were separately attacked after periods of freedom and the absence of fresh cases under constant working conditions suggested that two factors came into play—first, the toxic effect of T.N.T., and secondly, possibly portal infection. The work of Opie on the production of experimental cirrhosis of the liver in animals, and a recent paper by Dr. Stuart McDonald¹ on acute atrophy of the liver after the administration of salvarsan, lent support to this view, but the question remained open. Attention was drawn to a publication by the late Mr. Simeon Snell in the BRITISH MEDICAL JOURNAL of March 3rd, 1894, dealing with poisoning by dinitrobenzol, and it was shown how closely parallel were his recommendations to those of the T.N.T. Committee appointed by Dr. Addison when Minister of Munitions; it was not known, however, that any cases of neuritis or of amblyopia due to T.N.T. had occurred. The chief precautionary measures—alternation, periodic medical examination, clean working, and ventilation—were explained and detailed references were made to managerial, explosive, and wages aspects with which these points are bound up. Recognition was paid to the services of the T.N.T. factory medical officers, working continuously for months in isolated areas with none of the amenities of ordinary medical life.

The paper was discussed by Dr. LEGGE (Home Office), Dr. COLLIS (Ministry of Munitions), Lieut.-Colonel O'REILLY, R.A.M.C., Dr. CHRISTINE PILLMAN, and Dr. MACNALLY.

Reviews.

COUCHING FOR CATARACT: ITS DANGERS.

THE operation of couching for cataract is one of the most ancient procedures known to surgery, the earliest description of the method being that given by Celsus, a contemporary of Christ's. Besides its antiquity it is perhaps one of the operations which is most frequently performed for the relief of cataract, since this degeneration of the eye is so common in India, and the nature of the operation lends itself readily to the practice of wandering native practitioners. Further, it is not so long ago that the operation was practised in Western countries. For all these reasons Colonel ELLIOT's book on *The Indian Operation of Couching*¹ is of great interest, for he deals with the nature and results of the operation, particularly at the hands of untrained and often quite ignorant and primitive folk

¹ BRITISH MEDICAL JOURNAL, January 19th, 1918.

² *The Indian Operation of Couching for Cataract*; incorporating the Hunterian Lectures. By Robert Henry Elliot, M.D.Lond., Lieut.-Colonel I.M.S.(retired). London: H. K. Lewis. 1917. (Roy. 8vo, pp. 94; 45 figures. 7s. 6d. net.)

whose only knowledge is that gained through the handing down of an old tradition.

Colonel Elliot has divided his book into sections dealing with the history of couching, the technique of the operation, and the Andian coucher and his habits; there is a chapter on statistics of observed results, one on the pathological anatomy of couched eyes, and, lastly, chapters on the diagnosis and clinical symptoms. In each he has done full justice to his subject, and he is to be congratulated on the facility with which he introduces his reader into a lively association with his work and experience in the East. One of the difficulties of an investigator is illustrated by his statement that he had never been able to see a coucher at work during his twenty-five years in India, yet his knowledge of the results of the operations of these men was direct enough in his hospital work.

The charm of the operation to the uninitiated lies in two facts: it is very easy to perform, and the results obtained are immediate. The hand is passed over the eye, and lo! the blind man sees. The needle or thorn is thrust suddenly through the cornea or sclera of the eye, according to whether the anterior or posterior operation is performed, so as to penetrate the lens; and in the same movement with a turn of the wrist the lens is thrust down into the posterior chamber of the eye and the pupil is clear. Dirt and injury due to clumsiness account for a vast number of speedy losses of sight. But even with the best of immediate results there is the steadily approaching Nemesis of total and irretrievable blindness, owing to the dislocated lens acting as a foreign body within the eye and setting up chronic cyclitis. A summary of the Hunterian Lectures given by Colonel Elliot last year was published in our columns at the time (1917, vol. i, p. 334), but in this book the full story is told, and the moral is drawn. Cataract in India strikes down a man at maturity, when his life's work is beginning to have its full effect, and the operations of the quack destroy his one chance of recovery. Prohibition might be desired, but, as the author says, the people are not ready for it. But there should be (1) the systematic dissemination of knowledge through Government agencies amongst the people; (2) the improvement of ophthalmic education. A movement in these two directions is already on foot, and in time will bear much fruit.

THE FUTURE OF THE MEDICAL PROFESSION UNDER A NATIONAL HEALTH MINISTRY.

A MEETING of the Fellows of the Royal Society of Medicine was held on April 15th, Sir RICKMAN GODLEE presiding, to discuss the future of the medical profession under a Ministry of National Health. The subject was opened by Dr. J. F. GORDON DILL, who said that a central authority to deal exclusively with all matters of national health should be established under a Minister of Cabinet rank, and to this administration the various departments now engaged upon health matters should be transferred and as far as possible fused. The secretaries and higher personnel should be qualified medical men, and there should be an administrator-general for the kingdom, national administrators for each country, and inspectors of preventive medicine and directors of clinical medicine for each division or county. The divisions should be made up of so many districts, with a medical officer allotted to each, though in suitable centres of population contiguous districts might be pooled. The district medical officer would reside in the district, be the family doctor for most of the community, and keep such records and make such returns as might be required. Consultants and specialists should be appointed to areas of suitable size and be the visiting physicians of the hospitals in those areas, and central laboratories should be established in charge of resident or visiting pathologists. Dr. Dill also discussed the terms of service of the medical officers, the responsibility of the peripheral executive to the central administration, and the desirability that, along with such a state system, no limitation should be imposed on freedom of choice, either of doctor or patient.

Sir ARTHUR NEWSHOLME said that state institutional measures for dealing with disease had grown in a remarkable manner during recent years. Of the 300,000 hospital beds (including asylum beds) in England and Wales, 170,000 were under the public health authority and 96,000

under the Poor Law authority. With this development had arisen such arrangements as school medical inspection and clinics, public treatment for tuberculosis and for venereal diseases, maternity and child welfare work, and, not least, the vast insurance service, with one and a quarter millions spent annually on maternity benefit, three-quarters of a million on sanatorium benefit, and four and two-fifths millions on the payment of medical practitioners for domiciliary attendance. Any satisfactory medical service in the future must be as readily available to the poor as to the well-to-do, not only in respect to consultation and treatment, but also in respect to laboratory facilities and skilled nursing. There must be increased collaboration between voluntary hospitals and private practitioners. There must be more team work between consultant and general practitioner and between nurse and doctor, and economy of effort might be effected by the proper utilization of less skilled persons under fully qualified supervision.

Sir BERTRAND DAWSON said that the feeling that some change was needed antedated the war. There was a growing opinion in the community that the best treatment of disease and the measures for securing health must be available to all by right and not by grace. Medicine in this respect was only repeating the history of national education. But the maintenance of health and the cure of disease were becoming increasingly complex and costly, with the result that the best treatment would be decreasingly available for the community at large; yet not only was there the demand of the public that the best treatment should be made generally available, but there was also the feeling on the part of the profession that it must give its best in all cases, and the only way out of the difficulty was some degree of state support and state control. Neither in private practice nor in hospitals would it be possible to continue altogether on the voluntary basis; every new invention, for instance, added to the expense of hospital upkeep. There were three possible forms of state aid: (1) To make the medical profession a salaried civil service. With this he could not agree. In no profession was there such a difference between the minimum and the best, between what a man could get on with and what he might do if he lived up to his ideals. That intensive effort, which at once made medicine so exhausting and so inspiring, would not be encouraged by a state-salaried service. (2) To amplify the insurance system, with its underlying principle that the sick should be partly paid for by the state and partly by the individual—at present a cumbersome method, but one which had possibilities. (3) The state endowment of fabric. Explaining what he meant by this last, Sir Bertrand Dawson said that curative and preventive medicine must come together in thought, teaching, and organization, and it was important not to multiply specialists too much or to deprive the general practitioner of the things that made his profession interesting. The general practitioner in a small township should be in charge of both the preventive and the curative treatment, and although an increased proportion of his earnings would be by salary, he would still be a free man as regarded his patients, while his local authority would give him every sort of encouragement in return for his work by providing him with a collection of buildings and equipment.

Dr. BENJAMIN MOORE pleaded for a whole-time national medical service, with local control in the various branches according to the needs of the district, and argued that there would be an even fuller choice of doctor under a whole-time service than there was at present. Dr. LAURISTON SHAW thought that consultants should confine themselves to consultative work, and that their relation to the general practitioners should be as uncompetitive and cordial as that between barristers and solicitors. Sir RICKMAN GODLEE, in closing the discussion, said that as a man at the close of his professional career, he might be expected to look askance at the rising tide of state control, but he hoped there would still remain some little bays and inlets for those who shared his own professional ideals.

SURGEON-GENERAL RUPERT BLUE, of the United States Public Health Service, has asked Congress to appropriate £60,000 to be applied in establishing a Sanitary Reserve Corps whose function it will be to combat outbreaks of disease both in time of war and in time of peace.

British Medical Journal.

SATURDAY, APRIL 20TH, 1918.

CASUALTY CLEARING STATIONS IN MOBILE WARFARE.

THE great lesson of the war with regard to the treatment of the wounded man has been that the earlier and more efficiently his wounds are dealt with surgically the more rapid, certain, and complete is his recovery. The tendency, therefore, has been to operate on an increasingly large proportion of cases at the casualty clearing stations, which as a rule provide the earliest possible stage for carrying out radical treatment. During stationary warfare the accommodation provided in these units has increased enormously, to four and even six-fold in many cases. Many of the stations had bedsteads as long ago as September, 1916—in some cases, we believe, six months earlier—and probably most of them now have a good many. We have heard of as many as 150 to 200. They are used especially in the resuscitation wards, which have often been described, and for the more seriously wounded—as, for instance, chest wounds, and fractures of the femur. The results obtained at these stations during the last year and a half or two years have more than justified this policy.

A little reflection on the experiences of the past few weeks will show how easily the trials the wounded endured might have been aggravated and their chance of recovery destroyed had the arrangements entailed delay in the treatment of wounds. It is difficult to over-estimate the saving of life and of limb which has resulted from early efficient treatment, and the real military help which can be given thereby, in that lightly wounded men have a vastly shortened convalescence. Briefly put, a lightly wounded man successfully operated on at an advanced casualty clearing station may become an active soldier again in a comparatively short time, whereas if treatment be delayed he may be of no further use to the army, and may be more or less crippled for life. The economic value of the work done at the casualty clearing stations to the army in the first instance, and afterwards to the nation as a whole, is very high.

The development of casualty clearing stations during the last year or two of almost stationary warfare has naturally followed lines which adapted them to the conditions existing, but if we are to look forward to periods of open warfare some of their arrangements will no doubt undergo modification. The original plan was that clearing hospitals, the forerunners of casualty clearing stations, should be accommodated in suitable buildings if available, or in tents. Suitable buildings have not, we believe, very often been available in recent times, and in setting up casualty clearing stations huts have sometimes been used in place of tents. Such huts required several days and many men to erect and nearly as long to dismantle, to say nothing of the difficulty involved in their transport. Huts have to be abandoned, along with other heavy impedimenta, during a rapid retreat under pressure of the enemy.

To meet a period of more mobile warfare advanced hospital units will have to be, as far as possible, correspondingly mobile, though movement may be necessary only at intervals measured by months. It would be a grave misfortune were surgical opportunities during such intervals to be curtailed in any serious

way. Very many of the operations performed in casualty clearing stations are of the most serious and difficult character conceivable, and such as a surgeon is only justified in undertaking if he can command the essential appliances of his craft. Among these is an operation room properly constructed and equipped, and capable of being kept surgically clean. It is, we believe, the general opinion of those who have had practical experience that to fulfil these conditions, should no suitable large room in a permanent building be available, a wooden structure is necessary. If enemy action enforces a move, this wooden operating room must usually be abandoned. It is apparent, therefore, that if the best surgical treatment is to be carried out at what has been found to be the best time, the casualty clearing stations cannot be made so mobile that, in the event of rapid retreat, a proportion of the equipment will not be lost.

The authorities are, therefore, faced with the alternatives that either they must sacrifice the interests of the wounded man and all that is entailed thereby or they must be prepared to lose some equipment. We know that the nation would have no hesitation in its choice between these two alternatives. We do not doubt that the medical authorities will find a way to adapt the fabric and equipment of the casualty clearing stations to the special needs, so that the very best surgical treatment shall be available as early as hitherto, while at the same time such mobility is regained for these units that only the minimum loss of material will result. Waste must always occur in war. The loss of guns does not deter the fighting man from replacing that loss with improved weapons and distributing them where they will have greatest effect.

We feel that we can safely leave these momentous decisions in the hands of those whose practical experience during this war best enables them to cope successfully with all contingencies, and that they will know how to win fresh laurels for the Royal Army Medical Corps.

THE AUTOMATIC BLADDER, MASS-REFLEX, AND OTHER PROBLEMS.

THE advance of medicine depends partly on clinical experience and largely on special investigations carried out in laboratories, both in direct relation to disease and on other lines. It is now generally recognized that pure physiological research undertaken to increase scientific knowledge, though not at once obviously applicable to the needs of medical practice, sooner or later makes the clinician its debtor. On the other hand, the work of the active physician and surgeon, though often of help in elucidating the problems of physiology, is rarely of such an exhaustive and far-reaching character as that of Dr. H. Head and Dr. G. Riddoch recorded in the current number of *Brain*.¹ Clinical research of this kind demands a special training and a devotion of time and energy that are only exceptionally available; it is therefore of peculiar value, and to some extent may redress the balance of debt to our physiological colleagues.

Utilizing the unexampled opportunities afforded by the casualties of the war for an intensive study of the phenomena of gross lesions of the spinal cord, Dr. H. Head and, under his inspiration, Dr. Riddoch, the medical officer in charge of the Empire Hospital,

¹ H. Head and G. Riddoch: The automatic bladder, excessive sweating, and some other reflex conditions in gross lesions of the spinal cord. *Brain*, London, 1917-18, xl, 149-263. G. Riddoch: The reflex functions of the completely divided spinal cord in man, compared with those associated with less severe lesions, *Ibid.*, 264-402.

Vincent Square, have carried further Professor Sherrington's work on the decerebrate animal, particularly as regards the problems of postural co-ordination. While the object of the authors is to consider the physiological principles underlying the clinical manifestations, the practical outcome of their careful observations on these paraplegic patients is very important, especially as regards the vesical condition which has such an essential bearing on prognosis. After a severe spinal injury complete retention may, if a catheter is not passed, be succeeded by cystitis and death before any signs of the complete act of automatic micturition can occur; if a catheter is passed so that overdistension and infection of the bladder are prevented, retention usually passes off, and eventually the bladder automatically empties itself. The bad effect of overdistension of the bladder must be borne in mind in washing out, for considerable pressure, such as may be obtained by raising the vessel to a height of several feet above the bed, easily overcomes the contractile power of the bladder and so only adds to its contents. The "automatic bladder" may in favourable circumstances—namely, the absence of cystitis, toxæmia, and fever—become established after a complete transection of the cord and also after complete destruction of the cauda equina; but there is the essential difference that when the automatic bladder exists independently of the spinal cord it is impossible to influence it reflexly by stimulation. The subject of the innervation of the bladder and urethra is reviewed by Dr. Fearnsides as an appropriate introduction to these observations.

When the control of a segment of the spinal cord is removed by a complete division, the discriminating and specific character of a normal reflex, such as the scratch reflex, is lost, and after the shock has passed off the lower part of the cord gradually regains its reflex activity, which is now uncontrolled; as a result stimulation leads to widespread discharge of motor energy overflowing into visceral channels; thus, stimulation of any part of the skin of one lower extremity, or even of the abdomen, may lead to characteristic flexor spasm extending to both sides, evacuation of the bladder and rectum, and excessive sweating. In this reflex the bladder is emptied when it contains less than half the amount that the automatic bladder usually discharges; and this "facilitation" of the automatic bladder is a good index of the widespread effect of a stimulus, and is seen only when the postural reflexes are absent, as in complete division of the cord. The excessive sweating—a remarkable feature of these cases—is due to activity of the nervous system below the lesion in the cord, and can be excited by almost any stimulus sending afferent impulses into the cord below the lesion, such as scratching the skin, washing out the bladder, or an enema. The massive or "mass-reflex" is part of the primitive protective reflex to pain, and not part of the normal postural reflex, whereas in cases of incomplete division of the cord the lumbar centres may still be inhibited by the pre-spinal centres and the postural reflexes persist.

In his complementary article on the reflex functions of the completely divided spinal cord in man (based on eight cases proved at operation) compared with those associated with less severe lesions, Dr. Riddoch shows that the clinical picture hitherto given as characteristic of a complete division of the cord is imperfect, and describes three stages: (1) of muscular flaccidity, corresponding with the period of deep depression from "spinal shock," and lasting from one to three weeks, with absence of superficial and tendon reflexes, toneless muscles, and retention of urine and

faeces; (2) of reflex activity, with the mass-reflex; and (3) of gradual failure of the reflex functions of the isolated spinal cord due to toxic febrile complications; the mass-reflex is no longer obtained, and the reflexes disappear, the extensor tendon jerks going first. There are no manifestations absolutely diagnostic of anatomical division of the cord, but some cases of severe damage to the cord with abolition of motion and sensation and with automatic action of the bladder and rectum show certain manifestations not present in cases with proved anatomical division of the cord. Movements of the flexor type were the only primary motor reactions observed in complete transection, whereas in the contrasted group of cases the involuntary movements may simulate progression or be entirely extensor. The clinical picture in complete division of the cord resembles that described by Babinski and Walshe as "paraplegia in flexion," and is comparable with that of the "spinal" animal, while their picture of "paraplegia in extension" is like that in the less severe spinal injuries, and comparable to that of the decerebrate animal.

MEDICAL PRACTITIONERS UNDER THE MILITARY SERVICE BILL.

THE Military Service Bill, which was read a third time in the Commons on Tuesday, April 16th, reached the Lords on Wednesday, and will, no doubt, receive the Royal assent before the end of the week. The first clause gives power by Order in Council to raise the age to 56 as respects men generally, but as the bill itself fixes the higher limit in the case of medical practitioners they will be subject to it probably before these words are in print. The position is one of some difficulty, and will require careful handling. We are therefore glad to learn that the Central Medical War Committee is already in conference with the Ministry of National Service and the Insurance Commissioners with regard to it. In the debate on April 12th on the part of the first clause which dealt with the special medical provision, the Minister of National Service said that the professional committees recognized under the Military Service Act, 1916, which had power to deal with claims for exemption made by duly qualified medical practitioners, had now been compelled to report that as the result of the withdrawal of medical men for the army the supply was very short. The number of practitioners available in every district had been ascertained, and it appeared that in some districts where young fit men were really as necessary as in the trenches (he instanced munition areas) the position had become serious. On the other hand, it was believed that there were in some residential cities doctors of the higher ages who were really in excess of local requirements. The professional committees agreed that many of them could probably be taken for work in the base hospitals, but Sir Auckland Geddes went on to say that appeals were being made to individual doctors to move into districts where the supply of medical practitioners was scanty. A certain number had, with great public spirit, responded, but more were required. At a much later stage of the debate, when the question of industrial conscription was raised by members of the Labour Party, Sir Auckland Geddes said that there was not the slightest intention to make use of powers the Act would confer to compel men to do things in civil life, and he repudiated any intention of devising a scheme of industrial compulsion. The context seems to us to show quite plainly that he was not thinking of the medical profession, that matter having, in fact, been settled on April 12th after a debate, which is reported at p. 462. We are not in a position to say exactly what may have been in the Minister's mind when he referred to the need

of inducing individual doctors to move out of residential into industrial districts, but we interpret his remarks to mean that the Ministry of National Service desires to put into force a system of substitution. Under such a system medical men in residential districts, where their services, it is considered, can be spared without injury to the civil population, would be expected to undertake work in other districts, either in the poorer parts of the same town or in some other town. We have no doubt that the response of the medical profession will be good, but we hope that it may be found possible to attain the desired result by way of what may be called "local substitution"—that is to say, a scheme by which a medical practitioner would undertake additional work in the neighbourhood in which he resides. The response, we feel sure, would be readier and more general were it not that the impression persists that many of those serving in the R.A.M.C. abroad, and even at home, are very far from finding their time fully employed. This point was made both by Sir Watson Cheyne, who was a member of the Committee of Inquiry which went to France last autumn, and by Major David Davies, who has been very persistent in asking for publication of the report of that committee. Sir Henry Craik, the member for the Universities of Glasgow and Aberdeen, also made a special appeal for the exercise of greater economy of resources on the part of the Medical Department of the War Office. He had, he said, received bitter complaints from medical officers eating out their hearts with anxiety to do work but could not find it; instead, they found themselves forced into some place where they were not fully used. Doctors, he said, were ready to accept the burden imposed by the clause if they could be certain that the use of their services by the army would be more economical and more effective than in the past.

THE DEMAND FOR AN INCREASED INSURANCE CAPITATION FEE.

THE special conference of representatives of Local Medical and Panel Committees, which was held on April 11th, is reported in the SUPPLEMENT this week. The outstanding question before the meeting was the policy to be adopted with regard to the demand for an increased capitation fee put forward by the last annual conference, and the Government's reply that no proposal for a general increase of remuneration could be entertained. Early in the proceedings the Chairman of the Insurance Acts Committee informed the conference that that Committee, after carefully considering the position in the light of all the information at its disposal, had come to the conclusion that while maintaining the equity of the claim for an increased capitation fee, the demand should not be pressed at the present moment. This opinion, it scarcely need be added, was based primarily upon the patriotic desire not to embarrass the Government in any way during a grave national crisis. In order to bring the matter to a clear issue it was decided to take at once a motion urging panel practitioners not to renew their present contracts next January. As an amendment to this, in the opposite sense, it was proposed that while still maintaining the justice of the demand for an increased capitation fee, and protesting against the tone of Sir Edwin Cornwall's reply, the conference, as a matter of patriotic duty, should not press the general claim at the present moment. This amendment clearly expressed the wish of the meeting, and, as a substantive expression of policy, it was carried by an overwhelming majority. While no one could be satisfied with the existing arrangement, the general feeling was obviously against any action which would increase the Government's difficulties in a national emergency, or might suggest to the public mind that medical practitioners put professional interests before their duty as citizens. The Chancellor of the Exchequer indicated, however, on March 15th that the Treasury was

prepared to consider an equitable scheme for meeting the increased expenses of practice, especially travelling expenses, as well as proposals for increased remuneration, on the ground of the higher cost of living, for doctors with professional incomes under £500. The conference accordingly instructed the Insurance Acts Committee to take steps to secure such additional grants and to devise equitable plans for their distribution. It was further decided that the methods of distribution of all the available funds, and the general financial arrangements and terms of service, needed early reconsideration. Lastly, the report of the president of the Institute of Actuaries upon his investigation into the constitution of the central pool was received and approved.

THE POSITION OF SCIENCE IN EDUCATION.

A COMMITTEE was appointed by the Prime Minister in August, 1916, to inquire into the position of natural science in the educational system of Great Britain, especially in secondary schools and universities, and to advise what measures are needed to promote its study, regard being had to the requirements of a liberal education, to the advancement of pure science, and to the interests of the trades, industries, and professions which largely depend upon applied science. The chairman of the committee was Sir J. J. Thomson, president of the Royal Society, and the members consisted in about equal proportions of persons especially concerned in general education, in science, and in the application of science to industry. The medical members were Dr. Henry Head, F.R.S., and Professor E. H. Starling, F.R.S. The report of the committee, issued this week,¹ fills, with its appendices, eighty-four pages, and will afford food for much careful study. It is concerned mainly with England, but it contains short sections on Wales and Scotland. Its effect may be summed up in the recommendation "that concerted efforts should be made by employers, teachers, local education authorities, and the state to increase the flow of capable students to the universities and higher technical institutions with a view to securing the larger supply of trained scientific workers required for industrial and other purposes." It recommends that natural science should be included in the general course of education of all up to the age of about 16; that the tests of such a course recommended in the report should, with necessary modifications, be accepted as the normal qualification for entrance to the universities and professions; that a large increase in the number of scholarships at all stages of education is necessary, and that periodical inspection under the direction of the state should be compulsory on all schools. Finally, it states emphatically that real progress in education depends on a revolution in the public attitude towards the salaries of teachers and the importance of their training. Recognizing that no profession is more affected by the way natural science is taught in schools than medicine, since it is directly based on a knowledge of chemistry, physics, and biology, the committee devotes a special section to medical education and makes certain recommendations. It points out that there are two standards for admission to a medical school—the senior, which is equivalent at least to a university matriculation examination, and the junior, which is considerably lower and is taken by about 40 per cent. The committee considers that the senior examinations would be a satisfactory test for entrance into the medical profession if one or more natural science subjects were offered by the candidate and if the teaching of natural science were materially improved in secondary schools. It is of opinion that some substitute for the junior certificates must be found which will make it certain that the pupil has passed through an educational course in the natural sciences. At present the "junior certificates are taken by boys who either left school at about 16 for no very definite cause, or were too lazy or too

¹ Cd. 9311, price 9d.

ignorant to pass the higher examinations, or who perhaps on account of poverty do not aim at a university course in medicine." These certificates are granted on the result of an examination in four subjects—English, mathematics, Latin, and an additional language, classical or modern. No evidence of instruction in natural science is required, nor any certificate of attendance at any educational course, whether at a secondary school or elsewhere. It is obvious, the report continues, that such a method suffers from two grave defects: first, there is no guarantee that the candidate has received any instruction in natural science, the bedrock of his future vocation; secondly, there is no evidence to show that he has gone through a coherent educational course in any of the subjects demanded. He may merely have been crammed by some institution which exists for this purpose. As the door has been opened by the universities of London, Liverpool, Leeds, Sheffield, and Birmingham, the committee considers it too late to attempt to retain Latin as an obligatory subject in the examination for entrance to the medical profession, and advises that the first school examination should, subject to certain modifications, be recognized by the General Medical Council as qualifying for entrance into the medical profession. This examination would be held at the completion of the general course of study at a secondary school to test the results of instruction in English subjects, languages, mathematics, and science, in the manner suggested by the Board of Education, but the committee recommends that every boy should be required to satisfy the examiners both in science and mathematics. The committee considers that something more than a simple pass should be demanded at this examination from a medical student, and that a candidate who has obtained a simple pass should only be allowed to enter on the study of medicine by passing the second school examination, which the Board of Education has suggested would be suitable for pupils of about 18. The committee further recommends that medical students should be allowed to take the first professional examination in chemistry and physics and in biology before entering a university or medical school, and that more scholarships should be provided for candidates of both sexes, tenable throughout the medical course.

NATIONAL KITCHENS.

THE Food Controller, acting under the powers conferred upon him by the Defence of the Realm Regulations, has issued an Order—to be known as the National Kitchens Order, 1918—permitting local authorities to establish and maintain in their areas national kitchens and distributing dépôts, to sell food and drink for consumption on or off the premises, and to do such other things as are necessary for fulfilling this purpose, subject to conditions laid down by the Food Controller. The powers granted to it may be delegated by a local authority to its Food Committee, or other committee, and approved combinations of neighbouring local authorities will be encouraged by the Food Controller. Such kitchens and dépôts, and the food and drink supplied by them, must at all times be open to inspection by authorized persons. The Local Government Board, by arrangement with the Food Controller, has issued regulations conferring upon local authorities and their officers the powers and duties necessary to conform with the National Kitchens Order, with the proviso that no such authority shall delegate any power to levy a rate or borrow money, the expenses incurred in the execution of this Order being defrayed as if they had been incurred in the execution of the Public Health Acts. The Ministry of Food has also issued a memorandum on national kitchens for the information and guidance of local authorities and committees. This explains that the present position of the food supply has made an organized effort of the kind both necessary and desirable. The advantages of national kitchens are summarized thus: (a) Economy of food and fuel; (b) the

supply of nutritious and well-cooked food at reasonable prices—that is, on a self-supporting, but not profit-making basis; (c) the substitution of skilfully prepared and properly cooked wholesome meals for makeshift meals; (d) economy of labour by the collective preparation of food. Experience of the kitchens already in use has satisfied the Food Controller that the benefits to be derived from the operation of suitable schemes only need to be known to be appreciated. He therefore wishes local authorities to regard the provision of national kitchens as a matter of national urgency and a form of insurance against food shortage. Every scheme must be approved by him before they are put into operation. Existing kitchens will require approval, and should be included in proposed schemes. The Treasury has sanctioned the payment to a local authority, in respect of an approved scheme, of an out-and-out grant of one quarter the cost of equipment; the advance of a second quarter of such cost on condition that the amount will be repaid out of the financial results of the kitchen rateable with the amount provided by the local authority; and a similar Treasury grant and advance in respect of approved schemes for village canteens. The balance of the cost will be borne by the local authority. Schemes should take into account the facilities available (including the equipment in premises now closed) for the supply of cooked food through the medium of restaurants, eating-houses, and other catering agencies, and co-operation with the proprietors of such establishments is recommended. The memorandum contains various practical suggestions with regard to the selection of premises, and an outline of procedure for organizing kitchens and dépôts. The point is insisted upon that a national kitchen is a business proposition, and must not be conducted as a charity. The Food Controller is willing to aid in the preparation of schemes, especially as regards the character of kitchens and their equipment, estimates of cost, menus, and other information relative to scientific and economic cookery, accountancy, methods of transport of cooked food, and the supply of supervisors and working staff. All communications on this subject should be addressed to the Director of National Kitchens, 4, St. Paul's Churchyard, London, E.C.4. The cordial support of the medical profession can be assured beforehand, since the communal kitchen has dietetic and economic advantages which are self-evident. We foresee great developments of the idea, not only during the present food crisis, but also in the lean years which must be expected after the war. It may perhaps form an essential feature in social reorganization.

THE EFFECT OF GLARE ON THE EYE.

IN a paper on the physiology of the retina, read before the Illuminating Engineering Society on April 16th, Professor W. M. Bayliss, F.R.S., discussed in the first place the structure of the retina and the photochemical reaction of the visual purple, and in particular the time course of the reaction as illustrated in records of electrical changes accompanying light action in the eyes of certain animals. He went on to express the opinion that excessive contrasts produced injurious effects upon the retina. It was difficult to say exactly what occurred in the retina when the unpleasant sensation resulting from excessive contrasts was experienced, but after very intense and prolonged exposure detectable damage to the cell structures could be made out. The presumption was that any glaring conditions which caused discomfort were prejudicial, and, although in mild cases the discomfort was only temporary, and the recuperative power of the eye might prevent appreciable injury, yet habitual subjection to moderate glare would probably hasten failing sight in later years. The difficulty of imposing definite limits to what could be accounted glare arose from the varying power of different eyes in respect of resistance and recuperation, and from the fact that the eye

at any moment was affected differently by a light of given brightness according to its state of adaptation. It had been suggested in America that the ratio of brightness of objects in the field of view should not exceed 100:1, and while it would be premature to say that a physiological basis for this suggestion was established, it seemed a reasonable figure to take. No unshaded bright sources, such as filaments or incandescent mantles, should be allowed to fall within the direct range of vision; if such bright sources were permissible anywhere, it was immediately overhead, in which case the eye was shielded by the brow and upper eyelid. The same difficulty, owing to the complexity of factors on the physiological side, was to be found in attempting to contrive a general test for eye fatigue such as could be applied to demonstrate the effect of different systems of illumination. This involved the question of bodily health and fatigue as well as eye-strain in particular. The difficulty of establishing this general fatigue test was also indicated by Mr. Treacher Collins in the subsequent discussion. He said that the limits of fatigue varied widely among different people, according to the prominence of the eyeball in the orbit (the deep-set eye, other things being equal, was less liable to fatigue); the size of the pupil, the length and colour of the eyelashes, and the pigment in the skin of the eyelids were further factors to be taken into account, and he had himself found that to smear a little charcoal over the eyelids when travelling in glaring sunlight was some protection. The question could not be considered without bringing in also the great differences between individuals in respect of nervous sensibility and imagination.

MILITARY DOCUMENTS, MAN POWER, AND PROMOTION.

We felt it our duty a short time ago to call attention to the multiplicity of the forms to be filled up and the documents to be prepared by army medical officers, and the amount of clerical work of a routine kind they were called upon to undertake. We were disposed to attribute this to the persistence of old regulations, which were only applicable to the small army this country maintained in peace. We were assured that this was not the explanation, and that as a matter of fact the old regulations did not require so much clerical work from medical officers as many were doing in this country. It appeared, therefore, that the obligations had been placed upon them under a misapprehension, and we cannot doubt that they have ceased to labour under this disadvantage. That great complexity of clerical work can arise even in a new department is shown by the letter from Lord Rothermere, Secretary of State for the Royal Air Force, published in the newspapers on Monday. Speaking of that department, he said that there was much duplication, and that a great many excellent officers were engaged in filling up unnecessary forms and carrying out circumlocutory methods of conducting business. It is quite clear, therefore, that the multiplication of documents and forms to be written, filled up, or signed, is one of the dangers which has to be guarded against in the working of any public department. The abuse is very serious in France, and one of the Paris newspapers published a year or two ago a whole sheet, the size of a page of the *Times*, reproducing in facsimile all the notes, stamps, and signatures accumulated about a simple question. The first document, sent to the officer commanding a particular regiment, set out that the French War Office had decided that men who met certain conditions should be removed from their units and sent elsewhere, and the question was, how many men in his regiment fulfilled the conditions. The document started on its voyage through "the usual channels," and in the various offices and commands was duly annotated, signed, and stamped. Eventually it reached the officer commanding the regiment, who replied that there were no men in his regiment who fulfilled the

conditions. Whereupon the document started on its return journey, and before it got back to the original inquirer had attained the dimensions we have mentioned. There is one other point in Lord Rothermere's letter which seems worthy of reproduction here. It deals with promotion. "I intend," he wrote, "that the door shall be thrown wide open for promotion of any and every officer whose merit, first from the disciplinary and then from the flying or technical point of view, entitles him to advancement. The Regular officer must always receive priority of consideration. He is the backbone of the three fighting Services, but after all his claims have been met there should be wide scope for the promotion of temporary and Special Reserve officers, for in the Air Force these officers comprise more than 90 per cent. of the entire staff. So far not one of them has risen to the rank of Brigadier-General on any of the battle fronts or in the training divisions at home."

A NEW SPIROCHAETE IN RAT-BITE FEVER.

RAT-BITE FEVER is fairly common in Bombay, but as the cases usually come under observation weeks or months after the initial phases have passed and when complications have supervened, Row¹ has not in ten years' search been able to demonstrate the virus of the disease until now. A schoolboy, aged 15, developed fever after an incubation period of ten days from a scratch by a rat, and nine days later a papular, slightly nodular eruption gradually spread over the face, neck, trunk, and limbs; it suggested a papular syphilide or even nodular leprosy. Blood from the median basilic vein showed a slight leucocytosis, but was sterile, free from spirochaetes, and gave a negative Wassermann reaction. Films from blood and serum squeezed out of the papules contained spirochaetes, 2 to 3 μ in length, with only two or sometimes three curls, and so quite different from the much longer spirochaete described in 1916 as the cause of rat-bite fever by Futaki, Takaki, Taniguchi, and Osumi in Japan, which was midway in length between *Spirochaeta pallida* and *S. duttoni*. Row's spirochaete was pathogenic to mice and rats. The patient was completely cured by the injection of neo-salvarsan, the eruption rapidly disappearing on the third day after the injection. This case confirms the Japanese view that rat-bite fever is a spirochaetosis, but it raises the interesting question as to the possibility that different spirochaetes may cause the disease. Observers in America—Blake, Tileston, and Tunncliffe—described a streptothrix in rat-bite fever which is said to be identical with Schottmüller's, but Row suggests that this was a secondary or possibly mixed infection.

ORTHOPAEDIC COMMITTEE: MINISTRY OF PENSIONS.

The Minister of Pensions has appointed a consultative Orthopaedic Committee, to consult with and advise the Ministry on all matters relating to orthopaedics. The chairman is Sir Arthur Boscawen, Parliamentary Secretary to the Ministry of Pensions, and the members are Colonel Sir Robert Jones, C.B., Major Bristow, R.A.M.C., Major Elmslie, R.A.M.C., Sir John Collie, Director of Medical Service to the Ministry of Pensions, and Dr. Fletcher Porter, Deputy Director of Medical Service to the Ministry of Pensions. We are glad to know that this step has been taken, and can only regret that it was not taken earlier. We must regret also that the Minister has not given any intimation of his intention to establish an orthopaedic branch of the medical department which would command the permanent services of one or more experienced orthopaedic surgeons. The committee contains three officers eminent in this speciality, but we are not informed how often they are to meet. We fear that an occasional sitting, even of so strong a committee, will not meet the necessities of the situation, which we regard as very grave.

¹ R. ROW, *Indian Journ. Med. Research*, Calcutta, 1917, v, 386-393.

THE Council of the Royal Society has appointed a committee to investigate and report on the possibility of obtaining and replacing food materials and other necessities by the utilization of natural products not hitherto generally employed for such purposes. Suggestions as to such products and the means of organizing their collection should be addressed to the Secretary of the Natural Products Committee, Royal Society, Burlington House, Piccadilly, London, W.1.

Medical Notes in Parliament.

Military Service Bill.

The Extended Age for Medical Men.

THE provision in the Military Service Bill whereby the age for military service for duly qualified medical practitioners is to be raised to 56, as against 51 for ordinary service, came before the House of Commons in Committee on April 12th.

A debate arose on an amendment moved by Mr. Leif Jones for the purpose of obtaining information, and during its course Sir Watson Cheyne stated the position of the medical profession. He was quite sure that its members were not opposed to the proposal, and to him it seemed that an honour had been done to them. They particularly trusted the Minister of National Service because he belonged to the same profession. Nevertheless it was an extremely serious thing, both for the doctors themselves of this age and for the community at large, for them to be called up, and it would require a very great deal of care and tact to do it without injury. Referring to the sacrifices that the profession had made, Sir Watson Cheyne said he knew many young men who volunteered early in the war and were absolutely ruined as a result, financially and in health also. It was a great problem for these men how to reinstate themselves, and yet as long as they were young they did not lose hope, as they had time to begin again. That applied to young men of 20 to 30, but when a man was between 50 and 55 he could not recover his position. It was hoped that in selecting these men the Minister would have special regard to this point. The reason for calling on men of this age was, he presumed, that they were wanted to take the place of others who were fit to go abroad. He did not suppose for a moment there was any idea of putting men of 55 into the trenches. A man at that age had not the physical ability to go into the trenches, but he might have the brains and experience to help the country at home. Hence he suggested that to a certain extent they should be part-time men. Let them be put in charge near their own homes—for instance, in London, to work in a hospital—and let them give the greater part of their time there and yet be able to go home to keep things together. That was the sort of solution. It would be very hard if a man were taken from active practice and had nothing whatever to do abroad. That had happened over and over again. Men who were working night and day in London had been sent abroad and had half an hour's work in the whole day. That broke a man's heart. He wanted only to draw the attention of Sir Auckland Geddes to the point, that he as far as possible should try and conserve doctors' practices at the same time getting as much work out of them as possible.

Sir Auckland Geddes said that the Military Service Act of 1916 gave power to provide for the establishment of professional committees to deal with claims for exemption made by duly qualified medical practitioners. In other words, the dealing out, if he might use the expression, of the doctors for the armed forces of the Crown was, in fact, controlled by professional committees. They had now reached the stage at which the professional committees said: "There are only two possibilities in front of us: Either we are to take away the only doctor remaining in the locality and leave no one, or we have to arrange when we take that man to move some one else into his locality." There were districts in this country where, as the result of the withdrawal of medical men, the supply available was very short and where the young fit man was really necessary, just as necessary as he was in the trenches, and working practically as hard day and night. It was no good talking about putting an old man who did not know the district and did not know the people into that position. In the medical profession youth and fitness were now required for certain districts at home just as much as at the front. But there were great base hospitals where the work was not normally very hard, and it

therefore appeared wise to see if use could not be made of some of the older men of the medical profession who were at present in this country. The number of medical men available had been ascertained in every district and the number of the population they might have to look after, and it was found that there were in some of the more comfortably off residential cities—not the great manufacturing cities but cities for the retired class—doctors of ages from 50 to 54 who were really in excess of local requirements. These had, comparatively speaking, a small number of possible patients at any time. The professional committees agreed that many of these men could go without dislocating either the public health service or the ordinary service of attendance on the sick, and were sufficiently physically fit for work in the base hospitals. The question for Parliament, therefore, was whether the medical demands for the forces of the Crown were to be met in the way that made least disturbance at home and without harm to the civil population, or was the age for doctors to be left at the same level as for other sections of the population, a kind of double-shuffle going on. There were always men coming back from overseas to their practices to release a partner or something of that sort. If medical men had to be moved from town A to town B so that the practitioners in town A might replace practitioners in town B who had gone into the service, an enormous number of problems would be raised as to the adjustment of practices and compensation for removal from positions. Were it true that the doctors were now equally spread over the country so that there was an equal possibility of medical attendance for persons in civil life there would be no need to raise the age. But that was not the case. Doctors were unfortunately thin in the great munition areas, and no more could be taken out of those areas. Appeals had been made to individual doctors to move into districts which required greater service, and with great public spirit a certain number had responded. But the medical profession was composed of human beings, and there were human beings who would do these things, and there were human beings who said, "No, I would rather not." The object of the clause, however, was to enable the situation to be dealt with in the interests of the civil population. The administration of the power proposed with regard to the medical profession was in no sense under the War Office until the medical man actually donned the uniform of the R.A.M.C. The provision would be worked by the Ministry of National Service, with the National Insurance Commissioners, the Local Government Board, and the professional committees as the executive machinery for calling up and distributing the men; he believed he was correct in saying that all these bodies agreed that the power which was being asked for should be granted.

In the course of the discussion Mr. Pringle said that before giving this power to the Government they ought to insist that the War Office should exercise rigid economy in the use it made of doctors in the army, and also that they should be used in the best way. Merely clerical work should not be thrown upon them. He was told that when the committee of investigation into the medical service in France was there the authorities reduced the number of doctors in the casualty clearing stations, and there was a most rigid economy wherever the committee went. Sir Watson Cheyne interpolated that nothing of that kind deceived the committee. Brigadier-General McCalmont supported Mr. Pringle's appeal for assurance that the medical officer was put to the work for which he was most suited. In regard to Ireland he thought they would be able to economize a great deal in medical officers if there was a certain amount of give-and-take between the civilian element and the military authorities. If the military authorities were going to say, "We must have a military medical officer in such and such a town," and if the Ministry of National Service had no power to say, "No; it is quite enough for you to use the local civilian doctor," much service would be lost. He mentioned Ireland because there were many small garrisons which required medical attention, and probably the problem was more acute there than elsewhere. Sir Thomas Esmonde agreed with Sir Watson Cheyne as to the course to be adopted. Every one who knew anything of the work of the R.A.M.C. was aware of the enormous amount of time wasted in filling up forms. He asked Sir Auckland Geddes to consult the medical authorities as to whether it was not possible to take medical students of three years' standing for first-aid work at the front and thus relieve doctors for more important work. Major David Davies, referring to the work of the committee of inquiry in France, said he had asked that this committee should include a lay element, and that the

inquiry should be extended. He thought the House should have had the report of the committee before it. At the time this committee was appointed it was understood—although he knew that that had been denied—that under the terms of reference it would investigate arrangements in this country as well as in France. The medical service in the East ought also to have been included. Sir Henry Craik, as the representative of some 5,000 doctors, supported the view that some further form of compulsion was desirable. He had received communications from some of his constituents complaining that certain men in advantageous positions were stealing away the practices of others. It was a very serious question, and he thought it was on that ground very largely that the profession as a whole were in favour of some sort of regulation and organization such as was proposed in the bill. While the profession welcomed the proposal, it felt that it placed a great responsibility upon the authorities. He therefore joined in the appeal that there should be greater exercise of economy of resources on the part of the medical department of the War Office.

Sir Auckland Geddes, in a further reply, said that there had been consultation with the medical profession and with the authorities representing the central governing bodies, and there had been a very strong expression of opinion from certain members of the profession that the age should be raised to 60. In answer to Mr. Timothy Healy, Sir Auckland said that safeguards for the medical profession in Ireland would be worked along lines similar to those which were followed in England, where there were committees of representatives of the Royal Colleges, of the British Medical Association, etc., actually working as professional tribunals. He added that the whole object of the present organization was as far as possible to give part-time work to the medical profession.

The Committee divided on the clause, which was carried by 249 votes to 95.

During the further proceedings in Committee Sir George Cave agreed to modify the proposal under which there should be power by proclamation on national emergency to cancel certificates of exemption *en bloc*. It was explained that the National Service Ministry already had power to cancel exemptions granted on grounds of occupation. The Home Secretary agreed to omit from the scope of possible proclamation men who were given exemptions on the ground of ill health, and also to omit conscientious objectors. The number of cases, he said, in which the tribunals had acted on their own judgement against the views of the medical boards were few; many of the conscientious objectors were of weak physique and deficient in other ways. They were a class of little military value. Thus the power to be given for cancelling exemptions by proclamation would be limited to the cases of serious hardship on business or domestic ground. What was in mind was only a period of crisis in which all personal considerations ought to give way. He accepted an amendment that Orders in Council should be laid on the table for fourteen days, within which period it would be open for an address to be presented for annulling the Order.

Mr. Hayes Fisher explained that it was intended that the Local Government Board should nominate the local tribunals and also frame regulations regarding them. The appeal tribunals would be retained in much the same form as now, but their personnel might be altered. Sir George Cave subsequently undertook that there should be equal rights of appeal both for the men and the National Service Department. The proposed inclusion of ministers of religion was omitted; those who desired to serve could still do so if they had permission from their superiors.

During the discussions Sir Auckland Geddes replied to a number of questions as to his statement last week to the effect that it was estimated that the number of men it was expected to call up and post for service in the army or air force during this year was 7 per cent.; the remaining 93 per cent. would remain in civil life under conditions precisely similar to those under which men from 35 to 43 were in civil life now; there was no intention of compelling those men who remained in civil life industrially. It was not competent for a tribunal to grant certificates of exemption conditionally upon a man remaining employed by any specified firm or individual; the exemption must always be upon the ground that the man was engaged in a certain occupation. He added: "I want to say generally that there is not the slightest intention to make use of these powers in this Act to compel men to do things in civil life." There was no intent on to devise a scheme of industrial compulsion with regard to the 93 per cent., nor to depart from the general lines of procedure followed throughout the last two years. It was intended to take every young man who could be taken before drawing upon older men; but while these older men were of comparatively small value for front line trench work, they were of enormous use in connexion with the ground work of the Royal Flying Corps, in the Royal Army Medical Corps, the Ordnance Corps, and the Garrison Artillery.

On the third reading, Mr. Barnes, the Labour Minister, and Mr. Lloyd George definitely announced that the Government would introduce a Home Rule Bill which would include Ulster within the authority of an Irish Parliament, and pledged itself to pass this measure subject to the approval of the House. If the measure were rejected by the Lords the Government would

resign. It was hoped that the Home Rule Bill would be on the statute book before the conscription provisions operated in Ireland, but the Government was bound to proceed with this provision for Ireland, as well as the rest of the country, without waiting for the Irish Parliament to be set up, for that operation would take time, and men were wanted.

The Sexual Offences Bill.

Lord Beauchamp has introduced into the House of Lords a bill intitled "An Act to make further provision with respect to the punishment of sexual offences and for the treatment of venereal diseases and the prevention of indecent advertisements; and matters connected therewith."

Clause 1 makes it an offence, punishable by imprisonment up to two years with or without hard labour, for any person suffering from venereal disease in a communicable form to have, to solicit, or to invite intercourse with, or wilfully to communicate such disease to another person, provided that no one shall be convicted who proves reasonable grounds for believing that he or she was free from communicable venereal disease at the time of the alleged offence. To ascertain whether a person, convicted of any offence, which under this clause would be caused or aggravated by the existence of communicable venereal disease, is in fact so suffering, the court may order the offender to submit to medical examination and tests, these being conducted in the case of a female, if she so desires, by a medical woman. False accusations are made punishable by heavy fine or imprisonment or both. Clause 2 forbids common prostitutes and night-walkers to loiter in thoroughfares or public places for the purpose of prostitution or solicitation, on pain of a month's imprisonment. Clause 3 stiffens the penalties against brothel keepers and the like. Clause 4 imposes a fine not exceeding £20 upon the occupier of premises used for public entertainment convicted of allowing these to be the habitual resort, for whatever purpose, of reputed prostitutes. Clause 5 prohibits in the most comprehensive terms the treatment of venereal disease otherwise than by duly qualified medical practitioners, and forbids the advertisement of any such treatment whatever, except by local or public authorities with the sanction of the Local Government Board, or in publications sent only to medical practitioners, or to wholesale and retail chemists for the purpose of their business. The penalty for contravention of this clause ranges from a fine not exceeding £100 to two years' hard labour, and the Venereal Diseases Act, 1917, is explicitly repealed. Clause 6 forbids the display or transmission of "any picture or printed or written matter which is of an indecent or obscene nature," including any advertisement which relates to venereal disease, nervous debility, or other complaint or infirmity arising from or relating to sexual intercourse, or which suggests, directly or indirectly, either the taking of anything for the purpose of procuring miscarriage or abortion, or the use of any premises for immoral purposes. Clause 7 seeks to punish acts of indecency with persons under the age of 17, consent being no defence, and Clause 8 would amend the Criminal Law Amendment Act, 1885, in the same way. Clause 9 gives power to exclude the public from courts, and to prohibit reports of proceedings where this seems desirable in the interests of decency, morality, humanity, or justice. Venereal disease is defined as meaning syphilis, gonorrhoea, or soft chancre; and the short title is "Sexual Offences Act, 1918."

Appeals on Medical Grounds.—Replying to a question in the House of Commons on April 18th Mr. Hayes Fisher (President of the Local Government Board) said that, so far as he was responsible for issuing the regulations, he did not contemplate taking away any rights of appeal on medical grounds to the appeal tribunals. Attested men, alike with unattested men, were examined as to their medical fitness for military service by National Service Medical Boards. Attested men had the same rights as unattested men under the rules (which had been issued by the Local Government Board) of applying to the appeal tribunals for leave to be examined by the medical assessors if they were dissatisfied with the grading by the National Service Medical Boards.

Extra Meat Allowance for Invalids.—In reply to Sir Clement Kinloch-Cooke, Mr. Clynes said there was no evidence that any undue suffering or hardship was caused to invalids under the present food regulations. If advantage was taken of the possibilities that were open in the use of fish, eggs, milk, meat extracts, and other unrationed food, no invalid need suffer in any way from the scarcity of butcher's meat. The Food Controller was acting throughout in consultation with scientific and medical authorities and was now considering whether some modifications should be made in the regulations. In reply to Sir Henry Craik, he said that the department was in consultation with those concerned to see whether some extra rations should be allowed on medical advice to patients suffering from loss of blood after surgical operations.

A CORRECTION.—In the debate last week on the Military Service Bill Sir Donald Maclean said that the Minister of National Service would agree that it had been the experience of the last two years that the sickness casualties of men between the ages of 35 and 41 had been two and a half times greater than those of men who were between the ages of 27 and 35. By a slip of the pen our note last week repeated the first-named figures.

THE WAR.

THE EAST AFRICAN CAMPAIGN.

A DISPATCH from Lieut.-General Sir J. L. van Deventer, Commanding-in-Chief British Forces in East Africa, dated January 21st, 1918, and covering the period from May 30th to December 1st, 1917, has been issued by the War Office. The health of the troops after the wettest season known in German East Africa for very many years was far from good. None but the indigenous African could stand the climate of the coastal belt in the rains, and the conditions on the banks of the Rufiji were little better. Europeans, Indians, and Africans recruited from any but low-lying areas accordingly suffered terribly from malaria, and the "paper strengths" of the force bore no proportion whatever to the numbers of men available in the field.

After describing the progress of the campaign towards its successful conclusion in the conquest of the last German colony, the Commander-in-Chief pays a warm tribute to the medical services. These, he says, had many, and at times almost insuperable, difficulties to contend with. Probably in no previous campaign in the tropics had such numbers been employed, and the peculiar conditions rendered the evacuation of the large number of sick and wounded a most difficult problem. Ambulance transport over the roughest roads involved much discomfort to the patients, but evacuation was well and expeditiously carried out from the front to the railway and sea bases, and every effort was made to minimize suffering. The mobility of the force was never impaired by the retention of the sick at the front. Apart from the large number of wounded, the sick-rate from malaria and dysentery was excessive, needing large hospital provision.

The sanitary services also had a most difficult task in controlling the spread of severe infectious diseases—for example, cerebro-spinal meningitis and small-pox, which are prevalent in many parts of the country. The great number of carriers employed necessitated the formation of an elaborate medical organization, including large hospital establishments, to deal with them. It is recorded that these arrangements were most carefully considered and well carried out. Equally with the fighting troops the personnel of the medical services suffered from the extremely trying climate.

The Commander-in-Chief adds that he cannot speak too highly of the enthusiasm and good work done by officers and men of the various medical services under the command of Surgeon-General G. D. Hunter, C.B., who made every effort for the treatment, care, and comfort of the sick and wounded, at times under the most exceptional and trying conditions. The highest praise also is given to the ladies of the nursing services for their devotion to duty.

THE ITALIAN FRONT.

GENERAL SIR HERBERT PLUMER, lately commanding the British Forces in Italy, in a dispatch dated March 9th, summarizes the services rendered by the various branches of the force since he assumed command on November 10th, 1917. He states that the medical and sanitary services were well organized. The various hospitals and convalescent camps had been well arranged, and were in thoroughly good working order; while the policy of establishing general and stationary hospitals on the Riviera worked well, the effect of the hospitals being in such a good climate naturally tending to early recovery. The health of the troops was excellent and casualties were slight. Although the men felt the cold considerably during the winter, the Commander-in-Chief is convinced that they benefited much from the change after the severe fighting they had had in France.

INDIAN FRONTIER OPERATIONS.

In a dispatch on the operations against the Mahsuds, March to August, 1917, Lieut.-General Sir A. A. Barrett states that the medical services under Colonel P. Hehir, by the timely use of precautionary measures, were able to prevent the outbreak of epidemics, while the arrangements for reception and evacuation were fully adequate to deal with casualties. The provision and equipment of base hospitals and convalescent dépôts at Rawalpindi and in the Murree Hills were quickly carried out, and amply sufficed to meet all requirements.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Drowned.

SURGEON A. F. MACINTOSH, R.N.

Surgeon Alexander Fraser Macintosh, R.N., was reported as accidentally drowned, in the casualty list published on April 11th. He was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1915, and soon after took a temporary commission as surgeon in the navy.

ARMY.

Killed in Action.

MAJOR J. S. WALLACE, M.C., R.A.M.C.

Major Joseph Stephen Wallace, M.C., R.A.M.C., reported killed in the casualty list published on April 10th, received his medical education at University College Hospital, and took the diplomas of M.R.C.S., L.R.C.P.Lond. in 1915. After serving as house-surgeon to the Great Northern Central Hospital he received a temporary commission in the R.A.M.C. In the early part of 1917 he was awarded the Military Cross for conspicuous gallantry and devotion to duty when in charge of bearer parties.

CAPTAIN S. CROSS, R.A.M.C.

Captain Solomon Cross was killed in action on March 22nd. He had been previously reported missing, but a brother officer stated in a letter that after Captain Cross had attended to wounded throughout the whole of March 22nd in an exposed trench and under intense shell fire, our troops were obliged to withdraw. It was during the withdrawal and while bending over a wounded soldier that he was killed. Previous to this engagement he had been attached to a casualty clearing station. He was the youngest son of Mr. W. Cross of Darlington, and was educated at the Royal Keppier Grammar School, Houghton-le-Spring, where he gained the Heath Scholarship. Captain Cross graduated M.B., B.S.Durh., with honours, in 1899. For a few years he was in practice in Houghton-le-Spring, and latterly in Newcastle, where he specialized in diseases of the nose and throat, having previously held house-surgeonsies in the special departments of Brighton and of the Sussex County Hospitals. He was on the staff of Newcastle-upon-Tyne Hospital for diseases of the throat, nose and ears, also on the Women's Hospital. When in Boulogne in March, 1917, having joined up in 1915, he volunteered to go to the trenches, and for a period was M.O. to a battalion of the Northumberland Fusiliers. He will be much missed by friends and patients.

CAPTAIN D. W. HUNTER, D.S.O., R.A.M.C.

Captain Douglas William Hunter, D.S.O., R.A.M.C., was killed in action on March 25th. He was the eldest son of Mr. Douglas Hunter, of Jordanhill, Glasgow, and was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1901, subsequently taking the D.P.H.Camb. in 1907. He was in practice at Bradford before the war. He took a temporary commission as lieutenant in the R.A.M.C., was promoted to captain on completion of a year's service, received the D.S.O. on September 26th, 1916, for an act of great bravery and determination, and was attached to the West Yorkshire Regiment when killed. Much of his valuable work in the trenches was done in encouraging and keeping together his men.

Died of Wounds.

CAPTAIN C. E. A. WILSON, R.A.M.C.

Captain Charles Edgar Andrew Wilson, R.A.M.C., died of wounds on April 8th, aged 41. He was the eldest son of the late Rev. A. Wilson, Rector of Bedford Park, Chiswick, and was educated at Charterhouse, at St. Thomas's Hospital, and at Christchurch, Oxford, where he graduated B.A. with first-class honours in physiology in 1899, and M.B. and B.Ch. in 1902. After filling the posts of house-surgeon to the Hospital for Sick Children, Great Ormond Street, of house-surgeon to the General Hospital, Birmingham, and of honorary surgeon to the Blackheath and Charlton Cottage Hospital, he went into practice at Petworth, Sussex, where he was honorary surgeon to the Petworth Cottage Hospital. He took a temporary commission as lieutenant in the R.A.M.C. in 1916, and had

been at the front almost ever since—at first with the Northumberland Fusiliers, and then with the Rifle Brigade, being promoted to captain after a year's service.

Died on Service.

CAPTAIN W. TURNER, R.A.M.C.

Captain William Turner, R.A.M.C., died recently of pneumonia on active service. He was educated at St. Mungo's College, Glasgow, and took the Scottish triple qualification in 1900, after which he went into practice at Saltcoats, Ardrossan, where he was medical officer of Old Ardrossan parish. He took a temporary commission as lieutenant in the R.A.M.C. about two years ago, was promoted to captain after a year's service, and had served on both Eastern and Western fronts.

Wounded and Missing.

Captain T. A. Townsend, R.A.M.C. (temporary).

Wounded.

Major G. E. Ferguson, R.A.M.C.
Major B. F. Bartlett, R.A.M.C. (temporary).
Captain C. D. S. Agassiz, M.C., R.A.M.C. (T.F.).
Captain R. C. B. Briscoe, R.A.M.C. (temporary).
Captain L. A. Celestin, R.A.M.C. (temporary).
Captain T. A. Davie, M.C., R.A.M.C. (S.R.).
Captain S. W. Fisk, R.A.M.C. (temporary).
Captain P. Forbes, R.A.M.C. (temporary).
Captain A. W. Forrest, R.A.M.C. (temporary).
Captain A. W. Gill, R.A.M.C. (temporary).
Captain C. M. Gozney, M.C., R.A.M.C. (T.F.).
Captain N. B. Graham, M.C., R.A.M.C. (S.R.).
Captain J. W. Hagey, Canadian A.M.C.
Captain A. C. Hancock, M.C., R.A.M.C. (temporary).
Captain W. A. Hislop, R.A.M.C. (temporary).
Captain G. W. B. James, R.A.M.C. (temporary).
Captain C. H. S. Redmond, R.A.M.C. (T.F.).
Captain W. J. Seale, M.C., R.A.M.C. (temporary).
Captain F. N. Stewart, M.C., R.A.M.C. (temporary).
Lieutenant D. T. Harris, R.A.M.C. (temporary).
Lieutenant E. A. Sanders, R.A.M.C. (temporary).
Lieutenant A. H. Southam, R.A.M.C.

Missing.

Major J. Kennedy, R.A.M.C. (S.R.).
Captain F. Dallimore, M.C., R.A.M.C. (temporary).
Captain F. T. H. Davies, R.A.M.C. (temporary).
Captain J. A. Gilfillan, R.A.M.C. (temporary).
Captain P. H. Green, R.A.M.C. (temporary).
Captain A. C. Hepburn, R.A.M.C. (temporary).
Captain W. J. Hirst, R.A.M.C. (T.F.).
Captain H. S. Moore, R.A.M.C. (temporary).
Captain J. C. Muir, R.A.M.C. (temporary).
Captain C. E. Redman, R.A.M.C. (temporary).
Captain S. Smith, M.C., R.A.M.C. (temporary).
Captain R. M. Soames, R.A.M.C. (temporary).
Captain E. A. Walker, M.C., R.A.M.C. (temporary).
Lieutenant F. N. P. Martland, R.A.M.C. (temporary).

Prisoner of War.

Captain E. H. Griffin, R.A.M.C. (temporary), whose name was given as killed in action in the obituary columns of the *Times* of April 9th, and of whom an obituary notice appeared in last week's *BRITISH MEDICAL JOURNAL*, is now believed to be wounded and a prisoner.

DEATHS OF SONS OF MEDICAL MEN.

Beverley, Michael, Australian Infantry, eldest son of Dr. Michael Beverley of Scole, Norfolk (formerly of Norwich), killed March 26th. He had gained the Military Medal.

Church, John William, Lieutenant Hertfordshire Regiment, eldest son of Sir William Church, Bt., K.C.B., killed on March 30th. He was educated at Harrow and University College, Oxford, and graduated with honours. He was called to the Bar in 1903 and served three years under the Colonial Office as District Commissioner on the Gold Coast. He enlisted in the Public Schools Battalion, Middlesex Regiment, in August, 1914, and received his commission in the Herts Regiment on March 1st, 1915. He served as assistant adjutant and acting captain in 1916-17, and joined his regiment at the front in August, 1917. He is survived by his widow and three daughters.

Craigmile, Alexander Murray, M.C., Captain Rifle Brigade, eldest son of Dr. Craigmile of Wallacey, killed March 29th,

aged 23. He was educated at Sedbergh, where he was in the fifteen and the eleven, and at King's College, Cambridge; got his commission on November 28th, 1914; was wounded in May, 1915; returned to the front in November, 1915, and got the Military Cross in October, 1917.

Cummins, Fenton King, Captain Connaught Rangers, youngest son of Professor Ashley Cummins of Cork, killed March 21st, aged 20. He was educated at Cheltenham College, was gazetted from Sandhurst in August, 1915, had been mentioned in dispatches, and got his company in March, 1918. His brother, Lieutenant Harry Jackson Cummins, 5th Gurkhas, was killed in Gallipoli in August, 1915, and four other brothers are now serving.

Featherstone, William Davies, M.C., Lieutenant R.F.A., younger son of Dr. W. B. Featherstone of Erdington, Birmingham, killed March 23rd, aged 22.

Gemmell, Stuart Stirling, Second Lieutenant Cameron Highlanders, youngest son of Dr. John E. Gemmell of Liverpool, killed March 21st, aged 19. He was educated at Uppingham, got his commission through the Cambridge Cadet Corps in August, 1917, and went to the front in September.

Gordon, Cecil Philip George, Captain South Staffordshire Regiment, only son of Colonel P. C. H. Gordon, R.A.M.C., accidentally killed while flying in Gloucestershire, March 21st, aged 24. He got his first commission on October 10th, 1914.

Gough, John Noel, Lieutenant R.F.A., son of Dr. Gough, medical officer of health of Northwich, Cheshire, killed recently. He was educated at King's School, Canterbury, whence he got a leaving exhibition to Trinity College, Cambridge, but took a commission in February, 1917. His brother, Lieutenant George Gough, was killed a few months ago in Palestine.

Gray, Edward J., Second Lieutenant Rifle Brigade, youngest son of Dr. Alan Gray of Cambridge, killed March 31st. He was born in 1898, educated at Winchester, where he was senior commoner prefect, and gained an exhibition at Trinity College, Cambridge, in December, 1915, but did not go into residence. He got a commission in January, 1917, and went to the front last June.

Hamer, John, Second Lieutenant K.S.L.I., killed on March 22nd, elder son of Dr. W. H. Hamer, M.O.H. for the County of London. He was born in 1897, and educated at University College School, Hampstead, where he held an entrance scholarship, and on the results of the London Matriculation was awarded the Horton Smith scholarship. He was in the first fifteen at the school 1914-16, and captain of the school in 1916-17, and gained an open scholarship in science at Christ's College, Cambridge.

Holmes, T. G., Second Lieutenant R.F.A., younger son of Dr. Holmes of Cheltenham, killed March 27th, aged 19. He was educated at Cheltenham College and Woolwich, and went to the front only seven weeks ago.

Hoops, H. A. M., Second Lieutenant Royal Irish Fusiliers, attached Royal Irish Rifles, son of Dr. H. L. Hoops of Cardiff, reported to have been killed, aged 21. Prior to joining the Officers' Training Corps he was serving his articles with an accountant at Cardiff. His brother is serving with the Royal Welsh Fusiliers.

Kenny, Hilary, Lieutenant Royal Naval Division, only son of the late Mr. A. S. Kenny, F.R.C.S., killed March 25th. He enlisted in the R.N.D., served in Gallipoli, and got his commission in the autumn of 1917.

Mackay, Ian, Captain Cameron Highlanders, eldest son of Dr. William Mackay of Craigmonie, Inverness, killed March 28th. He became lieutenant in the 4th Territorial battalion of his regiment on March 31st, 1913.

Newington, Percy W., Lieutenant East Kent Regiment, the Buffs, son of Dr. Newington of Edenbridge, killed March 21st, aged 20. He was educated at Epsom, passed into Sandhurst in July, 1915, got his commission in April, 1916, and went to France in July of the same year. He served through the battle of the Somme in 1916, and was promoted to lieutenant last October.

Spurway, Douglas, Captain Yorkshire Regiment, son of Dr. John Spurway of Brondesbury, killed in action on March 22nd, in his twenty-third year. He was educated at Bridgnorth Grammar School and St. Bartholomew's Hospital, and entered with a scholarship in October, 1914. In the following July, having passed his first professional examination, he joined the University of London O.T.C., and in two weeks obtained a commission in the 4th Battalion Yorkshire Regiment. He took part in the battles on the Somme, at Arras, and at Passchendaele Ridge, and was mentioned in dispatches in connexion with the latter. He was a great favourite at his school and with his fellow officers.

Watson, O. C. Spencer, Lieut.-Colonel King's Own Yorkshire Light Infantry, youngest son of the late Mr. W. Spencer Watson, killed March 28th. He was educated at St. Paul's School, and got his commission in the K.O.Y.L.I. in 1897. He served in the Tirah campaign of 1897-98, when he was dangerously wounded (medal and two clasps), and in China in 1900 (medal). He was invalided in 1904. He joined the 1st County of London Yeomanry in 1910, and served with them in Egypt and Gallipoli. He was promoted to major, and rejoined the K.O.Y.L.I., and went with them to France early in 1917, was dangerously wounded at Bullecourt in May, 1917, and received the D.S.O. He returned to the front last January, and was shortly afterwards promoted to lieutenant-colonel.

Wegg, Hugh Neville, Captain Middlesex Regiment, younger son of the late Dr. William Wegg, killed March 25th, aged 36. He got his commission in 1914, and became lieutenant on February 13th, 1915.

Whitehouse, John Luther Glendinning, Lieutenant R.E., only son of the late Dr. John Whitehouse, of the Scottish Church Mission in Rajputana, killed March 23rd, aged 20.
Wright, John Reginald Norrish, Cadet R.N., son of Dr. Wright, of Romford, Essex, died at the Royal Naval College, Osborne, April 5th.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

THE following is a continuation from p. 440 of our last issue of the particulars of acts of conspicuous gallantry and devotion to duty for which the decorations announced in the BRITISH MEDICAL JOURNAL, December 1st, 1917, p. 733, were conferred:

Military Cross.

Captain William Norman Abbott, N.Z.A.M.C.

He was untiring in his efforts in attending to the wounded under heavy fire during an attack. He worked without rest for seventy-two hours, and set a magnificent example to all.

Captain Douglas Lewis Barlow, A.A.M.C.

During an attack he advanced with the battalion, established his aid post, and dressed the wounded and assisted in their removal under constant shelling. Owing to casualties among bearers he was cut off from the ambulance clearing post for several hours, and it was mainly owing to his exertions that the wounded received attention and shelter during this period.

Captain Charles Henry Brennan, R.A.M.C.(S.R.).

He led his bearers fearlessly through heavy shell fire, and made a most valuable reconnaissance beyond the regimental aid post to find out if there were any wounded lying out. Though blown up and gassed, he remained at duty, setting a magnificent example to all.

Captain John Harold Balfour Brown, A.A.M.C.

When in charge of the forward line of evacuation for eight hours after his commanding officer was wounded, his reconnoitring of ambulance posts and regimental aid posts through the area of shell fire was of great assistance in controlling the evacuation. He supervised the loading of wounded into horse ambulances and organized the line of bearers and prisoners, and it was due to his action that great congestion was prevented.

Temporary Lieutenant (temporary Captain) Raymond John Clausen, R.A.M.C.

He worked continuously for forty-eight hours directing the stretcher-bearers and attending to the wounded under continuous shell fire. His cool courage and indomitable energy inspired his men and helped to save many lives.

Captain George Crawshaw, R.A.M.C.

His aid post was twice blown up, but he continued at his work in the open, attending to the wounded under heavy fire with utter disregard of his own safety. He set a magnificent example of courage and devotion to duty.

Temporary Captain Douglas Erith Derry, R.A.M.C.

While he was posting stretcher-bearers the locality was very heavily shelled, and many men were wounded, but he succeeded in dressing and removing them all under heavy fire. Later, in a small dressing station, when the shelters were hit and damaged by shell fire, he showed a splendid example to all by his coolness and resource.

Temporary Captain Thomas Duncan, R.A.M.C.

Though he was wounded on the way up to the line before an attack, he refused to go back, and carried out his duties under most difficult conditions, though suffering considerable pain, throughout the operation. He was again wounded, but continued at work until ordered to have his wounds attended to.

Captain Fred, Ellis, R.A.M.C.

He was in charge of stretcher-bearers during an action, and owing to his fearless and capable handling of his men the evacuation of the wounded was carried out with great success and rapidity. He remained in the open for long periods superintending the work. His disregard of danger and devotion to duty were of the highest order.

Temporary Captain Andrew Gaston, R.A.M.C.

During an attack he was untiring in his efforts to attend to the wounded under heavy shell fire, and personally brought in many wounded men, often dressing their wounds first in the open. His courage inspired all the wounded with confidence, and proved the finest example to his stretcher-bearers.

Captain Stuart Galloway Gibson, A.A.M.C.

While he was in charge of a detachment at a loading post the enemy opened a heavy bombardment. Though nearly all the shelters were demolished, he continued at his work of removing casualties throughout intense shelling. He set a splendid example of courage and devotion to duty.

Captain William Evans Graham, R.A.M.C.

By his utter disregard of danger when in charge of stretcher-bearers he set a splendid example to his men, and carried out the evacuation of the wounded under heavy and continuous shell fire until he was severely wounded.

Temporary Captain John Lewis Anderton Grant, R.A.M.C.

He conducted a number of stretcher squads through very heavy shell fire to the aid posts after they had previously failed to get through. Two bearers were killed and three wounded, but by his gallant action over forty stretcher cases were got to safety. Later, he personally conducted squads to these aid posts under similar circumstances.

Temporary Lieutenant Henry John Henderson, R.A.M.C.

He established his aid post within 300 yards of the enemy's position, and dressed and evacuated cases in the open. It was due to his splendid example, cheerfulness and courage, that a great number of lives were saved.

Captain Charles Edward Kynaston Herapath, R.A.M.C.

During two attacks he was in charge of the evacuation of the wounded from the regimental aid posts. On both occasions he moved about from post to post under very heavy shell fire, encouraging the stretcher-bearers and organizing the evacuation. It was largely owing to his conduct and example that 1,000 cases were got away successfully.

Captain Frederick William Kemp, N.Z.A.M.C.

He was untiring in his efforts in attending to the wounded under heavy fire, during an attack. He worked without rest for seventy-two hours, and set a magnificent example to all.

Captain David Mackie, R.A.M.C.(S.R.).

When in charge of a line of evacuation, for four days he worked continuously in the open, going through heavy barrages.

Temporary Captain John Charsley Mackwood, R.A.M.C.

He attended to the wounded of eleven units in the open under heavy shell fire, working single-handed for several days. His self-sacrificing devotion to duty and his thoughtfulness and care of the wounded were beyond all praise.

Temporary Captain William Strelley Martin, R.A.M.C.

He led his bearers during seven days' operations through the most intense shelling with infinite resource and regardless of personal safety. It was due to his masterly organization and example that the wounded were collected so promptly.

Temporary Captain John Louis Menzies, R.A.M.C.

He worked continuously for thirty-six hours dressing and collecting wounded in the open under shell fire. When forced to take refuge, his shelter was blown in and he himself badly shaken and only saved by his steel helmet. He remained at his post, however, until relieved in the ordinary course.

Temporary Captain James Bertram Mitton, R.A.M.C.

When in charge of stretcher-bearers, by his courage and example he was able to get many wounded men away. The district was almost continuously under heavy shell fire and the roads were in a very bad condition, but he overcame all difficulties in a most praiseworthy manner and set a splendid example of courage and self-sacrifice.

Temporary Captain John Henry Morris-Jones, R.A.M.C.

He carried on his duties at his aid post during an enemy attack under very heavy fire. He also visited wounded men who were lying out in the heaviest of the fire, and went up to the front line to attend to the wounded. He showed total disregard of his own safety, and encouraged all by his cheerful and courageous demeanour.

Temporary Captain Joseph Herbert Porter, R.A.M.C.

He was in charge of the divisional collecting post during an action, and by his example and thoroughness did much to encourage all ranks in the discharge of their duties. He went forward in charge of bearers, and by his untiring energy succeeded in getting his communications re-established in the face of great difficulties.

Temporary Captain Norman Pallister Pritchard, R.A.M.C.

When in charge of his aid post during operations, it was entirely owing to his untiring care of the wounded and exertion in marshalling stretcher-bearers that all were eventually evacuated and lives saved thereby. Most of his work was done in the open under observed machine-gun fire.

Captain James Purdie, R.A.M.C.(S.R.).

When he was informed that there were a number of wounded in the front line during an action, he at once went forward with his stretcher-bearers, under heavy fire, and remained in the front line dressing and collecting the wounded until all were cleared. He set a fine example of courage and devotion to duty.

Captain James Rafter, R.A.M.C.(S.R.).

By his splendidly sustained effort in dressing wounded and organizing stretcher-bearers in the open under heavy shell fire during four days' operations without relief he undoubtedly saved many lives and much suffering.

Captain Stanley Arthur Railton, A.A.M.C.

During a very heavy barrage and an enemy counter attack he attended to the wounded in the open, with complete disregard for his own safety. His courage and coolness in carrying on his work under such conditions resulted in the saving of many lives.

Temporary Captain Alan Randle, R.A.M.C.

He went forward during an action and personally cleared the battlefield of wounded, evacuating 120 cases in two hours under heavy shell fire. He showed great courage when casualties were caused by a bombardment during a relief.

Captain Edmund Lewis Reid, S.A.M.C.

He accompanied the battalion in the attack and attended to the wounded with magnificent fearlessness under heavy fire in the open. He visited and attended to cases in the front line, and it was largely due to his efforts that the wounded were quickly dressed and cleared. His courageous conduct saved many lives.

Captain Hugh Arthur Sandiford, M.B., R.A.M.C.

He took up a position immediately behind the front line during an attack and dressed the wounded in the open. He displayed great coolness and gallantry under heavy artillery fire, working in an exposed position for forty-eight hours.

Temporary Captain William Logan Scott, R.A.M.C.

He worked untiringly, attending to the wounded in the open under heavy fire during an engagement, and showed splendid courage and resource.

Captain Frederic Battinson Smith, R.A.M.C.

He worked in a shell hole, attending to the wounded, throughout a very heavy bombardment. At night he frequently went out into No Man's Land with parties to bring in the wounded. He showed splendid courage and fearlessness.

Captain Edwin Cyril Widmerpoole Starling, R.A.M.C.(S.R.).

He remained day and night at his post under continuous shell fire, and was untiring in his work on behalf of the wounded, to whom his unremitting care and unflinching calmness was the greatest comfort and assistance. He set a splendid example of courage and self-sacrifice.

Temporary Captain John Glyndor Treharne Thomas, R.A.M.C.

He established a forward dressing station in an advanced position during an action, and, though heavily shelled throughout the whole day, stuck to his post in a most courageous manner, and undoubtedly saved the lives of many men. He organized search parties, and himself carried in a number of badly wounded men under rifle and machine-gun fire.

Temporary Captain John Aylmer Tippet, R.A.M.C.

When his dressing station was blown in and nearly all the occupants killed, although much shaken, he immediately organized a new station, and for eight hours dressed and tended the wounded without rest. Later, when the battalion moved forward, he went through a heavy barrage to the new dressing station and worked continuously for six hours. During five days he had practically no rest, and dealt with some 300 casualties.

Captain Adam Annand Turner, R.A.M.C.

He remained at duty for forty-eight hours under fire and without rest, and succeeded in getting all the wounded away rapidly from the aid posts and forward areas in spite of heavy enemy barrages. He set his men a splendid example of fearlessness and devotion to duty.

Temporary Captain John Wilfred Watthews, R.A.M.C.

His evacuation of the wounded during and after attack was carried out with wonderful organization and skill. He worked continuously for forty-eight hours attending to the wounded under hostile shell fire.

Captain Harry Whitaker, R.A.M.C.

During an action he went forward and, in spite of heavy shell and machine-gun fire, searched out and dressed the wounded in the most advanced positions. When a counter-attack developed he refused to leave his post until all the wounded had been removed. His courage and devotion to duty were an inspiration to all ranks.

Temporary Captain Henry Dewi Hampton Willis-Bund, R.A.M.C.

He was in charge of a dressing station which was destroyed by shell fire. Though rendered unconscious, he continued to attend to the wounded in the open when he recovered, accompanied the battalion into action, and remained at duty for forty-eight hours. He showed the greatest courage and devotion to duty.

Captain Eric William Beresford Woods, A.A.M.C.

For several days he worked at his aid post under very heavy shell fire, attending to all stretcher cases in the open with great courage and complete disregard of danger. His untiring energy and organization saved many lives.

OPERATIONS IN PALESTINE.

The following medical officers are included in a list of awards for distinguished service in the field in connexion with military operations culminating in the capture of Jerusalem, published in a special Supplement to the *London Gazette* issued on April 11th:

To be C.M.G.

Colonel Richard H. Luce, C.B., V.D.

Awarded the D.S.O.

Colonel Evelyn J. R. Evatt, R.A.M.C.

Lieut.-Colonels (temporary Colonels): George A. T. Bray, R.A.M.C., Ernest B. Dowsett, R.A.M.C.

Temporary Lieut.-Colonel Henry Wade, R.A.M.C.

Majors (temporary Lieut.-Colonels): Robert J. Cahill, R.A.M.C., Matthew Dunning, R.A.M.C., Hugh Richardson, R.A.M.C.

Temporary Major James J. Abraham, R.A.M.C.

Captain (acting Lieut.-Colonel) Ernest C. Lambkin, R.A.M.C.

Awarded the Military Cross.

Captains: Phillip S. Martin, R.A.M.C., Archibald B. Mitchell, R.A.M.C., James M. Mitchell, R.A.M.C.

Temporary Captain Gerald F. Bird, R.A.M.C.

THE King of the Belgians has conferred the decorations of Chevalier of the Ordre de Leopold and the Croix de Guerre upon Captain Robert G. Martyn, R.A.M.C.(S.R.), for distinguished services rendered during the course of the campaign.

NOTES.**SPECTACLES FOR SOLDIERS.**

SINCE the paragraph on spectacles for soldiers was published on April 6th, p. 406, we have received a copy of Army Council Instruction 1371 of 1917, which is as follows:

- (a) No simple spherical lens will be supplied of a less strength than 1.00 dioptré, or of a greater strength than 18.00 dioptries.
- (b) No simple cylindrical lens will be supplied of a less strength than 1.00 dioptré, or of a greater strength than 6.00 dioptries.
- (c) No spherocylindrical lens will be supplied having before or after transposition:
 - (i) One of its component parts less than 0.50 dioptré and the other component part less than 1.00 dioptré.
 - (ii) A combined strength of greater than 18.00 dioptries.

or

- (iii) A cylindrical strength greater than 6.00 dioptries.
- (d) No spherocylindrical lens will be supplied with a concave spherical surface and a convex cylindrical surface.
- (e) No greater dioptré lenses will be supplied above 3.00 dioptries, and no half dioptré lenses above 6.00 dioptries.

As will be seen, the Order permits the supply of spherocylindrical lens, one of the component parts of which is half a dioptré, and therefore so far meets our suggestion. We believe that it would be politic to correct the smaller errors of refraction in all men engaged in clerical work for long hours.

Correspondence.**PRIMARY SUTURE OF WAR WOUNDS.**

SIR,—In view of the fact that the names of others than a consultant surgeon are mentioned in Sir Anthony Bowlby's paper which appeared in the *BRITISH MEDICAL JOURNAL* of March 23rd, I feel it is only just, considering the knowledge of the facts which I possess, that credit and prominence should be given to the work of surgeons like Milligan, Charles, Lockwood, Roberts, Tabuteau, the Andersons, and others, who in 1914 and 1915 were laying the foundation, in an unostentatious way, of the recent work of which Sir Anthony writes. I am sure that the surgeons quoted in Sir Anthony Bowlby's paper would not wish that mention should be made of them alone.

I wish to point out that successful excision and suture of wounds of soft parts preceded and justified the application of the procedure to wounds of the knee-joint, head, chest, etc. It was the natural sequence. More than two years ago successful primary closure of fracture cases was being carried out.

Many of the names I have mentioned above are attached to articles describing work and results the excellence of which, in the early days of the war, was realized only by those who experienced them. The technique introduced then has stood the test of time, and is now, thanks to General Bowlby and others, being more widely appreciated. —I am, etc.,

H. M. W. GRAY,

France, March 31st.

Temporary Colonel A.M.S.,
Consultant Surgeon.

EPIDEMIC OF OBSCURE ORIGIN—POSSIBLY BOTULISM.

SIR,—I desire to call the attention of your readers to a series of unusual cases which have been occurring in and around the Sheffield district during the last few weeks so as to constitute a small epidemic. The characteristic features of the ten cases I have so far seen are briefly as follows: Acute and profound asthenia, amounting in some cases to complete disablement; drowsiness and apathy, sometimes with much delirium; and, also, various combinations of cranial nerve palsies, chiefly the oculo-motor nerves and the facials. In three of the cases there is facial diplegia, in two unilateral facial palsy. Nystagmus is an almost constant symptom. In some the clinical picture is that of a meningitis, but they recover instead of getting worse; in others profound drowsiness and asthenia are the most prominent symptoms.

Most of the cases have been in adults. No two have occurred in the same house, but in three instances two cases have lived quite near to each other. It is too early to hazard an opinion as to the exact nature or origin of these cases, but the symptoms present a similarity to those seen in certain outbreaks of botulism, due to the consumption of food infected by *B. botulini*. A reference to available descriptions of this disease is suggestive, and investigations are proceeding on these lines. It emphasizes the importance, should fresh cases arise, of making a detailed inquiry, as early as possible, concerning the foods taken by the patient prior to his illness. Otherwise, in a few days, such details are either unobtainable from the patient, owing to his condition, or forgotten by the friends. It seems desirable to make this preliminary statement in the hope of ascertaining whether similar cases, either isolated or in groups, have been met with elsewhere.—I am, etc.,

Sheffield, April 14th.

ARTHUR J. HALL.

THE VALUE OF THE WASSERMANN TEST.

SIR,—The memorandum in your issue of April 13th, by Dr. J. S. Robertson, contains warnings which merit more than a passing notice. Not only some of our profession, but numbers of the laity are lulled into a sense of security by a "negative" Wassermann reaction. It is not uncommon for men who have had syphilis and have discontinued treatment to undergo a Wassermann test without reference to their medical adviser. If the report is negative, they believe that they are "cured" and are liable to neglect fresh symptoms. I have recently had such a case, in which a negative reaction was reported to the patient (not to his doctor), and consequently no advice was sought

for many weeks after fresh syphilitic lesions developed. It seems to me very important that the public should be disabused of their faith in a negative blood reaction to this test.—I am, etc.,

London, W., April 15th.

J. B. LAWFOED.

UNIVERSITY REPRESENTATION IN PARLIAMENT.

SIR,—Like probably many others, I have received a circular from a self-constituted committee, which seems desirous to appropriate for a Conservative or Unionist the seat in Parliament given to some seven universities. May I venture to urge my co-electors in all these universities to set their faces like steel against the introduction of politics, especially of a kind now becoming rapidly obsolete?

That some united action is necessary is apparent to all graduates, but I would voice a wish that what we at this juncture require—after a compromise between the several universities concerned and the professions involved—is a candidate or candidates keen on social questions, whether educational, health, or other, who knows his subject and who we can support—financially, if necessary—at the election, and afterwards in carrying out his task.

Will those in authority in these universities, representative of the professions involved, wake up and give the graduates an opportunity to crystallize their opinions and actions before it is too late?—I am, etc.,

Hove, April 11th.

E. ROWLAND FOTHERGILL, M.B.

Obituary.

GUY ELLISTON,

FINANCIAL SECRETARY AND BUSINESS MANAGER OF THE BRITISH
MEDICAL ASSOCIATION.

THE deep regret with which we announce the death, at the age of 46, of Mr. Guy Elliston will be shared by all members of the Association, but especially by those who have had opportunity of knowing the work he has unobtrusively done for it during the last nineteen years. He had not been in robust health for some time, and an attack of pneumonia proved fatal on April 13th after a few days' illness.

Guy Elliston was the third son of the late Dr. W. A. Elliston, who was president of the British Medical Association when it held its annual meeting in Ipswich in 1900. He was educated at Ipswich School, and entered upon a business career in Liverpool in 1888, where he was concerned in initiating a direct steamship service between Manchester and Paris. In 1897 he joined the staff of the *Weekly Sun*, and in the following year became manager of the *Naval and Military Magazine* and the *Public Health Magazine*. He joined the 1st Lancashire Artillery Volunteers in 1891, retiring when senior captain in 1897.

Mr. Elliston became Assistant Secretary to the British Medical Association in 1899, and succeeded Mr. Francis Fewke as General Secretary in 1902. The reconstitution of the Association in 1902 and the great expansion of its medico-political work led to the creation of the office of Medical Secretary, and Mr. Elliston's sphere of duty was defined as that of Financial Secretary and Business Manager. His interest in everything concerning the welfare of the Association never flagged. He was always diligent in supplying information required by the Council or its Committees, and did not spare himself in procuring and setting it out. The better he was known the higher became the opinion of his competence in his special sphere of duties. He was ever anxious also to assist individual members of the Association, and he won amongst them many friends who appreciated his qualities as a man and valued his intimate knowledge of the business side of professional life.

The financial position of the Association in 1902 was very satisfactory; it owned the freehold of its house in the Strand and possessed a considerable sum in investments. The policy of building larger and more convenient offices having been accepted in principle, plans were approved as the result of a public competition and the work was begun in 1907. Mr. Elliston arranged temporary offices in Catherine Street, where the work was carried on for two years. In 1908 the new offices were ready for occupation and the expenditure on the whole transaction was being defrayed at a satisfactory rate.

The financial situation was seriously altered for the worse by the introduction of the Insurance Act in 1911, entailing on the Association a large expenditure in its struggle to maintain the just claims of the profession. For some years the position caused anxiety to those responsible for the financial affairs of the Association, and especially to the Treasurer, Dr. Rayner, and his executive officer, Mr. Elliston. The wise and careful policy followed was rewarded by steady improvement. The favourable course was interrupted by the outbreak of the war and the disturbance it produced in all business affairs, not least in those in any way concerned with printing and publishing; prices went up for everything, including postage, a serious matter to an Association which issues a weekly journal by post, as well as many other documents, to some twenty-four thousand members. The foresight and prompt decision displayed by Mr. Elliston as each fresh difficulty arose were of the greatest value in enabling the Association to maintain its work while safeguarding its funds. His action has again and again received marks of approval from the Council and deserves like recognition from every member.

The preliminary arrangements for the annual meetings of the Association, and for the exhibition held during each, were in the hands of Mr. Elliston; and Dr. Collier, President of the Association when it met at Oxford in 1904, recalls in a short note the invaluable help Mr. Elliston so readily gave to him. The local committees in other centres will be ready to bear testimony to the same effect.

The Workmen's Compensation Act of 1906 raised many questions which seriously concerned the medical profession, and the need for insurance against the risks which arose under it was in every one's mind. It was felt that steps should be taken to meet the special needs of the profession, but it was found that the British Medical Association could not under its constitution undertake the work. The *Lancet* and the *BRITISH MEDICAL JOURNAL*, acting together, formed a committee which established the Medical Insurance Agency, with the late Dr. Radcliffe Crocker as Chairman, and Mr. Guy Elliston as Secretary and Agent. The work of the agency grew rapidly, and it was extended to include life assurance, motor car insurance, and policies covering other risks of professional life. It had been resolved at the inception of the agency that special concessions should be made to policy holders, and that any surplus should be used to make contributions to existing medical charities. At the half-yearly meeting of the committee last November it was reported that since the agency was established the insured had received £6,500 by way of direct benefit, and at the same time had the satisfaction of knowing that substantial contributions were being made to the funds of medical charities. Down to the end of 1916 the agency had thus distributed £2,405; at the end of 1917 the amount had risen to £3,405. The funds chiefly benefited have been the Royal Medical Benevolent Fund and the Guild, the Epsom College Benevolent Fund, and the Royal Medical Benevolent Fund of Ireland. Last year a sum of £1,000 was distributed, including a special contribution made to the War Emergency Fund of the Royal Medical Benevolent Fund. Dr. Haslip, who in 1909 succeeded Dr. Radcliffe Crocker as chairman of the committee, desires us to say that in his judgement the success of the agency has been in a large measure due to the judicious and energetic manner in which Mr. Elliston conducted its affairs.

Mr. Elliston leaves a widow and four daughters, and with them much sympathy is felt. Three of his brothers are at present serving with the armies abroad.

Dr. EDWIN RAYNER, who was treasurer of the British Medical Association from 1907 to 1915, has sent us the following tribute to Mr. Elliston's memory:

Since the last issue of the *JOURNAL* the British Medical Association has sustained a serious loss through the death of Mr. Guy Elliston, its Financial Secretary and Business Manager. His illness was not generally known to the members, and it was only in the later part of last week that complications supervened causing grave anxiety to those associated with the case. On Friday there seemed some slight improvement, but the reports said that he was very weak. This weakness seems to have rapidly increased, and he passed away on Saturday morning. A more careful,

trustworthy, and conscientious official no society every had. Never, especially of late years, blessed with robust health, he always considered the welfare of the Association far before his own health and pleasure. A month or so ago he was too unwell to come to the office for a time, and had he not interrupted his convalescence by coming to the office and so exposing himself to the continual piercing winds we might not have had to deplore his loss. I have been closely associated with him for many years in the work of the Association, and often in anxious circumstances, as when our overdraft at the bank increased and attained the sum of £55,000. It was finally cleared off at the beginning of 1917, and this happy condition was partly due to the industry and foresight of our Financial Secretary. Personally I have been associated with him for ten years, and I greatly deplore his loss. He was proud of the Association, and those members of the Association with whom he came most in contact were proud of him.

Dr. HASLIP, who has been Treasurer of the Association during the last two years, and Chairman of the Committee of the Medical Insurance Agency since 1909, adds the following personal tribute:

The death of Mr. Elliston, our Financial Secretary, must have come as a great shock to many of our members, as it was to myself, for the last report received of his illness was so favourable that we had hoped he was out of danger. However, this was not to be, and we have all to mourn a loyal colleague and a most devoted and faithful officer of the Association. My predecessor, Dr. Rayner, can speak of Mr. Elliston's services during the strain on the finances of the Association by the rebuilding of our premises and in the period after the introduction of the Insurance Act. Although my knowledge with regard to his business capacities extends over the same period, I can write better of my further appreciation during the time I have been practically in daily contact with him; I can substantiate all Dr. Rayner has said, for it has been due to his foresight and knowledge that we have been able to cope with the difficulties which have constantly recurred during this period of war; they have been very perplexing and worrying. When we remember the rise in the cost of printing, the great increase in the price of paper and the difficulty in obtaining an adequate supply, and the fact that our interests have been twice affected by enemy action—involving on the last occasion the destruction of a considerable quantity of paper—the anxieties caused to our late Business Manager will be understood.

As to Mr. Elliston's services to the Medical Insurance Agency, I have no hesitation in saying that it has been entirely due to him that so great a success has been achieved. Started from a small beginning and with modest expectations, we were able in the early years to give £50 to medical benevolent funds, and were highly gratified by this result; but last year, 1917, the committee was able to devote the sum of £1,000 to charitable purposes; the early prognostications of our secretary were thus confirmed, and I know that this gave him great satisfaction, for he saw that an annual contribution such as this would become powerful in helping to bring about the proper co-operation of our various medical charities, which was the great object of his ambition, for, being a practical business man, he knew that by this arrangement further benefit would be derived by the profession. I consider that this great success will always be a memorial of his services to the profession.

Personally I know I have lost a true friend and colleague and one it will be very difficult to replace. By his death we of the Association I am convinced have not only lost an officer who was a courteous gentleman, always ready to give his advice and assistance to members, but a good financial adviser possessing great foresight and sound sagacity. We shall have every reason to mourn the loss of Guy Elliston.

The EDITOR, who has been closely associated with Mr. Elliston throughout the whole of his service with the Association, begs leave to add a few personal words. Elliston did not appear at his best on public occasions; it was necessary to watch his work from day to day to know how valuable his services were to the Association, and with what honesty and zeal he gave his best to it through nineteen years, in which he encountered and surmounted

many difficulties. He was thorough and conscientious in all his work. He had so intimate a knowledge of finance, and moved so easily among figures that he did not always find it easy to understand the difficulties of the less expert. For this reason his first presentation of a new subject might fail to carry conviction, but discussion showed that the points were quite clear in his own mind, and that all that was needed was a fuller statement in which assumptions that had seemed to him obviously true were set out and explained. He was always looking ahead, and again and again, during the last four years especially, his forecast was justified by the event. A more loyal colleague never breathed.

The funeral took place at Ipswich on April 17th. The British Medical Association was represented by the Chairman (Dr. J. R. Staddon) and the Honorary Secretary (Dr. F. Fowler Ward) of the South Suffolk Division, and by Dr. James Neal, the Deputy Medical Secretary. Amongst the floral tributes was a wreath from Dr. G. E. Haslip, the Honorary Treasurer of the Association, another from the officers of the Medical Secretary's department and the BRITISH MEDICAL JOURNAL, and a third from the clerical and printing staffs of the Association.

W. M. CROWFOOT, M.B., F.R.C.S. Eng.,

CONSULTING SURGEON TO THE BECCLES HOSPITAL.

THE death of Dr. William Miller Crowfoot, of Beccles, on April 6th, at the age of 80, removes one of the most distinguished members of the medical profession in East Anglia. For more than a century the Crowfoots of Beccles, father and son, have been held in the highest esteem by their professional brethren far and near.

Dr. William Crowfoot received his medical education at St. Bartholomew's Hospital, where he had a distinguished career, winning many medals and scholarships at the University of London. After receiving the qualifications M.R.C.S. and L.S.A. in 1858, and the M.B. degree in the following year, he joined his father in practice. In 1890 he was elected a Fellow of the Royal College of Surgeons. Dr. Crowfoot took an active part in local affairs. He was a keen supporter of the volunteer movement of 1860, retiring with the rank of honorary lieutenant-colonel, and was a justice of the peace for the County of Suffolk. Dr. Michael Beverley, who was associated with Dr. Crowfoot professionally for more than fifty years, writes of his popularity in the medical circle at Norwich, and of his high social and scientific qualities. To the proceedings of medical meetings there he often contributed valuable papers, and his address as president of the East Anglian Branch of the British Medical Association many years ago was a signal success. Dr. Crowfoot was an enthusiastic naturalist, with a special leaning towards botany, and he took a keen interest in archaeology. The funeral took place on April 10th.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on April 11th, when Sir George Makins, G.C.M.G., C.B., President, was in the chair.

It was decided not this year to present a report to the Fellows and Members, nor to hold the annual meeting of Fellows and Members.

The subject for the Jacksonian Prize for the year 1919 is the investigation and treatment of injuries of the thorax received in war. The John Tomes Prize for 1915-17 was awarded to Mr. Joseph George Turner, Fellow and Licentiate in Dental Surgery of the College, for his work on the subject of dental pathology. Miss Edith Marjorie Rooke, of the London School of Medicine for Women, was appointed to the Begley Studentship.

The following Members of twenty years' standing were elected Fellows: Sir Alan Reeve Manby, M.V.O., Colonel Sir Robert Jones, C.B., A.M.S., Inspector of Military Orthopaedics.

THE Local Government Board has issued an order empowering county councils and borough councils to arrange for the provision of serum for the treatment of cases, or suspected cases, of cerebro-spinal fever, together with the necessary apparatus for administration, and for the examination of suspected cases and contacts. The order applies to every administrative borough in England and Wales, and is in force as from April 1st, 1918. Its object is to secure the prompt gratuitous provision of antimeningococcus serum for the use of medical practitioners in each area.

Medical News.

Dr. G. F. SYDENHAM, of Dulverton, Somerset, has been appointed a Justice of the Peace for Somerset.

THE bill of the Decimal Association for a decimal coinage in this country has been approved by the Associated Chambers of Commerce, and will be introduced into the House of Lords by Lord Southworth.

MAJOR SIR ROBERT ARMSTRONG-JONES, R.A.M.C., will read a paper on mental effects of the war and their lesson in social and medical reconstruction, at the Royal Society of Arts, John Street, Adelphi, on Wednesday, when Lord Sydenham will take the chair at 4.30 p.m. All interested in the subject are invited.

AT a meeting of the Edinburgh and Leith Medical War Committee, on April 10th, a resolution was adopted unanimously disapproving of the apparent intention of the Government in the new Military Service Bill to treat members of the medical profession on a different footing from other classes by making them liable for service to the age of 56 years. The resolution was approved at another meeting of medical practitioners in Edinburgh on April 12th.

AT a meeting of the Irish Committee on April 4th, Dr. Giusani in the chair, a resolution was unanimously passed offering the support of the committee to the Enniskillen Poor Law medical officers in their efforts to secure adequate salaries from their guardians. At a meeting of the Irish Medical Committee, presided over by Dr. E. C. Thompson, D.L., a resolution was passed expressing the sympathy of the meeting with the Enniskillen dispensary doctors who resigned their offices when the guardians had refused three applications to increase their salaries.

DR. ADDISON, Minister of Reconstruction, in reply to a deputation from the Joint Standing Committee of Industrial Women's Organizations and the Labour Party, urging the immediate establishment of a Ministry of Health, stated that just before Easter he concluded the negotiations in which he had been engaged for some months at the Prime Minister's request. As soon as the national crisis became less acute he hoped to present his proposals to the Government. If it were decided before long to establish a Ministry of Health, he anticipated that the measure which Parliament would be asked to sanction would receive the whole-hearted approval of those whom the deputation represented.

THE reports as to the prevalence of plague in Northern China have received explanation in a letter published in the *Times* from its Peking correspondent. It appears that in December information was received from missionaries in the district of Mongolia immediately north of the Shansi Province of China that pneumonic plague had broken out. The fact was confirmed by foreign and Chinese doctors sent to the spot. The epidemic spread into the northern part of Shansi and finally to a point 150 miles south-west of Peking, where it was close to the Chengtai Peking-Hankow railways, but owing to the precautions taken by the railway authorities no cases occurred on either line, although the infection also spread eastward to a point 100 miles north of Peking. It is hoped that the worst is over, but no certainty can be felt that the infection may not be lighted up in other regions. The origin of the present outbreak is at present unknown, but it is thought to be associated with the marmots of the Mongolian plateau. In his volume of reports on the North Manchurian Plague Prevention Service, which has just reached this country, the director, Dr. Wu Lien-Teh, who is a Cambridge graduate and a London student, gives much interesting information. Writing on October 26th he was able to say that plague had then been absent from Manchuria and Northern China for the seventh year in succession; but he noted that there had been an outbreak of pneumonic plague in Kansu, on the Tibetan border, which, however, was easily dealt with. With the assistance of Dr. Ebersson, a graduate of Columbia University, who arrived in Manchuria in May, 1916, special investigations had been made in the research department at Harbin in the hope of discovering a serum for pneumonic and septicaemic plague. Dr. Ebersson reported his results in the *American Journal of Experimental Medicine* in a paper on the nature of plague proteotoxins, and in another on the production of active immunity to systemic plague. One of the articles in the volume points out that while pneumonic plague is most dangerous in winter bubonic plague is more prevalent in the warm weather, and the behaviour of the disease during the present summer will be watched with interest and some apprehension. The importance of the rat as disseminator of the disease is fully recognized.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediseera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

A VACANCY is announced for a medical referee under the Workmen's Compensation Act, 1906, for the Canterbury, Faversham, Ashford, and Tenterden and Cranbrook County Courts in Circuit No. 49. Applications to the Private Secretary, Home Office, by May 2nd.

ORAL SEPSIS.

MAJOR F. N. GRINLING, R.A.M.C.T.F. (Wolverhampton), writes that he has been struck, whilst acting as president of an invaliding board principally engaged in reviewing the cases of men already pensioned, by the large number invalided for neurasthenia, rheumatic and other affections, who were suffering from the effects of oral sepsis. In the majority of cases the documents give no evidence of previous recognition of this factor. This illustrates, he says, not only the inadequacy of dental treatment in the army, but also the futility of a National Insurance Act which makes no provision for such treatment.

J. G. H. writes to suggest that the frequency of pyorrhoea alveolaris amongst soldiers is due to the absence of fruit from their dietary.

THE VENEREAL DISEASES ACT, 1917.

In the King's Bench Division on April 16th an appeal was heard in a case stated by two of the justices of Cannock, Staffordshire, with reference to a conviction by them under the Venereal Diseases Act, 1917. It appears from the report in the *Times* that a handbill offering to give advice on the treatment of venereal disease in the name of the Curtis Medical Laboratory (Ltd.), of Hill Street, Birmingham, was found on October 11th, 1917, to be affixed to the inside wall of a public urinal at Cannock. The prosecution was taken against James Walker, Harry Key, and Fred. Waite—Walker being a director, Waite manager and secretary, and Harry Key a shareholder in the company, the three being the only persons present at the last annual meeting of the company. The magistrates stated that from the evidence before them it was proved to their satisfaction that the three defendants named all took an active part in carrying on the said business of the company, and that the said bill advertising the same was posted on their authority and with their knowledge and consent. The magistrates convicted, and fined Walker £25, Key £50, and Waite £50. The appeal was made on the ground that there was no evidence that any of the three defendants had either committed the offence or aided and abetted in its commission, and that there was no evidence that any of them took any part in the business of the company. Counsel for the respondents were not called on. Mr. Justice Darling, who delivered judgement, said that the magistrates were quite justified in coming to the conclusion they did. The three defendants had individually violated the provisions of the Act of Parliament. Mr. Justice Avory and Mr. Justice Atkin concurred, and the appeal was dismissed with costs.

THE CAPACITY OF THE BLADDER.

DR. W. JOBERNS (Wolverhampton) writes: A primipara on the third day complained of pain in the lower part of the abdomen, and said she had not passed any water during the day, though the bowels were moved the day before. A catheter was passed and five pints of urine drawn off. The quantity was carefully measured.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	0 4 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postea restante* letters addressed either in initials or numbers.

THE SELECTION OF ABDOMINAL CASES FOR OPERATION.

WITH REFERENCE TO A SERIES OF 200 OPERATIONS.

BY

OWEN RICHARDS, D.S.O., F.R.C.S.,
TEMPORARY COLONEL A.M.S.

At this stage of the war it is not worth while to give details of a series of cases essentially similar to others which have already been published. The value of early operation and the best technique are generally agreed on, and the percentage mortality is fairly constant. If it varies much from the average in any special collection of cases, the reason can usually be found in temporary and local conditions, which affect the time that the wounded take to reach hospital and the state in which they arrive there.

In a series of over 1,200 cases Wallace¹ found the rate of recovery to be 46 per cent. in all cases operated on, and 35 per cent. in those with wounds of the hollow viscera. In the present series the corresponding figures are 41.5 and 38 per cent. respectively.

"Successful" and "Profitable" Operations.

The percentage of patients who survive operation is, however, no real index of the value of treatment. In a large number of cases injuries are found which no surgery could cure; in others there are minor ones which would not have proved fatal even if they had been left alone. To count these as "failures" and "successes" respectively is unreasonable. In the first class of case we have failed to do what was in any case impossible; in the second our only success consists in not having killed the patient. Operation in both was unprofitable. The only kind of operation which is "profitable" as well as "successful" is one in which we find a fatal injury and cure it. These constitute the real successes.

The real failures are the cases in which the patient is wrongly classed as moribund when operation might have saved his life, and those in which a penetrating wound of the abdomen is not recognized as such until it is too late. Failures due to bad surgery are relatively rare, for the general level of surgical skill in the clearing stations is a high one. The difficulty lies rather in the selection of cases, and it is here, rather than in any point of technique, that most difference exists in the practice of individual surgeons.

Men who reckon every case "moribund" who has been wounded for more than twelve hours, or has a pulse of 120, will be able to show good statistical results. Those who operate on practically every living patient will waste much energy, and have a high death-rate—they will, however, save a few more lives.

The difficulty lies in determining the circumstances under which operation ceases as a rule to be worth while, even though it may yield an occasional success. This is important mainly for the sake of other patients. A hopeless abdominal case is only injured by operation in the sense that his life may be shortened by a few hours, while an exploration which proves unnecessary is rarely fatal. But every "unprofitable" operation means that time is wasted, and that other wounded have to wait longer. During an engagement, which is the time at which most cases have to be dealt with, this is a very serious matter. There may be in one station thirty or more cases waiting for operation, and developing sepsis and gangrene meanwhile. Every hour wasted makes the chances of all of them definitely worse. So that under these conditions any wrong selection has very far-reaching effects, for the inclusion of unsuitable cases may result in the loss of lives or limbs of other patients.

It is therefore worth while to consider what guidance can be got from the experience available. The present series is small, but it probably represents a fair average both as regards results and conditions.

Certain classes of injury may be at once ruled out. Wounds limited to the solid organs, with no progressive bleeding, and no large missile retained, do not usually need operation, and patients with other grave injuries of head, chest, or limbs are commonly unfit to stand it. In the vast majority of the remainder it can usually be

recognized that the abdomen is penetrated, but the nature and extent of the internal injury is almost always unknown.

In civil surgery the risks of a known injury or disease can to some extent be weighed against those of a set operation; but here both are unknown, and the abdomen is opened on the broad grounds that most men wounded in this part of the body die, but that some of them can be saved by operation. Whether operation is necessary or not can only be discovered by performing it, and if it is at all likely to be, exploration is fully justified.

Under these conditions we have to base our decision in each case on such facts as we can know. Practically these consist of the time which has elapsed since the injury, and the condition of the patient, of which the best index is the pulse.

Interval between Wound and Operation.

In this series the time which had passed since the injury was recorded in 164 cases; 120 were operated on within twenty-four hours, and 44 later. The recoveries in the early cases were 48 (40 per cent.), and in the later 19 (43 per cent.). This latter figure is remarkable, for there is usually a higher death-rate in late cases. Wallace in 79 cases operated on after twenty-four hours found 27 survivals (33 per cent.). Probably these late cases were more carefully selected and the numbers are small, but on grounds of percentage mortality there is in this series little to choose between the two classes.

When, however, they are examined in detail, to see how far the successful cases are profitable, there is a marked difference. Of the late cases only 7 of the survivors had wounds of the alimentary canal, namely, 3 of the colon, 4 of the small intestine. Two of the latter are included in the only 4 cases of the whole series who are known to have died after arrival at the base. So that out of 19 "successful" cases operated on after twenty-four hours, only 5 (26 per cent.) were permanent cures of men wounded in the stomach or intestines. The rest of the survivors were men whose chief essential injury was haemorrhage from solid organs, mesentery, or omentum.

In the early cases the proportion is quite different; 80 cases were operated on within twelve hours, and 33 recovered. Of these, 26 (80 per cent.) were wounded in the stomach or intestines.

Apparently what happens is that most men wounded in the abdomen, with the exception of those already referred to in whom the injury is obviously limited to the liver and kidneys, have some injury to the alimentary canal. As time goes on some of these die, and others develop peritonitis which proves fatal whether they are operated on or not. The survivors, with or without operation, are almost all those whose chief injury is haemorrhage. Their bleeding has by this time ceased, and is not necessarily fatal if left alone. In these late cases, then, there is a much greater chance of performing an unnecessary and unprofitable operation. This is not shown in statistics, where unnecessary operations, unless they kill the patient, are shown as successes.

The question is what extent of delay renders operation as a rule unprofitable. A German surgeon in an advanced operating centre was led by his experience² to fix a limit of twelve hours. This is certainly too low. Out of the 15 recoveries in this series amongst those operated on between twelve and twenty-four hours, 10 (66 per cent.) were wounds of the alimentary canal.

A distinction has already been drawn between operations which are "successful" in the sense that the patient survives them, and those which are "profitable" in the sense that they cure an otherwise fatal injury. If we assume that wounds which open the stomach or intestine are necessarily fatal if untreated, and that haemorrhage is not, the proportion of profitable operations in this series to those which were merely successful is—

In the first twelve hours	4 to 1
In the second twelve hours	2 to 1
Later	1 to 3

It is impossible to lay down any rule (this series includes a successful resection after thirty-six hours), but roughly it seems that operation is very profitable in the first twelve hours—and well worth while in the second twelve hours.

After this time the chances are in favour of its being unnecessary, even if the patient survives it—so that preference should always be given to early cases, even if their condition is less good.

General Condition: Pulse.

As regards the pulse the cases may be divided into those with a rate under 120, and those with a rate of 120 or over. The pulse was counted on the table before the anaesthetic was given and after measures had been taken to improve the patient's condition by rest and warmth. The quality of the pulse is almost equally important, but cannot be so accurately expressed. Here the distinction in mortality is sharply marked. Of the 131 cases in which the pulse was counted, in 77 it was under 120, and of these, 42 (54 per cent.) recovered. Of the 54 in whom it was 120 or over, only 14 (25 per cent.) recovered.

As far as these cases are concerned, therefore, the chance of survival of men with a pulse under 120 is more than double that of men with a more rapid pulse, and this in spite of the fact that some of the most seriously injured cases had originally a slow pulse, which rose suddenly in the course of the operation.

To make a rule never to operate on cases with a pulse over 120 would, however, in this series, have resulted in the loss of about a dozen lives. The most unpromising cases can occasionally be saved—for example:

Cpl. P., a delicate-looking youth, in civil life a chartered accountant, took part in a raid on June 27th, 1916. He was returning in charge of six prisoners when the enemy opened fire with a machine-gun. He and his prisoners tumbled hastily into our trench, and he fell on to a bayonet which entered his abdomen and chest.

Seven hours later he arrived in hospital collapsed and pulseless. After rest, warmth, and infusion, the pulse became "just perceptible." He was pale and cold, with a rigid abdomen and occasional haematemesis. There seemed no prospect of improvement, so his abdomen was opened, a quantity of blood cleared out, and two wounds of the stomach repaired. In the course of the night he vomited violently and burst open his wound. This was sewn up again, and the third day he was rather better, with a pulse of 120. His haemothorax then became septic, and was drained. He recovered, and was sent to the base on July 29th. The medical officer in charge notes that his general condition was then "excellent."

The objection to risking a death on the table is largely sentimental. If the patient is as fit as he is ever likely to be, and has a reasonable chance of surviving the operation, this danger may be faced like any other. The operation may be unsuccessful, but it is not likely to be unnecessary. But if conditions do not allow of all cases being treated promptly it is clearly better to take those with a low pulse rate first, and to try and improve the condition of the others meanwhile.

Cases of Apparently Slight Wounds.

If care is taken to exclude those who have been wounded too long, and those whose condition is too bad, there still remains the danger of failing to include those who have scarcely any symptoms. Minute wounds of the abdominal wall, without pain, rigidity, or vomiting, are sometimes associated with serious internal injuries—for example:

Case 1.—Pte. W., admitted February 1st, 1917, with tangential bullet wound of lower abdominal wall received four hours before admission. Condition excellent; pulse 90; no vomiting; abdomen soft, movable, and painless; no tenderness except over the actual track. Wound explored; a slit half an inch long found in the peritoneum. Laparotomy: Three perforations of the small intestines. Repair; recovery.

Case 2.—Cpl. C., admitted January 14th, 1917, with small bomb wound near the umbilicus received two and a half hours earlier. Condition very good; pulse 90; no rigidity or vomiting. The wound was explored and found to penetrate. Laparotomy: One wound in the small intestine, plugged by the missile. Repair; recovery.

Case 3.—Spr. D., small central wound of abdomen received twenty-six hours before admission. Condition very good; pulse 100; vomited once on being hit, never since. Abdomen soft and free from tenderness. The only positive symptom a slight "diarrhoea pain." Some free blood, a wound of the jejunum, which was empty. Repair; recovery.

Case 4.—Second Lieutenant C., admitted December 21st, 1916, with minute grenade wound in right iliac fossa received nineteen hours earlier. This appeared, and was considered, a superficial graze, and the patient came in as "G.S.W. eyes." Pulse 100; no rigidity; had vomited once only. There was

slight local pain under the wound. Explored: Much free blood; one wound of caecum, three of small intestine. Repair; recovery.

As is seen in these four cases, the results of operation before symptoms occur are very good. Their absence is probably due to the wounded gut being empty at the time, and if it can be repaired before it fills and leaks no infection of the peritoneum need arise.

The only way to avoid missing these very profitable cases is to explore every wound of the abdominal wall, front or back, whether symptoms are present or not. If the missile is in the wall, the patient is quit of it at the cost of a two-inch incision. If the track is found to penetrate, or is lost in the direction of the peritoneum, or if the skin is peppered with a number of minute wounds, the best course is to open the abdomen rather than to miss the best opportunity by waiting for signs of peritonitis to develop.

Organization of Operations.

The only other difficulty which arises in selection is to balance the claims of abdominal cases against those of other wounded in busy times. Keen surgeons are apt to concentrate on these technically interesting cases to the prejudice of other men whose lives are equally valuable, and who have more chance of being rendered fit for further service.

This tendency can be controlled by having an experienced and sensible surgeon in charge of the pre-operation ward, whose duty it is to decide the order in which cases go to the theatre, and, if necessary, the surgeons to whom they are allotted.

The real remedy, however, is to be found in eliminating waste of time, which is the chief reason why any cases, abdominal or other, fail to receive prompt treatment. Most time is wasted, not in actual operating, but in getting patients in and out of the theatre, anaesthetizing and cleaning them. If there is a sufficient supply of stretcher-bearers under a competent N.C.O., and if two tables are available for each surgeon, so that a second patient can be anaesthetized and cleaned on the other table by the time the first operation is finished, this kind of delay can be entirely got rid of. The operator has only to change his gloves and go straight on.

The other avoidable cause of delay is slowness in operating. Provided an operation is gentle and thorough, the quicker it is done the better. Men wounded in the abdomen are nearly all suffering from shock, what pulse they have is liable to fade away under prolonged exposure of their viscera, and ten minutes more or less may turn the scale between death and recovery. So that in the interests of the individual patient, as well as of others, speed is essential. Rapid work depends more on character than on manual dexterity. Method, decision, and silence are essential to it, and a clock in the theatre is the only known antidote to self-deception.

A competent surgeon, with a good sister helping him, can open the abdomen, search the small and large intestines, and close it, in twenty minutes. Ordinary repairs will extend this time to half an hour. But operators who habitually take an hour or more over a simple case should not be allowed to attempt this branch of surgery.

CONCLUSIONS.

1. The decision as to whether a man wounded in the abdomen should be operated on or not is usually based on the time which has elapsed since the injury and the rate and character of the pulse.

2. Of the patients who survive operation performed in the first twelve hours a high proportion will have had their lives saved by it, and this is true in a lesser degree of those operated on in the second twelve hours. After this time most of those who survive operation are those whose injuries were not originally fatal.

3. Men with a pulse of 120 or over have less than half the chance of survival of men with a lower pulse.

4. Recently wounded men, with a rapid pulse, should nevertheless be operated on, provided that their condition is as good as it is ever likely to be, that they have a reasonable prospect of surviving the actual operation, and that the time taken does not prevent the proper treatment of other wounded.

5. Every wound of the abdominal wall, however slight, should be explored, whether signs of internal injury are present or not. If it is found to be penetrating, the abdomen should be opened.

6. The necessity for deciding between the claims of abdominal and other cases can be best avoided by good theatre organization, the provision of two tables for each surgeon, and by not allowing slow operators to do abdominal work. If these measures are insufficient the decision should be left in the hands of the surgeon in charge of the pre-operation ward.

ABDOMINAL OPERATIONS AT AN ADVANCED OPERATING CENTRE.

FIFTY CONSECUTIVE CASES OF PENETRATING WOUNDS OF ABDOMEN, IN SIXTEEN OF WHICH THE CHEST WAS ALSO INVOLVED.

BY

CHARLES F. M. SAINT, M.D., M.S., F.R.C.S. ENG.,
CAPTAIN R.A.M.C.(T.).

The Operating Centre.

THE centre was situated in a village in advance of the corresponding group of casualty clearing stations. The roads between them at the time presented a very rough surface, and were heavily charged with transport, so that at least one hour's very bad journey was saved.

The accommodation comprised part of a building, without any special heating or lighting arrangements, and marquees. The heating was done by oil stoves, the lighting by an acetylene plant. In the building were the operating theatre, sterilizing room, and a post-operative room of twelve beds, while outside were the reception marquee and thirty-eight extra beds, partially distributed in a long ward of four contiguous marquees and in two separate.

The operating theatre was large enough for two tables, had a tiled floor, and large windows looking both east and south. The walls were distempered white. The sterilizing room adjoined the theatre, and was fitted with a large metal-lined washing-up trough. The post-operative ward of twelve beds was a large, light, airy room, with distempered walls and a parquet floor. The marquees were conveniently arranged adjacent to the building. The reception marquee was fitted with four pairs of trestles for stretchers, and served also as pre-operation and resuscitation departments. The big ward of four marquees joined together had accommodation for twenty-six patients, and two other single marquees were each fitted with six beds, one for officers and one for badly infected cases.

The Staff.

With the exception of the first few days, when a second team was attached (Captain Stevenson, R.A.M.C.), the operative work was done by one surgical team, consisting of surgeon, anaesthetist, sister, and theatre orderly, while the general administration was carried on most of the time by a section of the field ambulance to which the centre was attached. Four extra sisters were attached to superintend the nursing in the wards, the staff of orderlies being supplied by the field ambulance. At a later period, with an increase in the military activities, three extra surgical teams were attached to the centre, and the beds increased to 75. A special marquee was set apart for resuscitation, and a second for those cases considered as hopeless on admission, the reception marquee being utilized only for the reception of cases and the preparation of those to be operated on at once.

PRE-OPERATIVE TREATMENT.

Special efforts were made to evacuate the abdominal cases as quickly as possible from the line, and all concerned displayed the greatest keenness in achieving this. How far it succeeded will be seen in the study of the time intervals between wounding and arrival at the centre.

The reception marquee was always kept very warm, and on arrival the patient was taken to it, examined, and judged fit or unfit for operation.

If considered fit for operation he was washed and put in pyjamas, and morphine and atropine administered hypodermically if necessary. It was not uncommon for the patient to arrive already deeply under morphine; this was found to be especially dangerous in those cases with chest wounds, as great difficulty was sometimes experienced with the respiration after the operation. Rinsing of the mouth with water was allowed, but no drinks. The urine was always examined before operating, but if the patient failed to pass it himself catheterization was deferred till he came into the operating theatre. The operation was commenced one hour after his arrival. At the suggestion of Captain Stevenson a special stretcher was used for these cases to avoid any excessive amount of lifting about. A coarse palliasse was stitched down the sides so as to leave two tunnels through which the stretcher poles could pass, and two iron bars with rings at the ends were slipped over the pole handles to keep them apart. Over this was placed a ground sheet and then an ordinary sheet. The advantage of this was that the patient remained on the palliasse until he arrived in the ward, the poles being slipped out when he was placed on the operating table.

If the patient was considered unfit for operation the usual resuscitation procedures were carried out. He was made as comfortable as possible, morphine was administered if necessary and heating up was done by a Beatrice stove in a kerosene tin with a chimney leading under a cradle over the stretcher. Stimulants were given hypodermically as required, and saline, preferably by the intravenous method. In a few cases blood transfusion was performed, but only one of these was an intraperitoneal lesion. The method used was vein to vein by means of an improvised tube—an ordinary 6 in. glass testing pipette with $\frac{1}{8}$ in. lumen; it was bent into a U-shape, the limbs of the U being 1 in. long. A small flange was made at the ends to prevent the tube slipping out of the veins. The tube was sterilized and washed through with liquid paraffin before use (soft paraffin is undoubtedly better). The median basilic veins were used, an injection of $\frac{1}{2}$ per cent. novocain being given to produce anaesthesia. In one case where the blood refused to flow into the vein of the recipient, a second incision was made in the neck and transfusion made into the external jugular vein, which was seen to empty with each inspiration. The veins were connected for twenty minutes. The tube can easily be modified for an artery to vein transfusion, and may be made of metal. The method is not so good as Crile's No. 17 transfusion tube, but in an emergency is easily carried out, especially if none of the usual means is at hand. In the abdominal case so treated the pulse-rate came down from 142 to 108 in twenty minutes and remained so for about half an hour, when the patient quite suddenly collapsed again and died in another hour. The time for operation was settled by the progress of the case.

If the interval between wounding and admission was more than eighteen to twenty-four hours expectant treatment was adopted. The patient was put on a Fowler frame, the wound dressed, and fomentations applied to the abdomen, if necessary. Morphine was given, and fluid by the mouth gradually commenced.

When the case was judged hopeless the patient was made as comfortable as possible, morphine was not withheld, and fluids were allowed by the mouth.

A chamber for heating the pyjamas was made of a box the bottom of which was knocked out and replaced by wire netting. It was placed on a stand with a Beatrice stove underneath. By this means a stock of warm clothing was always ready for use.

OPERATIVE TREATMENT.

The patient was taken to the operating room, which was kept at a temperature of 65° to 70° Fahr. The anaesthetic administered was chiefly ether, reinforced at times by chloroform, and given by the Shipway apparatus. In the worst cases continuous oxygen was given simultaneously by attaching a cylinder. If the patient had been unable to micturate, a catheter was now passed and the urine examined.

The skin was prepared under the anaesthetic; it was shaved with spirit soap for preference, followed by the

application of turpentine, if it could be obtained, then more spirit soap and methylated spirit, and finally 5 per cent. picric acid solution in spirit.

Dry sterile towels were placed next to the patient, and covered by hot towels wrung out of 1 in 40 carbolic. Sterilized mops were used wet out of 1 in 10,000 biniodide lotion, and abdominal swabs out of hot saline. Instruments were boiled and kept in 1 in 40 carbolic acid, knives, etc., in spirit, after cresol. Masks were worn by surgeon and assistant, and gowns with long sleeves for preference. The lotion for the hands was 1 in 10,000 biniodide.

The principles observed in operating were: (1) Good exposure; (2) minimum retraction; (3) gentle manipulation; (4) speed, consistent with care and thoroughness.

The operation was begun by excising the wound; subsequently the incision was planned to obtain the best exposure of the affected area, as indicated by the position of the wound and the direction of the track. Hence in some cases it commenced at the excised wound, whilst in others it was entirely a separate opening. When separate a mid-line or transverse or oblique lateral incision was preferably employed, with a view to causing as little damage as possible to the belly wall. When the incision was completed wound gauzes were put on. The extent of the exploration was determined in great measure by the direction of the track, especially with regard to the solid viscera and to the more or less fixed hollow viscera.

When the small gut area was involved, the first loop that presented was taken, and, commencing at this point, examination of the entire length of it was carried out by passing up and down. The exploration was completed as quickly and gently as possible, any exposed viscera being covered with swabs out of hot saline, bleeding was controlled at once, clamps were fixed over the holes in the hollow viscera to stop leakage and serve as guides, and other injuries were noted. Treatment was as conservative as possible, no resection being done unless the affected viscera appeared damaged beyond repair, or the risk of haemorrhage seemed too great, that is, in the solid viscera.

In the case of the hollow viscera silk was used as suture material, and a transverse line of sutures was preferred to a purse-string in holes in the gut. While a single layer only was commonly used for the small gut, in the stomach and colon an additional layer of Lembert sutures was introduced, frequently reinforced by tags of omentum or appendices epiploicae. After resection of gut end-to-end anastomosis was employed, the suture line being strengthened by a few Lembert sutures. Paul's tubes were only used if the patient was so ill that it would have been fatal to prolong the operation; both patients in whom they were employed died within a few hours of operation. Intraperitoneal bladder wounds were closed with or without drainage of the extraperitoneal track, and no suprapubic cystostomy was done. In injuries of the solid viscera, it was routine to bipp all tracks in them, with the object of controlling sepsis, and, if bleeding resulted, it was controlled by deep catgut sutures. Catgut was always used for suturing, but silk was employed for ligaturing spleen and kidney pedicles.

The cleaning of the peritoneum varied with the class of case. When solid viscera alone were injured blood clot was removed and excessive fluid mopped up, and only in a very large extravasation was a saline irrigation used. In injuries of the hollow viscera, if the extravasation of contents were quite small and limited, all that was done was local cleansing and mopping out with flavine solution 1 in 1,000. If, on the other hand, the extravasation was widely diffused, as occurred chiefly in injury to the full stomach, the upper jejunum, the colon and bladder, the peritoneum was irrigated with flavine 1 in 10,000 or saline, at a temperature of 106° F., and a pelvic drain left in for forty-eight hours, either projecting from the lower end of the incision or from a separate suprapubic stab. There was no hesitation in leaving a smearing of bipp in any area which appeared rather soiled, and similarly all extraperitoneal tracks were bipped. If the foreign body was not encountered in the course of the general operation no prolonged search was made for it.

As a routine the incision was bipped and sutured in layers, the deeper layers with catgut, the skin with silk-

worm, including the superficial aponeurosis or muscle fibres. If the patient was very ill through-and-through sutures of thick silk only were employed.

When both the chest and abdomen were involved the essential feature of the operation was that the abdomen was dealt with through the diaphragm from above, and that the diaphragm itself was repaired from the thoracic aspect. The wound was excised and the injured rib removed for four or five inches. The incision was then carried on, if necessary, along the rib or intercostal space to the abdomen, reaching the edge of the rectus; in other words, it took the direction of the intercostal nerves. The wound in the diaphragm was enlarged if required, the excision extending in some cases right to its costal attachment. By this proceeding the splenic and liver regions were freely exposed by a minimum amount of retraction or none at all, and operations which by the abdominal route had often given rise to much difficulty became relatively easy as the injured viscera presented in the aperture. Indeed, in two cases the spleen was found prolapsed through the wound in the diaphragm, and in one of them a considerable portion of the fundus of the stomach was also present as well as the splenic flexure of the colon. The abdominal lesion having been dealt with, the aperture in the diaphragm was bipped and sutured with strong catgut and the abdomen closed. The chest condition was then investigated. Extravasated blood was removed, any lung track bipped and sutured, and the pleural cavity irrigated with 1 in 10,000 flavine and mopped dry. Finally the parietal incision was bipped and sutured up completely in layers, no drainage of the chest being employed. The anaesthetic for these cases was chloroform and oxygen given by the Shipway method. No detrimental effects were noticed as a result of this method of procedure.

Before leaving the theatre, if the patients were much shocked, an intravenous infusion of 1 to 1½ pints of saline was given. The injection which proved most satisfactory was composed of 3 per cent. gum acacia, 1 per cent. glucose, and 0.9 per cent. sodium chloride. With the injection, a hypodermic of camphor gr. ij in ether 3 ss was usually given.

POST-OPERATIVE TREATMENT.

On coming round from the anaesthetic the patients were propped up either with pillows or on a Fowler's bed, and everything possible was done to stimulate them. If the stomach was injured, a pint of saline with 1 oz. of brandy was given every four hours by the rectum and liquids by the mouth after twenty-four hours, sips at first, gradually increasing the amount. In injury to the small gut, especially if low down, small quantities of liquid were given by the mouth from the beginning and rectal saline with brandy as above described. In injuries of the colon as much fluid and stimulant as possible was given by the mouth. When an extraperitoneal injury of the bladder and rectum was present in addition to intra-abdominal lesions, the bowels were confined, if possible, for seven days with pil. opii gr. j, given two or three times daily as required.

When the chest was involved, respiratory difficulty was combated by position and the administration of oxygen, and hypodermic injections of camphor gr. j in ether m xv were freely given, in some cases every half-hour for a few hours. Morphine was given at first if much pain was complained of, but subsequently omnopon was preferred as a soporific.

In all cases the patients were kept at the advanced operating centre until they were quite fit, the average being about a fortnight, and when they were evacuated they were usually on full diet.

Of the 50 cases, 33, or 66 per cent., recovered, and 17, or 34 per cent., died.

The average time of all cases before operation was 8½ hours. Excluding Case No. 11, which was 42 hours, the average was 7.6 hours. Case No. 11 was operated on because of abscess and cellulitis in the right groin and iliac fossa; there was a fracture of the ilium, extraperitoneal and intraperitoneal holes in the caecum, and several large holes in the small gut, with widely diffused extravasation and advanced peritonitis. The average time among the recoveries was 7.3 hours, and that among the deaths, omitting Case No. 11, was 8.3 hours.

TABLE I.—Thirty-three Recoveries.

No. of Case.	Time in Hours.	Small Gut.	Large Gut.	Liver.	Spleen.	Kidney.	Omentum and Mesentery.	Chest.	Other Complications.
1	12	1	—	—	—	—	—	—	—
3	4	—	—	1	—	1	—	1	Fractured transverse processes of vertebrae. Flesh wound of thigh.

50	5	—	—	1	—	1	—	—	Fractured rib and transverse process of vertebra.

H., Haematoma. R., Hernia. D., Hernia through diaphragm.

All the cases were shell wounds except No. 20 (gun recoil) and No. 30 (bomb). The stomach was wounded in one case only, No. 36 (part of wall); the pancreas also was wounded in one case only, No. 31. The spleen was excised in Cases 31 and 32, and the kidney in Cases 25 and 50. The bladder was involved in Cases 7 and 30. Resection was performed in Cases 7 and 41.

In the 50 operations—

The stomach was injured in	5 cases
The small gut in...	22 "
The large gut in...	14 "
The liver in	12 "
The spleen in	10 "
The kidney in	6 "
The pancreas in	1 case
The omentum and mesentery in...	21 cases
The bladder in	4 "
The chest was perforated in	16 "
Associated fractures, apart from the fractured ribs in thoraco-abdominal wounds, in	18 "
Resection was performed in	6 "
Anastomosis was performed without resection, one of the jejunum and one of both small and large gut, in...	2 "

TABLE II.—Seventeen Deaths.

No. of Case.	Time in Hours.	Stomach.	Small Gut.	Large Gut.	Liver.	Spleen.	Omentum and Mesentery.	Chest.	Other Complications.
2	9	—	—	1	—	—	—	—	Multiple wounds; toes and fingers amputated.
6	8	—	1	1	—	—	—	—	—
8	12	—	1	1	—	—	—	—	Both small gut and colon divided; double anastomosis; fractured ilio-sacral region.
10	17	—	1	1	—	—	1	—	Multiple; knee-joint with fracture and fractured ulna.
11	42	—	1	1	—	—	1	—	Fractured ilium.
13	—	—	1	—	—	—	—	—	(Two large protrusions of gut.)
15	9	—	1	1	—	—	—	—	—
21	6	—	1	1	—	—	1	—	(Very large protrusion of gut.)
23	2½	1	—	—	1	—	1	—	—
26	2½	—	—	1	1	—	—	—	Fractured ilium.
28	7	—	1	1	—	—	—	—	—
39	10	—	—	—	1	—	—	—	Fractured transverse process of vertebra.
40	11½	1	—	—	—	1	1	1	Compound fracture of skull; penetrating.
42	8	—	1	—	—	—	1	—	Multiple; fractured clavicle, etc.
45	9	—	—	—	—	1	—	1	Multiple wounds; both knees, head, arm, etc.
46	—	—	1	1	—	—	1	—	Fractured body of vertebra.
47	8	1	—	—	1	1	—	1	—

All the wounds were caused by shells with the exception of Cases 23 and 26 (bomb wounds).

The kidney was involved in two cases (Nos. 15 and 39); the bladder also was injured in two cases only (Nos. 5 and 26). Resection was performed in four cases (Nos. 5, 28, 42, and 46). Case 45 had two wounds of lung and one of heart. The spleen was excised in Case 47.

In the 17 deaths there were—

2 cases in which the intra-abdominal injury was limited to solid viscera:

Case 39.—Injury to liver and kidney and fractured transverse process of vertebra. *Post mortem* there was no sepsis, and the liver presented the typical appearances of delayed chloroform poisoning.

Case 45.—In this case there were, in addition to a ruptured spleen, two perforating wounds of the lung, a wound of the left ventricle of the heart, and multiple peripheral wounds, including both knee-joints.

3 cases in which the stomach was perforated (Cases 23, 40, and 47).

2 cases in which the small gut alone was injured (Cases 13 and 42).

2 cases in which the large gut alone was injured (Cases 2 and 26).

8 cases in which both large and small gut were injured (Cases 5, 8, 10, 11, 15, 21, 23, and 46).

8 cases had fractures associated with the intra-abdominal lesions apart from the fractured ribs of the patients with thoraco-abdominal wounds. These included three fractures of the pelvis and one penetrating head wound.

Almost all the deaths occurred within twenty-four hours of the operation. There were—

3 splenectomies with one death (Case 47).

2 nephrectomies with no death.

6 resections with four deaths (Cases, 5, 28, 42, and 46).

2 anastomoses without resection; one of the jejunum (Case 20) recovered, and the second, a double anastomosis of small and large gut (Case 8), died.

16 cases with associated perforation of the chest, with three deaths (Cases 40, 45, and 47).

No untoward results were observed in those cases in which the foreign body was not removed at the operation. No case underwent a second operation, and no chest required reopening. In no case did the wound break down, although there were one or two stitch abscesses, which occurred in the region of the original wound. The sutures were not removed before the seventeenth day.

AN ABDUCTION SPLINT FOR THE FEMUR.

BY
CAPTAIN DENNIS W. CRILE,
HARVARD SURGICAL UNIT, R.A.M.C.

THE war has demonstrated that for the early treatment and transportation of patients with fractures of the femur Thomas's knee-splint is the best general utility splint, and that rigid extension from the ischial tuberosity is practical. There is, however, a class of fractures of the femur—that is,

FIG. 1.

those in the upper third—which presents great difficulty to treatment with Thomas's splint, particularly when accompanied by extensive flesh wounds of the buttocks and hips. These cases require abduction as well as extension. Their wounds should be available for dressing. They and their splint should be easily transported, and immobilization of the fracture maintained.

There is no splint in use at present which performs all of these functions. Thomas's splint does not produce abduction, and the ring interferes with the dressing of high thigh and buttock wounds. Bradford's frame, the Hodgen-Balkan combination, and Sinclair's bed cannot be transported. The Jones abduction frame is cumbersome, expensive, and often very uncomfortable. All of these tie the patient and hold him so that he is unable to move. Sinclair's bed tilts him up the wrong way—head downwards—so that pus tends to track upwards. All of these appliances produce abduction at the hip-joint by swinging the leg away from the mid-line of the body; thus the leg protrudes from the side of a stretcher or bed and is bumped against in transport. There is another way of producing abduction, that is, by tilting the pelvis. The diagrams (Fig. 1) will explain this. By making use of this principle and bearing in mind that most high compound fractures of the femur are accompanied by extensive flesh wounds of the buttocks, thighs, or hips, I have devised a splint,

FIG. 2.

based upon the lines of the Thomas, which has proved useful in my hands.

The Thomas ring is transposed to the uninjured thigh, producing a base for extension against the ischial tuberosity on the sound side of the pelvis (Fig. 2). Coming from this ring is the inner rod of the splint, which has an offset near its origin for the genitals. This rod is continued as in the

ordinary Thomas into the outer rod which fastens to an iliac pad, since the ring is on the opposite thigh. This pad fits just below and parallel to the crest of the ilium on the same side as the fractured femur. The pad is continued into a broad band which passes round behind the pelvis and fits snugly to the hollow of the sacrum. When the pelvis is tilted by counter force on the opposite tuber ischium, this pad impinges, not on the iliac crest, but just below it on the plane of the ilium, which is well protected by the gluteus medius muscle. In front the ilio pad and the ring are connected by an iron rod running transversely across the body (Fig. 3). This is adjustable for width, so that the splint will fit any sized man. The band which passes around the back buckles to this transverse bar in front. The outer rod of the splint is also adjustable, and serves the double purpose of increasing the length of the splint and of varying the abduction angle. The material used is $\frac{3}{8}$ in. iron rod for all parts except the pelvic band, which is a strip of sheet iron 2 in. wide, curved on the flat to fit the back (Fig. 4). The ring is made in varying sizes, from 20 in. to 26 in. A 22 in. ring is the best for universal use. The adjustments are made by means of a coarse screw and nuts. The ring and the iliac pad are well padded. The pelvic band is lightly padded. These parts are covered with leather, and the pelvic band continued into a strap. The buckle is fixed to the transverse bar in front.

FIG. 3.

This splint is applicable to any case in which abduction is required. It produces a maximum true abduction angle of 45 degrees, and can be adjusted to any lesser angle. The absence of a ring round the wounded thigh leaves space for dressings. The hip-joint is fixed. The back, arms, and sound leg are free. This enables the patient to move about in bed, changing the pressure points, and thus preventing bedsores. He can sit up on a back rest. He can raise his buttocks off the bed by making a tripod of his shoulders and the heel of the sound leg, and thus use a bedpan in comfort. One patient has been able to roll over and sleep face downwards. The splint is light and inexpensive compared to other abduction appliances, and is as easily transported as the ordinary Thomas.

Fixed extension can be changed to weight and pulley extension when desired. I have been using a graduated spiral spring extension on the principle of the spring

FIG. 4.

balance. This reads in pounds. I have seen the ischial tuberosity bear a push of 20 lb. for months without making the skin sore.

Flexion at the hip can be obtained by bending the splint or by elevating the feet as with a Thomas. I have seen no tendency for scoliosis to persist after the splint is removed. Within a day or two the lumbar vertebrae resume their normal position.

Two of the cases which I have treated with this splint follow. The x-ray plates are shown as black and white drawings, since the plates were too thin to make good prints.

CASE I.

Driver S. Bullet wound, September 30th, 1917. Entrance wound in left groin; exit left great trochanter. Operation same day: Wounds excised and cleaned; bipp. Comminuted fracture of femur—upper fragment in abduction. Abduction splint applied. October 20th: Comfortable; no fever; wounds clean. Body covered with boils due to pediculi. Boil over sacrum ruptured. October 25th: Boil over sacrum healed; no bed sore.

November 16th: X ray showed spiral fracture through lesser trochanter with a split running into great trochanter and moderate comminution. Upper and lower fragments in good alignment. Abduction at hip of 35 degrees. Some callus near lesser trochanter.

November 17th: Wounds healed. Bony union—all movements at hip and knee good. December 15th: Up and walking in calliper splint. Both legs are the same length.

CASE II.

Pte. J. Bullet wound, October 22nd, 1917. Fracture of left femur at lesser trochanter. Operation: Foreign body removed; wound cleaned; Thomas splint.

November 10th: X ray showed spiral fracture beginning just above the lesser trochanter and following the spiral line,

FIG. 5.—Tracings of x-ray plates of Pte. J. A, Fracture while on Thomas splint. Upper fragment in abduction. Angulation at fracture and consequent shortening. B, Fracture while on abduction splint. Fragments in line with slight over-correction and 1 cm. over-extension.

leaving the lesser trochanter intact on the upper fragment. Considerable comminution and loss of some cortex. Upper fragment is turned out in abduction and is flexed at the hip. Lower fragment in poor line. There is marked angulation at the point of fracture. Plate shows some hazy callus, probably not bony.

Operation, November 16th: Fragments forced into position; callus broken up. Nails driven into condyles for extension. Abduction splint applied. On November 18th x ray showed marked improvement. There was slight over-correction (Fig. 5). Abduction angle lessened from 45 to 35 degrees. Alignment perfect.

December 12th: Condylar nails loose; removed. Adhesive leg extension. December 25th: Union firm.

Measurements:

	Left.	Right.
Great trochanter to adductor tubercle	41 cm.	40 cm.
Anterior iliac spine to adductor tubercle	45 cm.	44 cm.
Anterior iliac spine to internal malleolus	85.5 cm.	85 cm.

The fractured femur is 1 cm. longer than the sound one.

A METHOD OF CITRATED BLOOD TRANSFUSION.

BY
OSWALD H. ROBERTSON, CAPT. M.O.R.C., U.S.A.,
U.S. ARMY BASE HOSPITAL No. 5.

TRANSFUSION with citrated blood has had a fairly wide use in civil practice during the past few years. Reports have varied concerning the satisfaction this method has given. Some workers report excellent results. Others have experienced certain drawbacks, especially the occurrence of reactions after transfusion. Although the method of citrate transfusion is very simple, definite precautions must be observed or the blood will undergo changes, while outside the body, that may render it toxic. The very fact of the apparent simplicity of transfusion with citrated blood has undoubtedly led in many instances to a lack of appreciation of the care necessary in carrying out the technique, with consequent undesirable after-effects; blood is a very delicate tissue, and must be handled accordingly. The chief consideration is to get the blood quickly and cleanly into the citrate solution so that coagulation changes, which always begin the moment the blood leaves its containing vessel, may be stepped as soon as possible. The passage leading from the vein to the citrate must be of large diameter, as short as convenience will permit, and absolutely clean. The blood must be well mixed with the citrate at once. With unsuitable apparatus, clotting will probably occur in the tube system, which, although it may not entirely occlude the lumen, will slow the flow to such an extent that the blood undergoes considerable change before reaching the citrate. This is the kind of blood which tends to produce reactions when transfused. With properly constructed apparatus and careful technique, reactions ought to be of infrequent occurrence.

APPARATUS.

The apparatus shown in the diagram has been found satisfactory. It is simple in use and can easily be made out of material at hand.

Transfusion apparatus.

A. Transfusion Bottle.

A wide-mouthed well cleaned drug bottle with a capacity of 900 to 1,000 c.cm. will serve as the transfusion bottle. It should be short and wide, rather than long and narrow, since this shape diminishes the length of intake tube necessary. Three marks are made on the bottle with a file, one at the 660 c.cm., one at the 760 c.cm., and the other at the 860 c.cm. levels, indicating 500, 600, and 700 c.cm. of blood respectively. It is well to use a glass pencil as well to make the marks more distinct. 160 c.cm. of a 3.8 per cent. solution of sodium citrate (isotonic), made up with freshly distilled water and filtered, is placed in the bottle, which is stoppered with a cotton plug wrapped

470 MEDICAL JOURNAL OF THE SOUTH AFRICAN MEDICAL ASSOCIATION
in gauze. A second piece of gauze is tied on over the stopper and neck of the bottle. It is then autoclaved; half an hour at 105° C. should be the minimum. Where a number of transfusions are being given half a dozen or more of these bottles are prepared at once.

B. Bleeding System.

The needle (a) should be of a large bore—1.5 to 2 mm. internal diameter was found to work well—and not more than 3.5 cm. long (1.5 in.). It should have a fairly large olive-shaped base. The needle is the most important part of the apparatus, and requires careful attention. Before each bleeding it should be carefully sharpened. The most important consideration in the sharpening is to produce a good spear-point. If the point is well protected when not in use by a metal barrel or piece of rubber tubing, sharpening will require only a moment or so. The needle must be kept scrupulously clean, and after each bleeding should be washed out at once, all fragments of fibrin or clot removed from the base, and small pieces of cotton-wool soaked in liquid paraffin thrust through the lumen with the stilette. The whole needle is well oiled before being put away.

The rubber connexion (b) should be flexible, and not more than 8 cm. long (3 in.). The inner surface should be smooth, and the lumen slightly smaller than that of the glass inlet tube (c). If the rubber connexion fits snugly over the base of the needle, tying it on is not necessary.

The glass inlet tube (d) is made of a large-bore glass tubing about 6 mm. internal diameter. It should extend below the level (A) of the solution in the bottle.

C. Transfusing System.

The needle (e) employed has a bore about half the size of that used for bleeding. The length is not important. As shown in the illustration, the needle is attached to a short glass tube (g) by means of a small piece of rubber tubing (f).^{*} The free end of the glass tube is thrust into the end of the long rubber tube (h) after the needle is in the vein. The rubber tube (h) may be of any convenient length. The glass tube (i) is bent so that the end projects into the lowest part of the bottle. In this way almost every drop of blood in the bottle may be given.

D. Pump.

The bulb of an Ingram syringe serves as a pump with the valves arranged as in the diagram. Suction or pressure can be made by reversing the ends.

PROCEDURE OF BLEEDING.

The donor's arm is extended at a right angle to the body. The skin of the antecubital space is scrubbed up with soap and water, and the sterilization completed with alcohol. A tourniquet is applied to the arm high up, and a suitable vein chosen, remembering that the needle is to be inserted towards the hand. It is very important to have as large a vein as possible. Opening and closing the fist and flicking the skin below the point chosen for venepuncture aids much in dilating the veins. At the point selected to puncture a small amount of novocain is injected intracutaneously. The tourniquet is then released. The apparatus is assembled as shown in the diagram, great care being taken to keep all the open parts sterile. The stopcock (j) is closed and the open end of the rubber tube (h) protected with a piece of sterile gauze which is conveniently held on by a pair of Spencer Wells forceps. Sufficient pressure is made with the pump to fill the bleeding system with solution. When the air has been driven out of the needle, the stopcock (c) on the connecting tube is closed. The pump bulb is reversed so that suction can be made when needed. The apparatus is now ready for use.

The tourniquet is again tightened sufficiently to make the veins stand out well, but not enough to obliterate the pulse. The cuff of a blood pressure apparatus makes an excellent tourniquet with a pressure kept at 50–60 mm. of Hg. A small nick is then made through the skin with the point of a scalpel. The bottle is placed on a stand close to the patient's arm in such a position that there

will be no kinking of the rubber connexion when the needle is in the vein. Slight suction is next made in the bottle. The skin opening is mopped dry with a piece of sterile gauze and the needle inserted for a short distance beneath the skin before entering the vein. The stopcock (c) is then opened and the needle is pushed into the vein immediately. The blood follows the column of solution down the tube without leaving an air space. A moderate degree of suction is maintained, and the donor continues to open and close his hand slowly, care being taken that he does not move his arm. It is essential to keep the needle immobile. The operator should hold it throughout the bleeding, steadying his hand against the donor's arm. With the free hand the bottle is given a rotary motion every few seconds in order to ensure thorough mixing of the blood. In doing this care should be taken to avoid pulling on the needle. With these precautions 500 to 700 c.cm. of blood can be easily and quickly obtained.

If clotting occurs for any reason, such as the needle slipping out of the vein or air leakage, and the blood ceases to flow, the tourniquet should be released, the stopcock closed, the needle withdrawn from the vein, and another attempt made with a fresh apparatus (needle, rubber connexion, and glass tube), using the same receiving bottle. It is usually better to take the other arm.

When the blood has reached the desired amount the tourniquet is removed, the stopcock closed, and the needle withdrawn. The bottle is again agitated for a few seconds.

If the donor's veins are small and the needle method fails, the vein can be cut down upon and a cannula used. Inserting a cannula into a vein is more difficult and time-consuming than the needle method, and offers greater possibility for infection.

The bottle of blood is placed in a glass jar containing water of about body temperature, in which it is kept during transfusion. The pump is reversed and the blood is now ready for transfusion. It will be noted that a column of blood is left in the intake tube after the bleeding has been stopped. This is done in order to avoid drawing into the bottle any little clumps of fibrin which may have begun to form immediately after the cessation of blood flow through the tubes. Leaving this blood does no harm. The blood should be given as soon after the bleeding as possible. If it is left standing for some time, changes may occur which make the blood less beneficial or even toxic.

PROCEDURE OF TRANSFUSION.

The recipient's arm is prepared in a manner similar to that described for the donor and a small amount of novocain injected into the site chosen for the vein puncture. It is well to tie the rubber stopper down to the bottle with two strips of adhesive plaster in order to prevent it from flying out when the pressure increases. After these preparations have been completed, sufficient pressure is put on the pump to fill the transfusing system with blood. The stopcock (i) is opened to let the air out, then closed. The tourniquet is next tightened. As soon as the needle enters the vein blood flows out through the short glass tube; the tourniquet is immediately released, the apparatus is connected up, the stopcock opened, and the pump started.[†] This technique is simple, and, if carried out carefully, there is no danger of forcing air into the vein. If the veins are collapsed or constricted, as is the case in certain patients with shock and haemorrhage, it may be necessary to cut down on the vein and use a glass or silver cannula instead of the needle.

By using a needle it is scarcely possible to force the blood in too rapidly. With a cannula care must be taken to go slowly. Ten minutes should be the minimum time for the introduction of 500 c.cm. of blood. Care should also be taken to close the stopcock before the air bubbles begin to pass up the tube.

REMARKS.

The question may be raised whether it is not better to coat the inside of the bottle and tubes with paraffin. Theoretically this would be a good thing, and in "peace" times it can be carried out. In rush periods, however, it

^{*} A needle with a close-fitting metal connexion is more easily handled. The metal connexion is slipped into the open end of the rubber tube (h) beforehand.

[†] The operator should hold the rubber-glass connexion firmly throughout the transfusion.

is quite impractical on account of the time required for the coating. Furthermore, judging by the excellent results obtained without the use of paraffin it seems questionable whether a paraffin coating is necessary.

An isotonic solution of sodium citrate is used instead of the 10 per cent. solution customarily employed, since it is felt that this maintains more nearly normal conditions for the blood. The amount of sodium citrate contained in the 160 c.cm. of "isocitrate" is approximately 6 grams. No harmful effects have ever been observed from the injection of this quantity of citrate, which is very much less than the supposedly toxic dose; 0.5 per cent. citrate has been shown to be sufficient to prevent clotting when well mixed with blood. When 500 c.cm. blood are drawn into 160 c.cm. of a 3.8 per cent. solution the resulting mixture is 0.9 per cent. citrate. With 700 c.cm. blood it is 0.7 per cent. An amount of blood as large as 800 c.cm. may be taken into this amount of citrate with safety if the blood flow is well maintained and the blood and citrate are thoroughly mixed. The sodium citrate in this mixture equals 0.6 per cent. In bleeding quantities over 700 c.cm. the flow through the needle frequently begins to slow up and mixing the blood and citrate becomes more difficult.

RESULTS.

This method was used under rush conditions. Forty-four transfusions were given to 38 patients. The patients transfused were cases of haemorrhage and shock—chiefly the former. Donors were always tested beforehand for compatibility of blood. The amount of blood given in a single transfusion varied from 400 c.cm. to 700 c.cm. The average quantity was between 500 c.cm. and 600 c.cm. In cases of very marked anaemia a second transfusion was occasionally given. Briefly it may be stated that the immediate effect of citrated blood was the same as that seen after the transfusion of blood by the other methods in common use. The blood pressure increased from 20 to 40 points afterwards. On one occasion there was a rise of 50 points, after only 450 c.cm. of blood. The general improvement was maintained and increased. The patients stood operation well, and subsequent progress was fully as satisfactory as seen ordinarily following transfusion. Of the 38 cases transfused 25 were evacuated to the base in good condition, and 13 died—a mortality of 34 per cent.

No reactions of any consequence were observed. In several instances there was slight chilliness during or immediately following transfusion, which soon passed off without further discomfort. It was impossible, under the rush conditions, to keep temperature charts on the majority of the patients, but in a number of instances in which temperatures were taken no rise occurred afterwards.

ADVANTAGES.

Aside from the chief advantage of its being a "one man job," this method has several other considerations in its favour. The apparatus can be made from materials easily obtained. The technique of transfusion is simple and quickly carried out. The bleeding can be done in a conveniently arranged room outside the resuscitation ward. The blood is then carried into the ward and given at the bedside without the necessity of moving the recipient, thus avoiding injury, which is often done to the patient in shock by moving him to the operating theatre, or even on to a table near by.

SUMMARY.

The use of citrated blood for transfusion seems to fill a definite need in that the technique is relatively simple, easily acquired, and can be carried out entirely by one medical officer. Furthermore, this method obviates the necessity of having the donor and recipient together, and the blood can be given at the bedside. Stress is laid on the fact that, although the technique is apparently very simple, certain definite precautions must be observed in the handling of the blood in order to obtain good results. The chief considerations in the technique are to get the blood quickly and cleanly into the citrate, to obtain prompt and thorough mixing of the blood with the citrate, and to transfuse the blood as soon as possible after the bleeding.

An apparatus is described which can easily be constructed, and has been found to work satisfactorily. The

blood is received into isotonic sodium citrate—3.8 per cent. The amount of this solution—160 c.cm.—contains 6 grams of sodium citrate, which has no harmful effect. When a good blood flow is maintained through a needle of adequate calibre and the blood and citrate are well mixed, as large a quantity as 800 c.cm. blood may be obtained by this method.

A series of forty-four citrate transfusions were given under rush conditions at a casualty clearing station with good results. The immediate effect of the transfused blood and subsequent progress of the cases were fully as good as that seen following ordinary transfusion. No reactions of any consequence were observed.

DESTRUCTION OF NITS OF THE CLOTHES LOUSE BY SOLUTIONS OF CRESOL-SOAP EMULSION AND LYSOL.

BY

A. W. BACOT,

ENTOMOLOGIST TO THE LISTER INSTITUTE OF PREVENTIVE MEDICINE,
AND

LIEUTENANT L. LLOYD, R.A.M.C.,

CHIEF ENTOMOLOGIST OF NORTHERN RHODESIA.

THESE experiments were carried out with a view to assisting officers in charge of baths and wash-houses where the clothes of infected troops are treated in order to rid them of lice. From conversations with officers in charge of these establishments it appears that a precautionary measure frequently employed is to steep infected garments in a vat containing solutions of cresol-soap emulsion. There exists, however, some uncertainty as to the strength of the solution and period of immersion necessary to destroy the nits of *Pediculus humanus*. In this connexion it may be pointed out that overlapping methods of disinfection should if possible be avoided in the interests of economy. Hot water or dry heat at 55° C. destroys both nits and active lice within thirty minutes, even when protected by a covering of khaki cloth; while, if the temperature is raised to 60° C., fifteen minutes suffice. If at any period during the process of washing or drying garments they are subjected to the temperatures and periods above given, chemical solutions are unnecessary; if, on the other hand, the garments are steeped in effective chemical solutions, then it is unnecessary to use temperatures so high as those mentioned for washing or drying.

In utilizing the results of the present experiments for practical disinfection it must be borne in mind that solutions of both cresol-soap emulsion and lysol degenerate in their effectiveness for the destruction of bacteria in relation to the organic matter with which they become charged during use, and it is probable that a somewhat similar fall in their effectiveness for the destruction of nits may occur. It has not been possible, so far, to ascertain if this probable drop in efficiency occurs, owing to our lack of knowledge of the exact condition of use. If samples of solutions actually employed could be forwarded to the Lister Institute, with the necessary data as to strength and the relations of quantity of fluid and period of use, and the number of garments treated, it would be possible to carry out the experiments necessary to obtain information on this point.

METHOD OF TEST.

Pieces of army shirt flannel on which numerous nits had been laid were immersed in the solutions for the periods shown in the accompanying tables; they were then taken out, and the superfluous fluid removed by placing on filter paper for a few minutes. After this they were placed in small entomological boxes lined with a strip of dry flannel, and carried in a thin cotton bag, suspended from the neck between skin and shirt, to incubate.

On examination of the tables it will be noted that the lysol (crude carbolic acid and soft soap emulsion) solutions are decidedly more effective than the cresol-soap emulsion solution at the higher temperature but less so at 32° F. Why this should be the case is not evident. The difference

in the latter case is not great, and may possibly be largely, if not entirely, a matter of chance, dependent upon uncertainty of action at low temperatures.

An interesting feature of the series is the regular rise in the percentage of lice which die while hatching as the action of the solutions become less fatal up to a mid point, when it again declines to a minimum in proportion as the hatching ceases to be checked owing to the weakness of the solutions. It is a matter of question whether death during escape from the egg is due to the action of the fluids on the eggshell, or to a want of robustness in the larvae.

The evidence as a whole seems to establish the fact that steeping for twenty minutes in a 2 per cent. solution, either lysol or the cresol soap, is quite effective provided the temperature is not below 50° F.

A PLACARD is to be posted in the offices of town and country clerks in the State of New York stating that no marriage licence will be issued until both parties make the following statement on oath: "I have not to my knowledge been infected with any venereal disease, or if I have been so infected within five years, I have had a laboratory test made within that period which shows that I am now free from infection from any such disease."

SOME SIMPLE HOT AIR APPLIANCES FOR FIELD UNITS.

By LIEUT.-COLONEL C. MAX PAGE, R.A.M.C., S.R.

THE rapid transference of the wounded from such organizations as regimental aid posts and advanced dressing stations to the active surgical centre at the casualty clearing station is one of the principal problems which confronts medical units in the forward areas. During this period of transport the main difficulty with which the medical officer has to contend is shock; and once the wounds have been protected and any fractures satisfactorily splinted, his efforts are directed to keeping up or improving the general condition of the patients. The maintenance of body heat plays a most important part in this respect, and is a matter which, if neglected at this stage, may prejudice the whole later course of the case by leaving the man unfit for the essential operation at the casualty clearing station. Various schemes to this end are already in use, but I think it is worth while to describe some apparatus which has proved of practical value in dealing with the problem. More elaborate and capacious plant can be designed on the same principles under stationary conditions, when time and labour are of less account. That described below is essentially portable, and can be made up by any practical man from material ready to hand.

The first need is for some means by which a constant supply of dry and warm blankets and pyjamas can be maintained, and for this purpose a blanket drying chamber is used.

Blanket Drying Chamber.

The apparatus consists of a frame 32 in. square built of 3 in. by 2 in. wood. Two sides are tenoned and the others morticed (Fig. 1); on one face of the two morticed sections

FIG. 1.—Plan of blanket rack, 32 in. square. The main frame is made of 3 in. by 2 in. wood. The central rails form a continuous length of wire or cord wound through the slots in the side members. The outer rail is made of wire or standard splinting.

are cut, at regular intervals, twelve slots half through the wood and wide enough to take ordinary telephone wire. The frame is carried as a bundle of sticks. For use they are fitted together to form a square frame. This is kept firm by lacing with a continuous cord or wire around the slots to form the rack, as shown in the drawing. The wood should be so cut that there is a ½ in. projection of the tenoned and morticed ends; a groove is cut in the middle of these projections and another wire passed round the whole frame through them to form a surrounding rail; if preferred, this rail can be made of aluminium or steel splinting (from fracture box).

To form a drying chamber the frame is suspended by cords in a horizontal position (or supported on a light stand) about 5 ft. from the ground. Blankets folded to fit are hung over the surrounding rail and fixed with a few pins. These blankets are so arranged as to form four complete sides of a box (with blanket walls). The floor will form the bottom, and another folded blanket is placed over the rack, after objects to be dried have been hung on the wires, to form the top.

Two Beatrice stoves, with a simple tin baffle plate to protect the flame, are put on the floor inside the box as the

source of heat. In use no obvious air entry or exit should be left. Under average conditions (with two double-wick stoves) the temperature inside the blanket chamber is raised to about 120° F. in twenty minutes; at this stage, when the apparatus is in use for ordinary drying, the roofing blanket is pushed a little on one side to allow of ventilation, and the contents will then rapidly dry off. If the contents are very wet the temperature in the chamber should be raised higher before free ventilation is allowed.

Simple suspension of the frame, as described above, is the most practical arrangement for forward area work; under stationary conditions it may be supported on a skeleton stand.

Use as a Hot Air Sterilizer.

The same apparatus can be used for sterilizing small batches of clothing when a steam disinfectant is not available. The chamber should then be formed by at least a double fold of blanket all round, and three Beatrice stoves used. With this arrangement the temperature in the chamber can be raised to about 200° F. in twenty minutes. An exposure to this temperature for half an hour will kill lice eggs and the scabies parasite, as the garments, turned inside out, or blankets, being suspended, have their surfaces well exposed. This method does not damage the leather of breeches.

Hot Air Generator.

In an advanced dressing station the first method for raising the wounded man's body temperature is the hot air bath. For this purpose a hot air generator, as shown in the figure, is convenient (Fig. 2). It is made from a standard biscuit tin, or a four-gallon petrol tin; the latter is the stronger. The side of the tin is cut away except for a strip about an inch wide at the top, and a door may be put in the gap so made. The top is cut out and a domed cap fitted in its place. Into one side of the domed cap a short length of tin pipe is set, and a further series of lengths of tin pipe,

FIG. 2.—Heat generator made from biscuit box or four-gallon petrol tin.

prepared so as to telescope together, form the delivery pipe; the right angle bend is formed by an elbow of the ordinary pattern French stove piping. Solder, though useful for finishing off the dome, should not be relied on for the fixation of any part. If available, sheet asbestos may be applied to the dome and elbow. The addition of handles to the sides of the box is convenient. A double-wick Beatrice stove is placed in the box as a source of heat. The Primus pattern of stove is less reliable, and is not altogether safe for use in the closed apparatus described.

To give a bath, a properly blanketed stretcher on trestles is used, and an air chamber formed over the trunk of the patient by means of a simple cradle (Fig. 3), the whole

FIG. 3.—Skeleton cradle for hot-air baths. Made from aluminium splinting.

being covered by two or three blankets. The cradle frame may be made of skeleton splinting from the field fracture box or of stout wire. This arrangement allows dressings or operations to be carried out on the extremities while the heat is being applied. The box containing the stove is placed under the middle of the stretcher, and the piping arranged to deliver hot air just above the stretcher level. The box and contents are thus well out of the way, and only the pipe elbow projects from beyond the stretcher pole. With this apparatus a hot-air bath of from 130° F. to 300° F. can be given. For the wounded man a fifteen minutes' bath at about 130° F. is, I think, most satisfactory. The high temperature bath should be reserved for the treatment of urinary cases or myalgia under stationary conditions.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DISORDER OF THE RIGHT EXTERNAL SEMICIRCULAR CANAL.

THE two following cases, which present many points of similarity, are of interest:

1. A young woman who had previously suffered from three attacks of retrobulbar optic neuritis, after partaking at breakfast on January 15th, 1918, of rolled ham, which was noticed to be of unusual colour and from which fat was absent, found herself on the way to business falling towards a friend on her right. She struggled against this symptom and giddiness during three days. Then vomiting set in. When seen, there was constant lateral nystagmus. The patient could not stand unsupported, and there was vomiting of cerebral type. There was no deafness to speech test, and no tinnitus. The reflexes of the lower limbs were normal. Twelve days later the nystagmus could be barely elicited; the patient could walk and stand. The condition was that of one after nine days in bed.

2. A man aged 53, after partaking at breakfast on January 26th of ham which was noted to be watery, went to business. Some three hours later he suddenly collapsed on to the floor of his office. He was removed home. His gait as he was helped was to the uninitiated that of a drunken man, and many have been the jokes at his expense. Seen five hours later, he was retching and vomiting mucus like an alcoholic in the early morning; he is not alcoholic. Nystagmus, lateral, was most marked. He could not stand or walk unaided. There were no subjective aural sensations, nor was there any deafness to speech. Now, eighteen days after the onset, there remains only slight incapacity for mental activity. During a week there was slight hissing tinnitus, and for a few days there was a distinct tendency to fall to the right.

In neither case was there paralysis of cranial motor nerves, nor drowsiness, nor any definite ptosis.

H. D. O'SULLIVAN, B.A., M.B., B.C. Cantab.

Burton-on-Trent.

THROUGH-AND-THROUGH RAMROD WOUND OF HEAD.

On November 9th a girl, aged 8, was brought to me with the ramrod of a gun fixed firmly in her head. It appears that a gun had been left on a shelf, loaded with the gunpowder charge only, and the ramrod left in it. The child in pulling something off the shelf had caused the gun to fall forward, when it went off. The ramrod had entered the cranium one inch above the top of the forehead, half an inch to the left of the middle line, and was protruding for some four or five inches from a point half an inch to the right of the same line and two and a half inches above the occiput. On admission the child was conscious, but the pulse was scarcely perceptible. There was no bruising of the skin, nor any haemorrhage, and the ramrod was so firmly fixed in the skull that the point had to be sharply tapped with a mallet in order to loosen it sufficiently to allow of its withdrawal. For

this the child was given chloroform and the head shaved and the protruding end of the ramrod was painted with iodine before putting it back through the skull. Very slight haemorrhage at the point of exit followed the withdrawal. For the first two days the patient vomited when any food was given her by the mouth, and for the first day the pulse was very slow (48) and intermittent. By the morning it was regular and of good volume. The temperature was 100.8° on the first night, but by the morning of the second day both pulse and temperature were normal. During the next few days the pulse was occasionally irregular, and she complained a good deal of headache, but otherwise she made an uneventful recovery. The little punctured wounds healed in two or three days by first intention, and she was dismissed in perfect health in three weeks, having been kept in hospital long enough to make sure that no cerebral symptoms would develop later. The illustration shows the top of the head with the ramrod *in situ*.

Reports of Societies.

PATHOLOGY OF MALIGNANT GROWTHS.

A MEETING of the Pathological Section of the Royal Society of Medicine was held on April 16th, when Professor W. BULLOCH, F.R.S., President, was in the chair.

Tumours Arising in Endothelium.

Dr. E. H. KETTLE, in a paper on this subject, said that such tumours were not easy to recognize, as the neoplastic endothelial cell presented no distinctive characters. Some of the accepted diagnostic features were: An undifferentiated polymorphic celled type of growth; a whorled arrangement of the cells with the formation of giant cells; the close association of the tumour cells with blood vessels; and the occurrence of narrow trabeculae or elongated channels, which might contain blood. Some of these features might equally be applied to carcinomata; others appeared to have been accepted with very little critical examination. The author had as yet examined in detail only two specimens.

1. A malignant endothelioma in a woman, aged 44, who had suffered from elephantiasis of the right leg since childhood. In 1914 the limb became extremely painful; several silk drains were inserted, but amputation was performed in 1915. Recurrence ensued, and the limb was amputated through the hip-joint. Histologically the growth consisted of alveoli of cells of very irregular shape, combined with large spaces which contained fluid blood. Clear indications could be seen of its origin, especially at the periphery, where the tumour cells occurred as branching syncytial masses closely resembling vaso-formative cells, or as endothelia lining vascular spaces. A constant feature was the formation of vacuoles in the cells, and it was by the confluence of neighbouring vacuoles that the larger spaces were formed. Blood was extravasated into the spaces from involvement and rupture of capillaries in the stroma.

2. A small infiltrating growth attached to the outer margin of the left erector spinae in an infant; this showed clearly capillary formation by vacuolation of the tumour cells, and the origin of the cells of the neoplasm from the endothelium of long complex capillaries, which established communication with healthy veins.

Autologous Grafting of Malignant New Growths in the Mouse.

Dr. J. A. MURRAY showed a series of charts illustrating the typical sequences which are met with in autologous grafting of malignant new growths of the mouse. In a series of 405 experiments 302 positive results were recorded. Of the 103 negative autoinoculations death occurred in 53 before the lapse of four weeks, and could be ignored as delay for this period was common. The significance of the remaining 50 negative results (15 per cent.) was discussed. It was shown by a study of individual charts that the negative results might be due to a variety of extrinsic causes apart from lack of vitality in the cells of the graft. The conditions of experiment made it impossible to utilize negative results in individual cases. The occurrence of delayed positive results made the method quite unsuitable for diagnostic purposes in the human subject.

TREATMENT OF SYPHILIS.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, on March 22nd, the President, Dr. HENRY O. DRURY, in the chair, a discussion on the treatment of syphilis was opened by Dr. T. PERCY KIRKPATRICK. After insisting on the importance of early treatment, he said that efficient treatment included the administration of salvarsan or some analogous drug. He had himself followed the procedure recommended at the Military Hospital, Rochester Row, using either kharsivan or diarsenol, and had no doubt that the procedure was efficient. But the question arose whether treatment by galyol or some of the other preparations might not be as good or better. In the treatment of some patients in the early secondary stage, and in practically all in the late secondary or tertiary stages the course of treatment had to be much longer than when it was begun in the early stages. He had followed the plan recommended at Rochester Row of courses of salvarsan accompanied by mercury, repeated till a permanent negative Wassermann reaction was obtained. Some patients actively treated until an apparent cure was effected—whose blood serum gave a persistently negative Wassermann reaction—afterwards developed such parasyphilitic affections as general paralysis of the insane and locomotor ataxia. In such patients the cerebro-spinal fluid continued, as a rule, to give a positive Wassermann reaction. It was doubtful whether a definite prognosis should ever be given without an examination of the cerebro-spinal fluid. In the course of his paper Dr. Kirkpatrick expressed his acknowledgements to officers of the R.A.M.C.

Major H. C. DONALD, R.A.M.C., who followed, said that the use of salvarsan combined with mercury had given very satisfactory results. Under mercury alone 83 per cent. of soldiers had been readmitted to hospitals, at least once during the first year, for relapse. Under salvarsan combined with mercury the percentage was less than 1.3. The latter statement was founded on the record of over 10,000 cases. Of the drugs in use in the army kharsivan, arseno-benzol, and galyol were the most usual, and had all proved successful; galyol had not been so efficacious as the other two, but it had the advantage that it was easily mixed and could be given intravenously with a Record syringe. It must be used at once, as it quickly became oxidized. Llargol, containing silver and antimony in combination, had been used recently with apparently good results, but their permanence could not yet be affirmed. At the beginning of the war the intravenous method of administration of kharsivan—allowing the solution to flow into the veins by gravitation—was most in use. Neo-kharsivan had given excellent results. Within the last year or eighteen months there had been a tendency to return to the intramuscular or deep subcutaneous injection, and he believed that some day it would prove to be the most successful and simple method, and well suited to dispensary practice. The objection was the amount of local pain sometimes caused. The addition of stovaine had not seemed to help much, and he preferred to mix the dose in 10 or 12 minims of distilled water, to diffuse as well as possible while injecting, and to massage the buttock well afterwards. The course at present in use in the army, as suggested by Lieut.-Colonel Harrison, R.A.M.C., was as follows:

Seven weekly doses of the arsenic compound selected were given intravenously, commencing with 0.3 gram for the first three doses, 0.4 gram for the next three doses, and then one dose of 0.5 gram, a total of 2.6 grams. If administered by the intramuscular method the doses were two of 0.45 gram, followed by five of 0.6 gram, a total of 3.9 grams. A weekly dose of 1 grain of mercury as cream was given by intramuscular injection. If at the end of the course the blood reaction was negative the patient was directed to have a blood test made at the end of two, four, six, and twelve months. If the reaction was positive or doubtful the man was put on a course of potassium iodide for fourteen days, and then given two weekly doses of 0.3 and 0.4 gram of the arsenical drug and 1 grain of mercury. Tertiary cases received the same course, repeated after intervals during which potassium iodide and mercury were administered. It was necessary to determine repeatedly the Wassermann reaction of the cerebro-spinal fluid before pronouncing a patient cured.

Major Donald had not seen many cases of syphilitic diseases of the nervous system in the army during the war, but had been struck by the marked improvement of

symptoms under salvarsan and mercury. He related the following case as an instance:

A discharged soldier, aged 49 years, but looking much older, with marked signs of tabes, practically crawling, with loss of control of bladder and rectum, presented himself for treatment, giving a history of syphilis contracted nine or eleven years before. He was treated as an outdoor patient after being detained a couple of days for spinal puncture—Wassermann positive. He was put on potassium iodide for a fortnight, and then attended weekly for kharsivan and mercury. The drug was given intramuscularly; after five injections he was walking much better, and had recovered the control of his bladder and rectum, was in good health, and looked much younger.

Major Donald thought that all cases of parasyphilis of the nervous system should be treated by salvarsan and mercury, even though at times the treatment seemed to aggravate the symptoms. He would begin by giving a course of potassium iodide and mercury for a fortnight, and then doses of 0.1, 0.2, 0.3 gram salvarsan weekly, allowing fourteen days' rest between each seven injections until four to five grams had been reached. Potassium iodide should be given in the intervals.

Captain H. S. LAIRD, R.A.M.C., said that he preferred the intravenous method of injection, on account of the pain and the liability to abscess which followed the intramuscular method. Mr. G. PUGN MILDON considered that the treatment should continue for three months; three weekly injections of salvarsan should be given and then three at fortnightly intervals, combined with mercury during the whole period. He believed that if parasyphilitic diseases were treated early, that is to say, before actual destruction of the nerve cells and while the disease was still confined to the vascular and intercellular tissues, good results might be expected.

Rebicus.

BLOOD PRESSURE.

THE third edition of NORRIS's textbook on *Blood Pressure*¹ is in every way a most complete and admirable work. After an account of the physiology, which, with the chapter on the venous pressure, is contributed by Dr. J. H. Austin, a fully illustrated description is given of the various forms of sphygmomanometers, and for ordinary work Nicholson's new instrument, a portable mercurial apparatus enclosed in a metal case, is recommended. The five phases of the auscultatory method, described by Korotkow in 1905, and introduced to the notice of the profession in this country some years later by the late Dr. George Oliver, are explained and illustrated by diagrams; this method is simple, rapid, and accurate, gives the diastolic as well as the systolic blood pressure, and among those familiar with it has supplanted all others for clinical work. Although those interested in blood pressure estimations may regard this as a truism, we believe that its adoption by those who possess and often use a sphygmomanometer is not so general as the value and easy application of the method deserve.

While admitting that there is no entirely satisfactory blood-pressure test for determining the functional efficiency of the circulation, the author considers that some of those described may throw some light on the question; he has used extensively Crampton's test for vasomotor efficiency, and places some reliance on its results. It consists in a comparison of the pulse-rate and systolic pressures in the lying-down and in the erect postures, there being normally an increase of about seven beats a minute and 10 mm. Hg in the latter. The systolic and diastolic pressures being commonly 120 and 80 with a difference, or pulse pressure, of 40, the "cardiac load" has therefore been considered to be $\frac{2}{3}$, or 50 per cent. of the diastolic pressure; in hypertension this pulse pressure percentage of the diastolic pressure may be greatly raised, and prognostic importance has been ascribed to it; but the author has not found "the cardiac load" of any value in the estimation of circulatory efficiency. A systolic pressure constantly at 160 mm. Hg or above, and a diastolic of 100, is regarded as definitely pathological at

any age, and as the diastolic is far less subject to temporary variations and a better index of the mean pressure than the systolic, it is often the more important of the two; thus a constant diastolic pressure of 100 mm. Hg indicates high blood pressure, whether the systolic is 180 or 140.

The thoroughness of the review of the whole subject is further shown by the summaries of the changing phases of opinion as regards the significance of blood pressures in various conditions; thus the view that a low blood pressure exists before the appearance of physical signs of tuberculosis is rendered more than doubtful, the author quoting Janeway's observations, and concluding that hypotension is seen in the later stages when it is due to toxæmia, and that the stethoscope is a much better means than the sphygmomanometer for diagnosing incipient tuberculosis. Again, Gibson's law, that when the blood pressure expressed in millimetres of mercury does not fall below the pulse-rate the prognosis of pneumonia is good, and conversely, is certainly far from infallible. Enough, perhaps, has now been said to show the character of this valuable book of reference, and it need only be added that it is well written and appropriately illustrated.

HEWLETT'S "BACTERIOLOGY."

SINCE its first appearance twenty years ago Professor HEWLETT's admirable *Manual of Bacteriology*² has been in constant demand and now is in its sixth edition. As the fifth edition came out in 1914 many changes have been necessary, and these have been incorporated clearly and succinctly, as is seen in the sections on septic wounds and gas gangrene. In the section on spirochaetosis icterohaemorrhagica the mode of infection is said to be uncertain, probably by water or by contact, possibly by insects, and no mention is made of rats. The work is so fully up to date as a whole and is so clearly written that it may be confidently recommended to the student as well suited to his needs.

NOTES ON BOOKS.

THE small book on the irrigation of wounds by the Carrel method, by J. DUMAS and ANNE CARREL,³ a short review of which was published in the *JOURNAL* of March 31st, 1917, p. 426, has been translated by Dr. A. V. S. Lambert, of Columbia University, New York, and issued with an introduction by Dr. W. W. Keen. It was intended by Madame Carrel primarily for the instruction of nurses, but it will be found useful by surgeons also who wish to make themselves acquainted with the details of the method.

Dr. TINEL's excellent manual of *Nerve Wounds*⁴ has been translated from the French by Mr. ROTHWELL and Mr. JOLL. The original work was reviewed in the *BRITISH MEDICAL JOURNAL* of September 30th, 1916 (p. 465). The translation has been well rendered and printed.

The second edition of *The Panel Doctor: His Duties and Perplexities*,⁵ by Dr. T. M. TIBBETTS, has appeared. The first edition, reviewed in our columns of February 10th, 1917, was, we learn, very quickly exhausted, and the author has taken the opportunity of revising the matter and bringing the subject generally up to date. The book has proved very useful to medical practitioners working under the Insurance Act, and we again commend it to their attention.

The *Minutes* of the General Medical Council for the year 1917 have been issued in a volume (Constable, 12s.), which contains also the minutes of the branch councils, of the executive and other committees, and various reports,

¹ *Blood Pressure: its Clinical Applications*. By George William Norris, A.B., M.D., Assistant Professor of Medicine in the University of Pennsylvania. Third edition. Philadelphia and New York: Lea and Febiger. 1917. (Med. 8vo, pp. 413; 110 figures, 1 coloured plate. 3.50 dollars.)

² *Manual of Bacteriology, Clinical and Applied*. By R. Tanner Hewlett, M.D., F.R.C.P., Professor of Bacteriology in the University of London. Sixth edition. London: J. and A. Churchill. 1913. (Pp. 769; 31 plates and 69 figures in the text. 14s.)

⁴ *Nerve Wounds: Symptomatology of Peripheral Nerve Lesions Caused by War Wounds*. By J. Tinel, Ancien Chef de Clinique et de Laboratoire de la Salpêtrière. Authorized translation by Fred. Rothwell, B.A. Lond. Revised and edited by Cecil A. Joll, M.B., M.S., B.Sc. Lond., F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1917. (Sup. roy. 8vo, pp. xii+317; 323 figs. 15s. net.)

⁵ *The Panel Doctor: His Duties and Perplexities*. By T. M. Tibbetts, M.D., M.R.C.S., L.R.C.P., D.P.H. London: John Bale, Sons, and Danielsson, Ltd. 1918. (Cr. 8vo, pp. 59. 2s. 6d. net.)

including that of the Education Committee. The *General Index* to Volumes XL to LJV (1903-1917) has also been issued (2s. 6d.). A prefatory note states that the number of entries has been curtailed where experience has shown that this can be done safely without impairing the usefulness of the publication.

DIETARIES IN THEORY AND PRACTICE.

VISCOUNT DUNLUCE and Captain M. GREENWOOD have written a very interesting report of an inquiry into the composition of dietaries, with special reference to the dietaries of munition workers. The work was carried out under the supervision of the Food Investigation Committee appointed by the Minister of Munitions, and the report is published by the Medical Research Committee.¹ It is prefaced by a valuable sketch of the evolution of scientific opinion on the physiology of diet and metabolism, beginning with the researches of Voit in the early seventies. It appears that the literature on this subject is riddled with the results of quoting at secondhand without verification at the fountain head.

From the mass of information digested by them the authors conclude that the increase in demand for energy with increasing muscular work, the body weight of the subject being known, can be determined with fair accuracy, but only within comparatively narrow limits, and that no conclusion can be drawn as to the requirements of a man doing sedentary work. Current dietetic standards of energy needs are ultimately based upon statistical averages deduced from a sampling of diets actually eaten, but their validity is finally established by exact experiments. Further, external conditions have an immensely important influence on the energy demand. The authors deal shortly with the protein question, summing up the spirit of modern teaching in an ingenious metaphor.

In the section on working-class diet statistics collected before the war they remind us that such data only give the quantities of food purchased, not the amount of food consumed. "Waste, in the culpable sense of deliberately spoiling or throwing away edible food, is of hardly more than rhetorical interest," but there is an unavoidable waste of calories and protein in the preparation of food, especially of food containing much fat. In comparing statistical diets with theoretical diets, the reader is advised to subtract mentally at least 10 per cent. from the former. Allowing for various sources of error, the authors think that the pre-war statistics fail to demonstrate any necessity for the average working man to consume a diet equivalent to more than 3,500 calories a day. Nevertheless, the heavy incidence of disease upon the poorer classes and the prejudicial effect of underfeeding upon resistance to infectious disease shows that it is not well to build much upon statistics.

The authors' special inquiry was made during the spring and summer of 1917 in the hostels and canteens serving the munition workers in various factories. The general results and detailed analyses are shown in tabular form. The circumstances under which the census was made were peculiar in three respects: there was an acute shortage of potatoes at the time, there was coincidentally an energetic "eat less bread" campaign, while sugar was very scarce. These three factors combined to lower the proportion of carbohydrates, and the *contre-coup* of the bread economy was a remarkable increase in the consumption of fat and an appreciable rise in that of protein. Had the slogan been not "eat less bread," but "eat more fat," the response, they think, would have been the same—a curious and instructive instance of what may happen when national habits are disturbed. With regard to potatoes the authors state that, as was pointed out in our columns some months ago, the existence of large stocks of potatoes in the country is, owing to transport difficulties, by no means the same thing as the availability of potatoes in industrial centres. Dealing with war-time German dietaries the authors conclude that the German working man has been decidedly worse off than the English labourer since the war, and even since the intensive submarine campaign and the increasing world-shortage of foodstuffs; but the extent to which the German civilian population has suffered in health, and therefore in efficiency, from shortage of food is uncertain.

The authors' investigations afford no reason to suppose that those who served the nation in munition factories last year had any cause to complain of the provision made to sustain their physical strength and health. But time will force changes upon the nation; the provision of so many calories from fat and meat which could be made six months ago, is now no longer feasible. Happily, economic necessity and the teaching of physiology, tentative though the latter may be, seem to point in the same direction. The substitution of energy derived from potatoes and cereals for a large proportion of that yielded by fats and animal proteins, while involving hardship, cannot scientifically be condemned; and the lesson seems to be that popular tastes and prejudices are rooted more in social habit than in basic physiological demands.

As the Medical Research Committee points out in its introduction, this report not only supplies data of primary importance to those who have to solve the social and administrative problems of rationing the civilian forces of this country, but adds definitely to our general knowledge of the actual dietaries of the population. The coming of war caught the study of nutrition in a period of great activity in the collection of new facts; the sudden and exceptional demand for practical guidance found many gaps in the body of dietetic knowledge available for practical use. When the food shortage became imminent physiologists were able in some degree to state in quantitative terms the actual energy consumed in various kinds of productive work, but they could not assess at all fully the adaptability of the human machine to new and presumably less favourable conditions. As a guide to the application of existing knowledge as a whole to the problems of practice the present report should be of the utmost service.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee twenty-six cases were considered, and £278 voted to twenty-three of the applicants. The following is a summary of some of the cases relieved:

Widow, aged 68, of L.S.A.Lond. who died in 1907. Present income from investments £22 4s. 11d., which is much less now. Has tried to supplement this by taking in paying guests, but not successfully. Requires help towards expenses. Voted £12 in twelve instalments.

Widow, aged 40, of a surgeon in the Royal Navy who died in 1906. Was left with three children, aged now 22, 16, 14. Income from pensions £98, investments £15, and receives £40 a year as matron of a boys' school. Desires help towards education of her son. Voted £5, and referred to the Guild.

Daughter, aged 77, of M.D.Glasg. who practised in London and Glasgow. Applicant's income from dividends £44, and she has one boarder at 17s. a week. Her main income is derived from letting her cottage furnished during the summer, but since the war has not been successful. Rent and rates £37. Voted £15 in twelve instalments.

Daughter, aged 49, of M.D.Glasg. who practised at Bawtry and died in 1872. Prior to the war was able to make a living by taking in paying guests, and as her house is on the East Coast she has had none since September, 1915. Lives in own house, and pays £8 for rates. Is now doing a little clerical work, but this is not sufficient to keep her. Relieved three times, £30. Voted £10 in two instalments.

Daughter, aged 51, of M.D.Dubl. who practised in England and died in 1904. Applicant had a school for some years, but is now completely blind in one eye, and has almost lost the sight of the other, and had to give it up. Has a small pension from a blind society, and help from the Guild. Relieved twice, £25. Voted £18 in twelve instalments.

Daughter, aged 60, of M.R.C.S.Eng. who died in 1873. Applicant has no means, and suffers from rheumatism. Entirely dependent on sister, who cannot afford to keep her. Relieved thirty-four times, £278. Voted £12 in twelve instalments.

Subscriptions may be sent to the Acting Honorary Treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand clothing and household linen. The class of clothes most wanted is that suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

¹ Special Report Series, No. 13.

British Medical Journal.

SATURDAY, APRIL 27TH, 1918.

THE BUDGET.

DURING the first two years of the war, taxation increased at half-yearly stages, but the taxpayer is now apparently considered sufficiently hardened to be able to dispense with this particular method of tempering the wind for the time of shearing. We are, of course, assuming that there will be no second Budget for this year, and in view of the very heavy extra taxation proposed—£114,000,000 in addition to the new luxury tax—few will feel inclined to doubt the validity of that assumption.

The old adage, "il n'y a que le premier pas qui coûte," has, like many others, been completely reversed in this war, and the Chancellor's statement reminds us that in the financial as well as in the military world the severity of the struggle is intensified with the progress of the months, and that even the close of the war will leave us to face a period of grave difficulty. The huge sums borrowed in this country are to a large extent spent here in the manufacture of munitions, including the multifarious equipment of our own armies and those of our allies, and the abundance of money and the almost universal prevalence of war bonuses, foster a feeling of prosperity which is reflected only too thoroughly in the spending habits of the great majority of the people. The after-war transition period will test our powers of organization to the utmost, and the necessity for a sound and far-seeing financial policy arises very largely from the fact that it would be almost impossible for any government to deal with the post-war industrial and social problems and at the same time to increase taxation to cover current expenses.

The declared policy of both Mr. Bonar Law and his predecessor has been to maintain permanent, as distinct from temporary, taxation at such a level as to produce sufficient revenue to ensure that if the war comes to an end at the close of the financial year, the normal expenditure and the debt charge can be met without new borrowing or taxation. In an interesting passage he compared the policy of the German Government in this matter with our own, pointing out the widening margin between the German revenue and annual debt charge, and expressing the opinion that it was due to the fact that the wealthier classes in Germany held the political power and that the German Government were "absolutely afraid to force taxation upon them."

An examination of the Chancellor's proposals for raising the additional revenue necessary if our financial policy is to be continued, shows that in the main he has followed fairly closely the precedent of the past few years—it was put into operation in this country for the first time on a great scale in 1909—namely, that of looking to the wealthy class for the chief part of the revenue, and redressing the balance by indirect, and if possible direct, taxes on other classes, including the industrial worker, accepting gratefully the yield of such taxes but not perhaps regarding them as of primary importance from the point of view of the Exchequer. For instance, on this occasion the full rate of income tax is raised from 5s. to 6s. in the £, the super-tax and the death duties are increased, and a further attempt is made to bring

a bigger proportion of the large agricultural profits within the income tax net, while on the other hand further indirect taxes are imposed on sugar, tobacco, spirits and beer. One feature worth noticing is that, as regards income tax, the man whose total income is not greater than £500 is no worse off than before: in fact, if he is in a position to claim the new allowance of £25 in respect of his wife he will pay less. The further extension of the allowance in respect of children is a welcome sign of improvement in the incidence of the tax. The allowance was originally restricted to incomes which did not exceed £500 and amounted to £10 only; it now applies up to incomes of £800 and to the extent of £25; when any further change is made we hope that the restriction dependent on total income will be swept away, and that the amount of the allowance will be made to increase with the amount of the income—if a working man is fairly entitled to a deduction of £25 for a boy who in present circumstances is probably earning almost enough to support himself, it would seem reasonable that a professional man, who is keeping his son at school to the future good of the country, should have at least an equivalent or greater relief.

We note with pleasure that, though the rates of income tax on earned and unearned incomes exceeding £500 are to be increased, the rates for army and navy pay will remain as before. Even at that level they press heavily on scales of pay fixed originally with regard to pre-war conditions, but these are days when small mercies are more than ever welcome.

The most interesting of the Chancellor's proposals is the *ad valorem* luxury tax based on a levy of 2d. in the shilling for purchases of scheduled articles. The desirability of checking in some way the extravagance that undeniably exists—though not perhaps to the extent sometimes suggested—will be recognized as readily as Mr. Law's adroitness in leaving the schedules to be drawn up by a Select Committee of the House. The proposal breaks new ground in our fiscal system, and a thorough examination of the best method of collecting the tax will be essential; the experience of the French Government will no doubt point the way, but the trading methods of the two countries differ in several material respects, and much caution will be needed in approaching the problem. Given a sound system and a careful and willing administration, this new tax may quite possibly succeed in combining the virtues of both direct and indirect taxes while retaining little of their respective vices; in other words, it may become a valuable source of revenue, economical to collect and not burdensome to the payer; a hastily constructed or ill-considered scheme will court failure. From this standpoint it seems unfortunate that it was necessary to discuss the tax in public before it could be enforced; if it is now postponed for several months immediate buying of luxuries will "queer the pitch" for the new tax; on the other hand, if it is put in force quickly it may permanently suffer from a lack of foresight in its construction.

As we have already suggested, this Budget bears a family resemblance to its ancestors, and what we have said of them is true of this one, too—it takes the necessary money mainly from those who can afford to pay without acute suffering, but leaves out no one who can afford to pay anything worth collecting. No doubt a perfect system would relieve some and would tax others more heavily, but so far as the means at his disposal allow the Chancellor appears to have dealt out even-handed justice between various taxpayers. It remains for the latter to shoulder the burden with

what self-denial and fortitude they may possess, knowing that it is on the financial efforts of the country now that the future well-being of the nation will largely depend.

IF GOOD WHY NOT BETTER?

THERE was a letter in the *Times* on April 23rd which raised a point of some consequence, but in a way so confused and confusing that it may well have given the general public an erroneous impression. It dealt with the recent promotion of a number of medical officers to be major-generals. This promotion is, in fact, mainly a matter of terminology. The officers were all surgeon-generals before and ranked as major-generals. Their new titles do little more than bring them into line with officers in other branches. Technically all the surgeon-generals had ceased to belong to the R.A.M.C., the highest rank in which is lieutenant-colonel. An officer promoted to be colonel ceases, technically, to be an officer of the corps, which in this respect is regarded as though it were a regiment. The last point made by the writer may also be dismissed briefly. He is surprised that of eleven officers promoted nine came from Irish schools and only one each from England and Scotland. We have not verified his calculation, but assuming its correctness the explanation is simple. It is that at the time when these officers entered it the Army Medical Service was not popular in the English and Scottish medical schools. This unpopularity was, in the opinion of the British Medical Association, the Universities, and Royal Colleges in England and Scotland, well merited. These bodies combined to obtain reforms, the results of which are seen in this war, when for the first time in its history the Army Medical Service has won a success not surpassed, if indeed equalled, by any other branch of the army. The success is due partly to good administration, but chiefly to the application of scientific methods to the prevention of disease, and the surgical treatment of the wounded, which is mainly the prevention of wound infection—preventive surgery. The great merit of Sir Alfred Keogh, himself an Irishman, and of Sir Arthur Sloggett, his colleague in France, was that from the first they recognized that their true policy was to give as free a hand as seemed to them possible to the clinical physicians, surgeons, and pathologists who came forward to help the army. Unfortunately things did not move quite as fast at home as they did in France, and as we believe they have moved recently in the Mediterranean Command and in Mesopotamia, where bitter lessons had first to be learnt.

The regular Army Medical Service is still dominated, or was until very recently dominated, by the idea that seniority in the service meant competence, and that without seniority there could not be competence. There was this amount of justification, that the senior officers were the survivors of a much larger number who had been dropped by the way. But new conditions call for new methods, and the notion that only a senior regular officer can be a good administrator ought to be given up. The argument would seem to have been: such and such a berth at home is a surgeon-general's; which of the surgeon-generals shall have it? Some surgeon-general is appointed, even though he may have been tried and failed abroad. It is difficult to write about the matter without an appearance of animus, but the unfavourable impression these senior regular officers made, one after the other, when they appeared before the Select Committee on military recruiting medical boards

cannot be passed over or forgotten. The effect on the public mind was so unfortunate that the Secretary of State for War went down to the Committee one morning and announced that the Army Medical Service would cease to be responsible for the medical examination of recruits, and that the duty would be turned over to the Ministry of National Service acting through civilian medical boards. The Ministry of National service is now concerned also in the discharge of men from the army, but a cumbrous dual system is at present maintained.

Army medical administration was not successful at Gallipoli or in East Africa; it made a disastrous failure in Mesopotamia. It has been splendidly successful in France mainly, we suggest, because Sir Arthur Sloggett recognized the limitations of regular officers, and relied on physicians and surgeons and pathologists experienced in civil hospital work at home to settle certain principles of administration in consultation with him. It has achieved a large measure of success at home because Sir Alfred Keogh kept an open mind and encouraged civilian experts to give their best, as they were ready to do, in spite of the most discouraging obstruction in the Home Commands. We cannot see that the enemy activity on the Western front is any ground for delaying the institution of reforms at home. Rather is it an added reason for immediate action. We have no doubt that the new Director-General will receive valuable guidance from the highly competent Army Medical Advisory Board recently appointed.

It is a real misfortune, not perhaps so much for the Army Medical Service of to-day as for the future of the Royal Army Medical Corps, that there should be so much truth in the statement of the writer of the letter to which we have referred, to the effect that regular officers of the corps will leave, and are now leaving, the scientific—and, it may be added, the clinical—side for the administrative side, "as there, apparently, lies the only road to promotion." The courageous attempt to put the medical service of the Air Force on a sound footing as a scientific organization failed owing, if rumour speaks true, to the opposition of the Army Medical Department. But that is another story, too long and sad to tell now.

MEDICAL PRACTITIONERS UNDER THE MILITARY SERVICE ACT.

WE mentioned last week in a paragraph on this subject that the Central Medical War Committee was in conference with the Ministry of National Service and the Insurance Commissioners with regard to the position of medical practitioners under the Military Service Bill. The bill became an Act on April 18th, and renders liable to military service all medical men who had not attained the age of 56 at that date. The Ministry of National Service has undertaken to supply office assistance to the Central Medical War Committee towards carrying out the necessary arrangements, and a Government official to assist Dr. Cox in this way has been appointed by the Ministry, and will serve also as a liaison officer between the central professional committees and the Ministry. The official selected is Mr. S. P. Virian, who at one time was one of the senior clerks of the Insurance Commission and has more recently been employed in the Ministry of Food. Nominal lists of all medical men coming within the scope of the Act will be prepared according to areas, and arrangements will be made for their early physical examination by boards outside their own areas. They will be graded on ordinary lines and the professional committees will be able to obtain from the Ministry information as to the fitness

for practice of medical men in Grade 3. A certain number of those between 43 and 50 who are physically fit and surplus to local requirements may be sent directly into military service; but in general men over 45 will be urged to undertake substitution practice, to release for service fit men under 43. It is intended that wherever possible substitution shall be local and shall not involve the removal of a man from one area to another. A special inter-departmental committee will be set up to consider cases in which the adjustment of the interests of the Government departments concerned presents difficulties. The Local Arrangements Subcommittee of the Central Medical War Committee will continue its work on lines similar to those it has hitherto pursued. The Ministry of National Service will appoint medical men to visit areas and to advise the Local Medical War Committees and the central professional committees as to the rearrangement of civil practices and the transference of medical practitioners where this may be necessary. The reports of these officers will be made to the Ministry, but they will also be at the disposal of the central professional committees. These officers will attend the meetings of the Local Arrangements Subcommittee, and will, if required, submit to it reports on special areas which they have investigated. Representatives of the Ministry of National Service, the National Insurance Commissioners; and the Local Government Board, and other interested departments, will continue to attend the meetings of the Local Arrangements Subcommittee. A notification was issued by the Ministry of National Service on April 25th with regard to the calling up of older men under the Military Service Act, but it expressly states that it does not apply to medical practitioners, regarding whom special instructions will shortly be issued.

SOME MEDICAL ASPECTS OF AVIATION.

IN a pleasantly written article full of the experience gained at the Royal Naval Air Station, Dunkirk, Staff Surgeon S. F. Dudley,¹ R.N., though he never mentions the word, shows that he has a true insight into the psychology of the fighting aviator. The average flying life of these officers is very short, the wastage being mainly due to invaliding for loss of flying nerve, for they are of little use if they are not, to use their own language, "full on." The strain they are exposed to has manifold sources and falls on most of the senses in ways strange to the human machine with no heritage of experience in the air; in addition the loneliness, almost amounting to pain, when flying at high altitudes over the enemy's lines, and this is even worse over the sea, the extra work entailed by a spell of fine flying weather, the annoyance, to use a mild term, of anti-aircraft guns of foe and friend, must be taken into account. When, as a result of these and other causes, the pilot begins to calculate his chances and to lose confidence in his machine and his powers, he should be given sufficient leave, and it is essential that this should be managed before there are such definite signs as insomnia and tremor, otherwise he may never return really fit. But as the real aviator is the most courageous of men and, rather than run the risk of a suspicion of "cold feet," will carry on much too long, the medical officers endowed with sympathy and wise tact should be living in intimate contact with the aviators, and so with the help of the squadron commanders be in a position to detect the first signs of staleness and overwork and ensure a real and economical cure. It is not always enough merely to send the strained aviator to England or the country; many of them are colonials without ties or attractions in Great Britain, and to meet their needs a country club with plenty of sporting resources should be established. Leave, too, should be granted as occasion for it arises, and not merely at stated intervals, for in this way many more flying hours of better

quality will be secured and a true economy effected. Though on the whole temperate in alcohol, aviators smoke too much, especially cigarettes, and to obviate this habit that of chewing gum, so popular with many colonial officers, might, it is suggested, be more widely encouraged. When a crash occurs the other pilots and observers should be prevented from rushing out, as the sick berth ratings are competent to give first aid, to administer $\frac{1}{4}$ grain of morphine when necessary, and to convey the patient as rapidly as possible to the hospital. Wounds inflicted in the air usually do well, as infection is less prone to occur than in the trenches, and the pilot should descend at the nearest place where medical care is available and not return to a distant home. No aviator who has had malaria should fly until he has been free from recurrence for six months, for the conditions of chill and fatigue are extremely likely to cause a paroxysm. Many experienced aviators are ignorant of the relief given during and after a rapid descent by auto-insufflation of the Eustachian tubes. Unfortunately some pilots have an unreasonable prejudice against the use of oxygen, possibly bred of some irresponsible scoffer, and medical officers should therefore patiently explain in the mess or in individual talks the value of oxygen at high altitudes in preventing drowsiness and loss of rapid judgement and in accelerating reflex action.

GERMAN INFAMIES.

PROFESSOR GILBERT MURRAY, in his preface to an English translation of the memorandum by Prince Lichnowsky on his period as German Ambassador in London, makes a suggestion to account for the "strange brutalities and ferocities" of the Germans, especially German women, to prisoners captured at an early stage of the war which would save their ethics at the expense of their intelligence. He believes that it was due to their belief that the war was a treacherous attack, plotted in the dark by "revengeful France, barbaric Russia, and envious England." The emperor, the princes, the ministers, the bishops and chaplains, historians and theologians of Germany vied with one another in solemn attestations and ingenious forgeries of evidence, "and the people, docile by training and long indoctrinated to the hatred of England, inevitably believed and passionately exaggerated what they were told." But this explanation does not apply to the deliberate brutalities of the German authorities recorded in the report of Mr. Justice Younger's committee presented to Parliament this week. On February 7th, 1917, the British Government received from the German Government a note dated Berlin, January 24th. It complained that German prisoners suffered from inadequate food, defective accommodation (only tents being provided in many cases), and were subjected to hard work and to irregularities in the matter of their mails. The note went on to state that unless a reply was received from the British Government by February 1st, promising to remedy these alleged hardships, and to take measures to prevent German prisoners being again employed within 30 kilometres of the British front, a number of prisoners of war would be transported from camps in Germany to the area of operations in the western theatre of war, where, in respect of employment, accommodation, food, and mails, they would be treated in a manner corresponding to the practice of the British military authorities. It is now established that British prisoners of war were employed by the German Government within 30 kilometres of the firing line at least as early as July, 1916—that is, at least six months before the German note. An agreement was concluded between the British and the German Governments at the end of April, 1917, not to employ prisoners of war within 30 kilometres of the firing line, but British prisoners were so employed continuously down to, at least, February, 1918. It is also proved that on April 15th, 1917, British prisoners in German hands were told to write home that they would in future be subject to the

¹ S. F. Dudley. *Journ. Roy. Nav. Med. Service*, 1918, iv, 131-140.

following conditions: "Very short of food, bad lighting, bad lodgings, no beds, and hard work beside the German guns, under heavy shell fire. No bed, no soap for washing or shaving, no towels or boots, etc." As early as February, 1917, the German Government had been informed that 75 per cent. of German prisoners in British hands were accommodated in huts, and the remainder, as in the case of very many of the British troops, temporarily in specially warmed tents, provided with floor boards, and an ample supply of blankets. The postal arrangements worked perfectly, and strict orders had been issued that prisoners should not be employed in handling munitions or within range of the enemy's artillery. Only one casualty among them had occurred—a man who was wounded by a shell which must have been fired at exceptionally long range. The evidence is conclusive that the Germans have continuously employed British prisoners close behind their front, and within easy reach of shell fire, in digging trenches, loading munitions, and doing other military work. These men were, and no doubt, still are, half starved, the ration for a day consisting of $\frac{1}{4}$ lb. black bread, with coffee in the morning, soup at midday, and coffee again in the evening. The existence of these prisoners is concealed; they are allowed to write letters on printed forms dated from camps in Germany, but even these letters are not forwarded, and parcels do not reach them. At Limburg-aan-Lahn as late as November, 1917, there was an accumulation of between eighteen and twenty thousand parcels for British prisoners on the German western front which had not been delivered. One man who escaped from behind the German lines had weighed thirteen stone when captured; when he got back three months later he weighed eight stone. From a telegram in the *Times* of April 22nd, it appears that the *New York Times* has evidence that similar bad treatment is being meted out to American prisoners. The only ray of light throughout the report is in the evidence of a young wounded British officer in a ward of a German hospital in France. He said that the German university professor in charge of it admitted that he was ashamed of the "frightful" conditions to which his countrymen were subjecting prisoners. "The men were overworked, under shell fire, very much underfed, had not much clothing, and slept in sheds and shelters in the snow—filthy conditions." All were thoroughly ill treated behind the lines, and many died. By subscribing to the Hague Convention of 1907 the German Government entered into certain undertakings, two of which are thus stated in the German war book: (1) "Prisoners of war are protected against unjustifiable severities, ill treatment, and unworthy handling." (2) They "can be put to moderate work proportionate to their position in life. . . . These tasks should not be prejudicial to health nor in any way dishonourable, or such as contribute directly or indirectly to military operations against the Fatherland of the captives."

MEDICAL CERTIFICATES FOR NATIONAL SERVICE MEDICAL BOARDS.

THE Ministry of National Service has recently issued a leaflet to medical practitioners, dealing with certificates for men appearing before National Service Medical Boards. In the first place, it is stated that a well-drawn certificate from a private practitioner may be of great assistance to a Board, and receives full consideration before the Board gives its decision. All such certificates are either copied or filed for reference. A well-drawn certificate from the point of view of the Board is one which states name, age, and address of patient; date of last personal examination; length of time patient has been personally known to certifier; what diseases the latter has attended him for; patient's present physical condition; name, address, and qualifications of certifier. Such a certificate confines itself to matters which have actually come within the practitioner's personal observa-

tion and knowledge. If it be wished to draw attention to any other matter, such as the patient's statement about his previous medical history, the fact that it is based upon the patient's statement should be clearly indicated. It is particularly desired that the writer of a certificate should refrain from expressing any opinion as to the man's fitness or unfitness for military service. It appears that many certificates are still handed in to National Service Boards which do not conform to the type of certificate suggested, and even more certificates purport to prejudge a man's fitness or unfitness for military service. The circular ends by quoting from Sir Donald MacAlister's references in his presidential address to the looseness or irrelevance of statements in certain certificates which practitioners profess to attest by their signatures.¹

MEASLES AND PNEUMONIA IN CHILDREN.

A report has been issued by the Local Government Board on the prevention of mortality and disablement due to measles and pneumonia in children, by Dr. A. Salusbury MacNalty.² With regard to measles, Dr. MacNalty has collected and analysed much information bearing on pathology, clinical features, and treatment, on the circumstances determining death from this disease, and on practical measures for rendering it less fatal. This part of the report is prefaced by a memorandum by Dr. S. W. Wheaton, setting out in more detail the administrative measures which should be, and in some instances are being, taken by sanitary authorities against measles by providing for home visiting, adequate nursing, and medical attendance. The second part of Dr. MacNalty's report, on pneumonia in childhood, points to the need for further investigation of deaths from pneumonia complicating measles, for which purpose the information collected and analysed by him would form a useful preliminary. For the reduction of child mortality in pneumonia he believes that reliance must chiefly be placed upon the general measures of preventive medicine, especially those directed towards coping with the problem of infectious diseases, and upon skilled medical and nursing attention. Since bronchopneumonia is the most fatal complication, and the most frequent cause of death in measles, there is considerable advantage in bringing together in a single report the results of investigations, both statistical and clinical, into these two common diseases of childhood.

BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE subscriptions received by the Committee of the Belgian Doctors' and Pharmacists' Relief Fund during the last fortnight, in response to the second appeal, will enable the executive body to resume, though probably not on the original scale, the contributions which have been sent out to the committee of Belgian doctors and pharmacists sitting in Brussels for distribution among those most in need of help. The money received, however, will only restore for two months at most the possibility of sending a large monthly amount to the Brussels committee; hence further support is urgently needed. The anxieties of the present time, the vast increase in taxation, and the steady rise in the cost of living; make this an unpropitious moment for any charitable appeal, but we are sure that the medical and pharmaceutical professions in this country will do all that lies in their power to continue to aid their unfortunate colleagues in stricken Belgium. A much larger sum than has yet been obtained is necessary to make the present appeal a success. The executive committee will welcome regular monthly subscriptions from those who are unable to make a substantial donation; in this way the work could be kept going while time is gained for building up a capital sum.

We regret to announce the death on April 21st, at Looe, Cornwall, of Lieutenant-Colonel John Michell Clarke, R.A.M.C.(T.), M.D., F.R.C.P., physician to the Bristol General Hospital, and pro-Vice-Chancellor and Professor of Medicine in the University of Bristol.

Medical Notes in Parliament.

The Budget.

THE proposals contained in Mr. Bonar Law's budget speech on April 22nd were very favourably received by the House of Commons. To make good a deficit of 110 millions he proposed increased taxation, which in a full year will, it is estimated, bring in 114 millions. The principle upon which he proceeded was that it was a duty to levy now as much taxation to bear the current expenditure of the war as could be borne by the nation without weakening it in the conduct of the war. Even the Chancellor of the Exchequer was moved by the readiness with which all classes had been prepared to pay.

With regard to indirect taxation, his chief proposal was practically to double the duty on spirits and beer, the actual increase in the case of spirits being rather more than double. From this source he expected in a full year nearly 21 millions. He justified the increase in the duty on tobacco from 6s. 5d. to 8s. 2d. on the ground, firstly, that all persons did not regard it as a necessary of life, and, secondly, that the consumption had increased during the past year in spite of the high rate of the then duty; he hoped to obtain 8 millions from this source in a full year. By an addition to the duty on matches, which would raise the price to 1d. a box, he expected to obtain £600,000. An addition of 11s. 8d. a cwt. on sugar would yield in a full year just over 13 millions. He also proposed to impose a tax of 16 per cent. by way of stamps on luxury expenditure, but as the commodities to be so taxed are to be settled by a special select committee no estimate of the yield was given. The change in the postage rates is expected to yield 4 millions in a full year. For letters the new rate will be 1½d., but this will cover any package up to 4 oz. The lowest rate for parcels will be 6d., but this will carry 3 lb. Inland postcards will now cost 1d. The lowest rate for letters to the troops, to any part of the British Empire, and to the United States of America will be 1½d.; postcards will remain at 1d. With regard to income tax, the rate on unearned income is raised to 6s. in the £, and the estimated yield in a full year is 41 millions. No change is to be made in the existing rates up to £500, nor in the rate on the service pay of soldiers and sailors. The children's allowance will apply also to a wife. The allowance for children up to 16 years of age will apply to incomes up to £800 instead of £700. The super-tax is to be 4s. 6d. instead of 3s. 6d. in the £, and is to begin at incomes of £2,500 instead of £3,000. The estimated yield from this source in a full year is 14 millions. The general effect of the alterations is shown in the following table:

Income Tax.

Income.	Wholly Earned.		Wholly Unearned.		With Super-tax.		
	Amount.	Rate.	Amount.	Rate.	Income.	Amount.	Rate.
£ 550	£ 67	s. d. 2 5	£ 84	s. d. 3 1	£ 2,750	£ 868	s. d. 6 4
700	94	2 8	118	3 4	3,000	962	6 5
1,000	150	3 0	187	3 9	4,000	1,362	6 10
1,500	281	3 9	337	4 5	5,000	1,787	7 2
2,000	450	4 6	525	6 3	6,000	2,237	7 5
2,500	656	5 3	750	6 0	7,000	2,712	7 9

The White Paper containing the estimated cost of Services to be provided for in votes of credit (1918-19) has many points of interest, of which we can only note a few. The vote for the Ministry of Pensions is 41½ millions. Mr. Law said that the total required by the end of the year could not fall far short of 50 millions. The vote for the Ministry of Food is put down at nearly 7 millions. The expenditure on central and local offices is about one million. The total, which includes a sum of 5 millions in respect of potatoes, does not, it is stated, show the whole expenditure of the Ministry. The net expenditure on the Royal Commission on Wheat Supplies is 46 millions; this

sum includes a net loss of 40 millions on the sale of the 9d. loaf. The expenditure for the Central Control Board (Liquor Traffic) is estimated at nearly £700,000; of this £16,500 is in connexion with canteens and £647,000 is the net capital expenditure on direct control undertakings, less estimated receipts. The budget of the Ministry of Reconstruction is £26,400. Relief of British prisoners of war and British subjects in enemy countries represents £737,000, and the maintenance of conscientious objectors £116,500. The budget of the Ministry of National Service is nearly 3 millions; nearly the whole, it would appear, is expended in salaries and office expenses. Recruiting and registration are estimated to cost nearly two millions. The estimate for National Service medical assessors, which appears under the Local Government Board, is £7,500. Other expenditure of the Local Government Board is estimated at £95,000.

The Army Medical Service Report.—In reply to Major David Davies, on April 23rd, Mr. Macpherson said no decision had yet been reached with regard to presenting the report of the committee of inquiry into the medical service in France to the House, and that in the present circumstances consideration of the request had been suspended. Sir William Collins inquired whether, in view of the exceptional demands being made on medical men under the new Military Service Act, Mr. Macpherson would not consider the desirability of allowing those interested in the matter to ascertain from this report the way in which medical men were being used at the present time. Mr. Macpherson said he would consider that.

The Medical Profession and the Ministry of Health.—On April 22nd Mr. Booth asked the Minister of Reconstruction whether he had considered the position of the medical profession in relation to the proposed Ministry of Health; what decision had been reached as to a state medical service; and whether it was proposed to decide these matters whilst so many doctors were away serving with the forces? In a written answer Dr. Addison stated that the matter of a state medical service would not have been relevant to the conferences he had held as to the establishment of a Ministry of Health, with, amongst others, representatives of the medical profession.

Medical Examination of Older Recruits.—Mr. Gulland asked, on April 22nd, whether, in view of the necessity of more careful inquiry as to the health of the elder men to be called up under the new Military Service Act, the Minister of National Service would arrange that the opinion of the private medical attendants of called up men should be taken more fully into consideration. Mr. Beck replied that under the instructions issued to medical boards—National Service Regulation No. 24—which had already been published, the boards were directed to give full consideration to medical certificates given by general practitioners or consultants, and he had every reason to believe that this instruction was being fully carried out. The instructions also provided that where necessary reference might be made to the man's usual medical attendant. It was intended to issue further special instructions dealing with the medical examination and grading of the older men.

Prisoners in Turkey.—Mr. Hope stated in the House of Commons, on April 24th, that an agreement with the Turkish Government has been ratified, providing, by a relatively easy medical test, for the repatriation of all invalid combatant prisoners irrespective of rank, and of all members of the medical staff not required for the care of the prisoners who remain. Civilians will also be repatriated subject to certain qualifications. The agreement provides also for the inspection of prison camps by representatives of neutral powers, for better delivery of supplies and correspondence, for sanitation and opportunities for exercise, and for the mitigation of punishment.

Treatment for Discharged Tuberculous Soldiers.—Mr. Dnke informed Mr. Nugent, on April 22nd, that a proposal to relax the regulation prohibiting expenditure of the unexpended balance of the capital grant under the National Insurance Act, 1911, as far as might be necessary to provide accommodation in Great Britain for tuberculous men discharged from the army and navy, was under consideration. Any action to be taken in Ireland would be governed by the decision of the Government on the general question.

Medical Treatment of Soldiers' Widows and Children.—In reply to Major Davies, Sir A. Griffith-Boscawen, on April 23rd, said it was not within the competence of Local War Pensions Committees to make general provision for medical advice and treatment of the wives or widows and children of soldiers. Special cases in which there was pecuniary need could be met by grants under the recently extended regulations of the Special Grants Committee, allowing substantial grants extending over a considerable period in cases of serious illness of the wives, children, and dependants of serving soldiers, and the widows and orphans of soldiers deceased.

THE WAR.

TREATMENT OF WOUNDS IN WAR.

THE fourth Inter-Allied Surgical Conference, which met at the French Army Medical School, Val-de-Grâce, from March 11th to 16th, discussed reports upon a number of subjects, and arrived at a number of conclusions. The following is a translation, slightly condensed, of the first section. Translations of others will be published in subsequent issues.

I. TRANSFUSION OF BLOOD.

The results obtained by the transfusion of blood justify its being looked upon as the method of choice in the treatment of serious haemorrhages.

(a) *Early*.—The clinical condition of the wounded man affords the main indications for transfusion, and in the advanced posts must alone be depended upon, but additional information may be obtained from repeated observation of the blood pressure, and by red blood cell counts which are of value in wounds of the limbs. In circulatory collapse due to a very acute infection (gas gangrene) no favourable result has been observed after transfusion. The indications for transfusion in the treatment of shock have not yet been sufficiently defined.

(b) *Later*.—Corpuscular anaemia after haemorrhage is generally well borne, and does not justify transfusion if the general condition of the wounded man is satisfactory. On the other hand, secondary haemorrhage, diminution in the coagulability of the blood, failure of regeneration of the corpuscles, and chronic infections causing anaemia, may afford indications for transfusion.

Preliminary Precautions.

(a) *Risk of Transmission of Diseases*.—Donors should be examined and classified in order to avoid transmission of diseases such as syphilis or malaria.

(b) *Incompatibility of Corpuscles*.—Fatal results have been observed in cases in which the corpuscles of the donor were agglutinated by the plasma of the recipient. Such results are rare, and can be completely avoided by agglutination tests which can easily be extemporized. This being so, it is indispensable to examine the agglutination in all cases in which the circumstances render it possible, or to have the donors classified beforehand. At advanced posts it is justifiable to resort to transfusion, even if it be impossible to test the agglutination, as the risk of serious results is relatively small, but it should be tested in all other units.

(c) *Asepsis*.—Transfusion should never be undertaken unless an appliance in perfect condition is available and unless strict asepsis is possible.

Method.

The method of transfusion employed should make it possible to measure the quantity of blood transfused. The use of blood which has been preserved for several days has given satisfactory results, and has proved specially valuable in advanced posts during intense military activity. Indirect methods for the transfusion of fresh blood are more easy to employ than vascular anastomosis. The three indirect methods have all given good results—namely, the use of citrated blood, the aspiration of pure blood into an ampoule treated with paraffin, and its aspiration in a syringe. The general principle should be to practise transfusion as early as possible after the receipt of the wound, but it must not be employed until haemorrhage has stopped. In haemorrhage from thoracic or abdominal wounds, or wounds of the limbs, transfusion should be practised either before or during the operation, the time of transfusion depending on the condition of the wounded man.

(To be continued.)

THE EVACUATION OF MEDICAL UNITS IN THE SOMME REVERSE.

THE daily papers of April 22nd contained articles by their representatives at the war correspondents' head quarters in France, describing the withdrawal of the casualty clearing stations during the retirement which began on

March 21st. These descriptions resemble each other very closely, and confirm the accounts we were able to publish in the JOURNAL of April 6th and April 13th, but add topographical details which we were not then at liberty to mention. Before the German attack the forward clearing stations were arranged in two tiers or groups. The most advanced were situated at Ham, Cagny, and Noyon in the Fifth Army area, and at Tincourt, Ytres, Gréville, and Achiet-le-Grand in the Third Army area. The more advanced clearing stations of the Fifth Army felt the pressure first and were evacuated on March 21st. From Ham the patients were evacuated by road to Villers-Carbonnel, but shell fire forced a further move to Amiens, and thence again further back. The clearing stations at Noyon and Cagny were diverted southward to the neighbourhood of Compiègne within the French area. In the Third Army area the clearing stations at Tincourt and Ytres were threatened first, and were sent on the move, followed by that at Gréville. At Achiet-le-Grand a clearing station was shelled on March 21st, and during its retreat westwards was bombed by German airmen. The units withdrawn to Puchevillers also were bombed by night. Temporary shelter only was afforded to these units in the second line positions at Roze, Maricourt, Dernancourt, and Aveluy in the Ancre valley; thence they moved backwards, for the most part to their present positions. At Roze seventy patients remained behind with a medical officer and twelve orderlies, but were brought away at the last moment by some motor ambulances which chanced to be available; as the last ambulance left it came under rifle fire from the advancing Germans. It is stated that the huts in many instances were destroyed, and the tents either taken away or burned. A great deal of the lighter medical stores and appliances was saved, but a quantity of iron cots, bedding, and heavy disinfecting plant had to be abandoned to the enemy. The surgical instruments seem to have been saved; some were packed on wheeled stretchers, which were pushed along the roads at night by medical officers. According to war establishments every casualty clearing station is equipped for 200 patients; this minimum equipment can be stowed at a pinch in nine motor lorries. On opening up, however, every clearing station has always expanded its accommodation, sometimes seven or eight fold. It appears that the general principle in hurried evacuation has been to reverse this process, sending back first a complete unit of 200 beds, with staff and equipment, which opens up on a new site ahead of the remainder of the station. Thus by the time the later detachments arrive the nucleus of the clearing station is already at work. During the dismantlement of the forward stations the nursing sisters were sent away in motor ambulances or lorries; the casualties among them amounted to one killed and one wounded.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

LIEUT.-COLONEL H. STEWART, D.S.O., R.A.M.C.

Lieut.-Colonel Hugh Stewart, D.S.O., R.A.M.C., was killed in action on April 10th. He was born on April 15th, 1881, the elder son of the late Captain Hugh Stewart, of Hatley, Foxrock, County Dublin. He was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., and B.A.O. in 1904. Entering the R.A.M.C. as lieutenant on July 31st, 1905, he became captain on January 31st, 1909, major on October 15th, 1915, and acting lieutenant-colonel on February 1st, 1916. He received the D.S.O. on June 3rd, 1917.

CAPTAIN L. A. H. BULKELEY, R.A.M.C.

Captain Llewellyn Alfred Henry Bulkeley, R.A.M.C., is reported as having been killed in action on April 10th. He was the third son of the Rev. Canon H. J. Bulkeley of Coddington Rectory. He graduated M.B., B.S.Durh. in 1904, and, prior to settling in practice at Gateshead, had served as house-surgeon and house-physician to the Royal Infirmary, Newcastle-upon-Tyne, and house-surgeon to the Darlington Hospital and Dispensary. In 1915 he married a daughter of Dr. James Lawrence of Darlington. He

took a temporary commission in the R.A.M.C. about fifteen months ago, and was promoted to captain on completion of a year's service.

CAPTAIN A. L. GARDNER, R.A.M.C.

Captain Alfred Lintun Gardner, R.A.M.C., was killed in action on April 10th, aged 36. He was educated at Guy's Hospital, took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1912, and, after acting as assistant medical officer of the Poplar and Stepney Sick Asylum, went into practice at Ilfracombe. He took a temporary commission as lieutenant in the R.A.M.C. about two years ago, and was promoted to captain after a year's service.

Died of Wounds.

CAPTAIN J. CARMICHAEL, C.A.M.C.

John Carmichael, M.D., C.M. (Q.U.I. Kingston), Captain C.A.M.C., was born in March, 1889, at Collingwood, Ontario, and received his professional education at Queen's University, Kingston, Ontario, where he graduated in 1915. After acting as resident at the Western Hospital, Toronto, he joined the C.A.M.C. and preceeded to England in March, 1916. He had for two years been attached to the 35th Battalion Canadian Militia, and during his medical course had served as cadet instructor. After two months in England he proceeded to France, becoming attached to No. 2 and subsequently to No. 7 Canadian General Hospital. Later he went to the front as regimental medical officer, and there met his death from multiple wounds on April 5th.

CAPTAIN J. A. MACKENZIE, R.A.M.C.(S.R.).

Captain John A. Mackenzie, R.A.M.C.(S.R.), attached Durham Light Infantry, died of wounds on April 10th, aged 24 years. He was the elder and only surviving son of the late Mr. and Mrs. K. P. Mackenzie, Lechninver, Sutherlandshire. He was educated at Edinburgh University, where he graduated M.B., Ch.B. in 1916, and immediately took a Special Reserve commission.

TEMPORARY CAPTAIN D. MACKINNON, R.A.M.C.

Temporary Captain Duncan Mackinnon, R.A.M.C., died on April 12th of wounds received the same day. He was the youngest son of the late Professor Donald Mackinnon of Edinburgh University, and was educated at that university, where he graduated M.B. and Ch.B. in 1909.

Wounded.

Major R. F. Craig, Australian A.M.C.
Major C. B. Davies, M.C., R.A.M.C. (temporary).
Captain T. G. Allen, Australian A.M.C.
Captain A. Ball, R.A.M.C. (temporary).
Captain A. W. Berry, R.A.M.C. (temporary).
Captain T. F. Corkill, M.C., R.A.M.C.(S.R.).
Captain P. A. Creux, R.A.M.C. (temporary).
Captain E. Dempster, R.A.M.C.(S.R.).
Captain H. F. H. Eberts, R.A.M.C. (temporary).
Captain E. E. Isaac, M.C., R.A.M.C. (temporary).
Captain C. Jacobs, M.C., R.A.M.C.(T.F.).
Captain R. Kenefick, R.A.M.C. (temporary).
Captain P. McLachlan, M.C., R.A.M.C. (temporary).
Captain J. Manuel, M.C., R.A.M.C. (temporary).
Captain A. Merrin, R.A.M.C. (temporary).
Captain B. J. Mullin, M.C., R.A.M.C. (temporary).
Captain H. G. Pesel, R.A.M.C. (temporary).
Captain G. L. Pillans, M.C., R.A.M.C. (temporary).
Captain J. A. Tomb, R.A.M.C.(T.F.).
Captain A. U. Webster, R.A.M.C. (temporary).
Captain W. H. M. White, R.A.M.C.(T.F.).
Lieutenant G. N. Groves, R.A.M.C. (temporary).

Wounded and Missing.

Captain E. E. Mather, R.A.M.C. (temporary).

Missing.

Captain J. G. Anderson, R.A.M.C.(T.F.).
Captain J. B. Ball, R.A.M.C. (temporary).
Captain A. C. Bateman, M.C., R.A.M.C.(S.R.).
Captain A. J. Chillingworth, R.A.M.C. (temporary).
Captain S. J. Darke, M.C., R.A.M.C. (temporary).
Captain R. R. Duncan, R.A.M.C. (temporary).
Captain J. M. Eratt, R.A.M.C.
Captain H. B. Jones, R.A.M.C. (temporary).
Captain R. A. Leembruggen, R.A.M.C. (temporary).

Captain W. H. R. McCarter, R.A.M.C. (temporary).
Captain J. Tate, R.A.M.C. (temporary).
Captain J. P. Thierens, R.A.M.C. (temporary).

Prisoners of War.

Captain T. W. Leighton, R.A.M.C. (temporary).
Captain W. O'Brien, R.A.M.C. (temporary).
Captain D. M. Spring, R.A.M.C. (temporary).

Prisoner of War (formerly reported Missing).

Captain J. C. Muir, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Antill-Pockley, John G., Lieutenant Australian Imperial Force, son of Dr. Antill-Pockley of Sydney, killed March 30th.
Danne, A. W. Bryant, Lieutenant Gloucestershire Regiment, elder son of Dr. Danne of Bristol, killed March 30th.
Edmondson, I. E., Second Lieutenant Army Service Corps, son of Dr. H. Edmondson of Burnley, killed recently by a shell.

Gibbs, David Angus, Second Lieutenant Rifle Brigade, son of the late Dr. Cecil Gibbs, killed March 24th. He was educated at Winchester, got his commission in July, 1917, and went to the front the following month.

Grigson, Sydney Mark, Australian Flying Corps, younger son of Dr. R. C. Grigson of Sydney, died at Central Military Hospital, Aylesbury, April 17th, aged 20.

Smith, J. Noble, Second Lieutenant, youngest son of the late Dr. Noble Smith of Worthing, killed April 9th, aged 19.

Stalker, Daniel, Lieutenant Royal Field Artillery, eldest son of Professor A. M. Stalker of Dundee, died of wounds, April 12th, aged 27. He was educated at Dundee High School, and at Edinburgh University, where he graduated M.A., and became lieutenant on March 19th, 1915.

MEDICAL STUDENT.

Vassie, Richard, Lieutenant Cheshire Regiment, only son of James Arthur Vassie, died at Lanark on April 13th, of illness contracted on active service in France, aged 23. He was educated at Fettes College and at Edinburgh University, where he was a third year medical student at the beginning of the war, when he enlisted in the Scottish Horse. He got his commission in September, 1914, became lieutenant on January 14th, 1915, went to the front in September, 1915, and was invalided a month later.

News has been received by Dr. E. W. Martland that his son, Lieutenant E. N. P. Martland, R.A.M.C., reported missing in last week's JOURNAL, is a prisoner in Germany, and in good health.

In announcing last week the death of Lieutenant Edward J. Gray among the deaths of sons of medical men, it was accidentally assumed that his father, Dr. Alan Gray of Cambridge, was a medical man; Dr. Gray is a doctor of music and the distinguished organist of Trinity College.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

THE following medical officers are included in a further list of recipients of the Military Cross, in recognition of conspicuous gallantry and devotion to duty, published in a special Supplement to the *London Gazette* of April 22nd.

TEMPORARY CAPTAIN CECIL FRANCIS DILLON-KELLY, R.A.M.C.

Establishing his regimental aid post in the captured enemy line, he himself kept in touch with the advanced troops, and dressed the wounded under heavy machine-gun and rifle fire. He remained in the most advanced positions, dressing the wounded until every case had been evacuated, and showed an excellent example of disregard of danger and courageous determination.

CAPTAIN ARTHUR JOSEPH GORDON HUNTER, R.A.M.C.

His battalion being engaged on both sides of the river at points a considerable distance apart, he repeatedly went out in the face of heavy machine-gun and rifle fire to organize the collection and evacuation of the wounded. His gallant behaviour and magnificent coolness inspired the men working under him with the utmost confidence.

CAPTAIN LOUIS LAURENCE MCKEEVER, R.A.M.C.

During an engagement, hearing that there was no medical officer in the front line, he at once went forward under an intense bombardment and remained in the front line all night attending to the wounded under continuous and violent shell fire. He set a splendid example of courage and devotion to duty.

A special SUPPLEMENT to the *London Gazette*, dated April 23rd, contains the following records of conspicuous gallantry and devotion to duty for which the decorations announced in the *Gazette* (BRITISH MEDICAL JOURNAL, December 22nd, 1917, p. 839) were conferred:

Bar to the Distinguished Service Order.

Temporary Captain (temporary Lieut.-Colonel) Charles Derwent Pye-Smith, D.S.O., M.C., R.A.M.C.

He was in command of the three field ambulances of the division during ten days' operations. The weather conditions were

abnormal's bad and a large number of the wounded of another division had not been evacuated. Owing to his constant presence and influence all the wounded were got away promptly and without assistance from the infantry.

Distinguished Service Order.

Captain William Henry Collins, A.A.M.C.

Finding that his regimental stretcher-bearers were unable to find a regimental aid post which he had established in a German "pill-box," he personally led the first party of them through an intense artillery and machine-gun fire barrage. Although knocked down by a bursting shell, he immediately resumed the dressing of the wounded. Although, owing to casualties, he had only two men to help him, he courageously persevered with his work and himself helped to excavate a dug-out for the wounded under heavy shell fire, during which several of the wounded were killed. He remained on duty for sixty hours and refused to leave his post till the last wounded man had been evacuated. By his constant cheerfulness under the most adverse conditions, and by his utter disregard for his own safety, he kept up the spirits of the wounded and stimulated his surviving helpers to their utmost effort.

Major Eric Lloyd Hutchinson, A.A.M.C.

When in charge of the evacuation of wounded from the forward area he led a relief of stretcher-bearers along a track knee-deep in mud, and at times over his waist in water. Another time he led a party through an intense barrage, thus relieving a temporary congestion of the wounded. He had very little rest during the whole four days.

Temporary Captain William Howard Lister, M.C., R.A.M.C.

As bearer officer he took parties to the regimental aid posts, though they suffered heavy casualties on the way. When a regimental medical officer was wounded, he attended to the wounded of this battalion, searching our lines and "No Man's Land" from midday to dark for wounded, and then returned to his field ambulance for another twelve hours' work until relieved.

Major Philip Alan Maplestone, A.A.M.C.

When in charge of all stretcher-bearers and forward posts he showed the utmost coolness under very heavy fire, during which several shelters were hit. By his example he prevented any panic and prevented serious casualties from gas shells. Although gassed himself, he remained on duty till the forenoon of the following day, having been on duty for over thirty hours. Even then he refused to be treated as a casualty, but after a short rest he returned to the advanced dressing station and carried on his duties.

Bar to the Military Cross.

Captain Richard Thompson Caesar, M.C., R.A.M.C.

In evacuating the wounded under very heavy and continuous fire he systematically searched the battlefield from shell hole to shell hole for wounded, until he could report that all casualties had been removed.

Temporary Captain John Maitland Forsyth, M.C., R.A.M.C.

He went up to the front line several times to search for and tend the wounded under heavy shelling and sniping. It was owing to his tireless energy that the casualties, which were very heavy, were so well evacuated. His aid post was twice hit by shells, once causing nine casualties to his bearers.

Captain Cyril Jacobs, M.C., R.A.M.C. (S.R.).

His dressing station, formed under heavy fire, was once blown in on top of him and five casualties occurred, but he remained at his post and managed to evacuate all wounded. On the following day he cleared the battlefield in spite of heavy fire, and brought back twenty badly wounded cases.

Temporary Captain David Henry Russell, M.C., R.A.M.C.

He successfully evacuated a large number of wounded under constant shelling and in very bad weather conditions. He frequently helped to carry wounded, although himself exhausted.

Temporary Captain Philip Randal Woodhouse, M.C., R.A.M.C.

When the battalion was formed up in the assembly area all the battalion medical staff except himself were wounded. He carried the medical haversacks all day and tended the wounded under fire. He was slightly wounded, but continued to work single-handed for two days.

(To be continued.)

FOREIGN DECORATIONS.

The following decorations have been awarded by the President of the French Republic for distinguished services rendered during the course of the campaign:

Légion d'Honneur.—Croix d'Officier: Colonel (temporary Major-General) G. L. Foster, C.B., D.M.S., Canadian Forces. Croix de Chevalier: Colonel G. E. Beauchamp, C.A.M.C.

Croix de Guerre.—Colonel T. Du B. White, C.M.G., A.M.S., Captains J. F. Edmiston, R.A.M.C., J. H. P. Fraser, R.A.M.C., S. R. Gibbs, R.A.M.C. Temporary Captains E. G. Stanley, R.A.M.C., G. T. Cregan, M.C., R.A.M.C. Temporary Lieutenant R. J. Helsby, R.A.M.C.

The King has conferred the Distinguished Service Cross upon Surgeon (acting Staff Surgeon) A. G. Vavasour Elder, R.N.V.R., in recognition of his services in connexion with naval ambulance trains and sea hospital transport throughout the war. Acting Staff Surgeon Elder was frequently under fire at the Gallipoli beaches.

Major Kenneth MacCormick, of the N.Z.M.O., who received the D.S.O. for the services published in the *London Gazette* of April 6th, 1918 (BRITISH MEDICAL JOURNAL, April 13th, p. 440), was incorrectly described as belonging to the C.A.M.C.

NOTES.

TETANUS FOLLOWING INTRAMUSCULAR INJECTION OF QUININE.

The following report records a sequence of events which has, we believe, very rarely been observed:

Pte. B., aged 24, who was suffering from malaria contracted in Macedonia, received an intramuscular injection of quinine on March 8th, 1918. On March 19th he complained of stiff jaws, and later on of stiff neck. A subcutaneous injection of 8,000 units of antitetanic serum was given. On the morning of March 20th he had frequent tetanic spasms. At 10 a.m. on that day he received 8,000 units of antitetanic serum intramuscularly and 16,000 units intrathecally, followed by 16,000 units intravenously. He died from generalized tetanus at 5.30 p.m. on the same day.

A post-mortem examination was made. A saline emulsion of the muscle from the site of the quinine injection failed to induce tetanus in a guinea-pig inoculated with it, but a second guinea-pig, inoculated with a muscle extract of the first animal, developed true tetanus within twenty-four hours. The bacteriologist recovered the tetanus bacillus from the muscles at the site of inoculation in both guinea-pigs, while from the muscle of the patient only a few bacilli were cultivated which morphologically resembled the tetanus bacillus.

CEREBRO-SPINAL FEVER IN THE FRENCH ARMY.

In a paper read recently before the Académie de Médecine, Dopter (*Bull.*, lxxxix, 169-171), who a few months ago published an admirable book on the diagnosis and treatment of cerebro-spinal fever (reviewed on February 23rd, p. 233), gives an encouraging account of the recent incidence of the disease in the French army, and ascribes the improved record to fresh air and the absence of overcrowding. During 1915 there were 1,073 cases, or 4.2 per 10,000; 451 cases, or 1.8 per 10,000, during 1916; and 409, or 1.5 per 10,000, during 1917. He draws attention to a curious change in the bacteriological etiology of the disease during the war; in 1915 the great majority of the cases were due to the meningococcus, type A (Nicolle), but during 1916 the parameingococcus or meningococcus B and C (Nicolle), which before the war was rare, became prominent. The disease becomes more evident towards the end of December, reaches its maximum in March, diminishes to its lowest activity in the autumn, but contrary to its behaviour in pre-war times persists during the summer. The general aspect of the disease is that of an endemic affection with small foci of six to eight cases. During cold weather exacerbations coincide with sudden falls in the temperature, and recruits shortly after their arrival at instructional centres are the most subject, as a result of exposure to cold and fatigue on the journey.

Scotland.

THE OUTLOOK ON TUBERCULOSIS.

SIR ROBERT PHILIP gave his inaugural address as professor of tuberculosis in the University of Edinburgh, in the McEwan Hall, on April 16th. In some introductory remarks the principal, Sir Alfred Ewing, said that the University owed the establishment of the new professorship to the Royal Victoria Hospital Tuberculosis Trust. There was no other chair of tuberculosis in the world, and it was eminently fitting that the first should be founded in Edinburgh, as the system of dealing with that fell disease was being copied as the Edinburgh system all over the world. It was satisfactory that the chair was occupied by the man who had created that great organization.

Sir Robert Philip said that the ravages of tuberculosis, though still appalling, had been greatly reduced. From the Registrar-General's figures for 1915 it appeared that in England 54,295 persons died of tuberculosis, representing a death-rate from all forms of 151 per 100,000. In Scotland 7,819 died of tuberculosis, a rate of 165 per 100,000. From pulmonary tuberculosis alone, in England there died 41,676 persons, a death-rate of 116 per 100,000, and in Scotland 5,291 persons, a death-rate of 111 per 100,000. Comparable figures for England twenty-five years ago showed a death-rate of 168 per 100,000, representing a fall of 30.9. In Scotland the death-rate was then 193 per 100,000, so that the fall was 42.4 per cent. This fall was not due to natural causes which had influence in all civilized countries. In 1915 the figures per 100,000 of the population were: Scotland 111, England 116, Germany 142, Ireland 172, France 179. Such facts afforded a striking commentary on the view of Metchnikoff and others that a process of gradual immunization was in progress in thickly populated countries. The fascinating theory of communal immunization on natural lines failed when

tested by facts. The problem of tuberculosis was urgent, and the place occupied by tuberculosis in medicine was large. A return prepared by the registrar of the Edinburgh Royal Infirmary showed that during the year ending January 31st, 1918, some 650 cases, including tuberculosis of practically every organ and structure of the body, were treated within the wards. The list did not include out-patients, and the numbers were the more remarkable inasmuch as the Royal Infirmary was a general hospital, which in principle excluded infective conditions. He considered the prospect for the future full of hope. No disease was more tractable if its character were recognized sufficiently early. Nature cured tuberculosis every day. The treatment of tuberculosis had been revolutionized by the recognition of the principle of aërotherapy, and by fulfilment of physiological demands for rest, movement, and feeding. In the adaptation of aërotherapy to the prevention and treatment of disease there existed the potential of successes comparable with those obtained in surgery through the practice of aseptic methods. After discussing the possibilities of vaccine-therapy and chemotherapy, the lecturer spoke of the prevention of the disease. The war had only made more evident the urgent need for a wisely directed comprehensive campaign against tuberculosis. There were indications in some parts of the country of an increase in the death-rate from tuberculosis; the conflict was with an aggressive infection having immense ramifications, whose ravages could be checked only by unremitting effort on approved lines. One encouraging fact was that the British armies had suffered less than those of continental powers. In conclusion, he spoke of the need for training in the prevention and treatment of tuberculosis.

THE PHYSICAL WELFARE OF MOTHERS AND CHILDREN.

The reports issued by the Carnegie United Kingdom Trustees on the existing provisions for promoting the physical welfare of mothers and young children in England and Wales and in Ireland have already been reviewed in the columns of the JOURNAL. A third volume deals with Scotland.¹ The introduction by the Secretary of the Carnegie Trust emphasizes the importance of this work of collective investigation and report, because the rate of infantile mortality and its predominant causes, as well as the health supervision of children from infancy to the age of admission to school, are among the most important problems of the present day.

In preparing this report and survey of medical, statistical, social, and administrative materials, Dr. W. Leslie Mackenzie has tried to preserve freshness of outlook on the facts. Investigators visited the places under review, made notes of their inspections, interviewed officials, obtained from them directly such relevant printed or written matter as was readily available, and received verbally much valuable direction in a very complicated inquiry. By these means first-hand records were made of living experience—much that rarely finds its way into print. The effect has been to produce a book brimful of the most absorbing human interest and a record of the highest value to social workers of whatever grade.

One of the most interesting features of the report is that dealing with the distribution of the population. For the most part the people congregate along certain valley and coast lines and are but thinly scattered over the mountainous regions. In some of these valleys great cities have sprung up within recent years owing to the expansion of certain industries. There are steel cities and coal cities. The problems of life in these regions of widely different character require separate treatment. Even in the towns there are differences; the older towns or burghs have an established life of their own, very different from the life in the vast new industrial areas with their special problems of massed humanity. The report deals very illuminatingly with these different conditions and the special means adopted to meet their problems. Then there are parts of the land, in the highlands and islands, where life is at an almost primitive level, where are to be seen dwellings but little removed from prehistoric huts; the excellent photographs reproduced in the book would

suggest some distant clime were it not for the clothing of the people about the places. The diversity of the problems connected with maternity under such varying conditions may be illustrated by two examples. Writing from Dundee Miss Mary Paterson says:

As a result of my inquiry I feel convinced that mothers and children would both benefit if the period of absence from the mill after childbirth were extended. An amendment of the Act making a three months' absence compulsory now, the period of absence to be extended further at a future date, would give the child a chance which it does not seem to have now, and would no doubt result in the more general (and more wise system of) nursing by the mothers. Many women have to leave the mill some time before childbirth because their work fails to come up to the required standard, and this is often a blessing to them, little though they realize it. Compulsory absence would, I am assured, lessen the sufferings of the women and reduce the number of stillbirths, but the difficulty of enforcing the law would, of course, be great, and the responsibility necessarily rest on the woman herself.

Amongst the special studies recorded is a report of life in a Shetland island:

There a woman usually goes about her ordinary work up to the time of her confinement. At the first sign of labour coming on the midwife is sent for post haste. The patient goes to bed and remains there till, at the earliest, the "ninth day." Formerly it used to be thought dangerous to wash the patient at all after childbirth, any old pieces of cloth were thought to be good enough to use for absorbing discharges, and I often wonder how the poor women ever got well again. Up till quite recently the poor woman was practically starved for four or five days, but now a more common-sense view is taken and proper nourishment allowed. The infant spends most of the first two years of its life in a cradle, generally made of wood, with a wooden hood absolutely wind-proof. There is seldom any regularity observed in feeding; a cry is a sign that the child wants food, and, in consequence, the child is constantly over-flowing. Old wives still have great influence in these undiscovered territories.

Correspondence.

BOTULISM.

SIR,—Professor Arthur J. Hall's letter on botulism in the JOURNAL of April 20th (p. 467) is of special interest at the present time. The clinical picture presented by the Sheffield cases appears closely to resemble that of the classic accounts given of this very rare disease. Assuming that they are cases of true botulism and due to the ingestion of specifically infected food, it is of the first importance that the food at fault should be identified either by discovering the *B. botulinus* in portions of some of the material actually eaten by the patient, or by the method familiar to epidemiologists of finding in a detailed and exhaustive food history of a group of cases some food material which is not only common to, but in a certain degree peculiar to, them all.

In order that one or other of these methods of investigation may be applied at the earliest moment, while there is still a chance of obtaining a portion remaining over from any suspected food eaten, and while the memory of the patient or his friends is still fresh as to the foods recently consumed, it would be desirable for medical practitioners to communicate at once with the medical officer of health of their district when any suspicious case comes under their observation.

I shall be glad if medical officers of health who may have had such cases brought to their notice will send me as full particulars, especially as regards food history, as they can obtain. I will arrange to have examined for them any samples of food materials which they may have good reason to suspect of having given rise to this illness.—I am, etc.,

Local Government Board,
Whitehall, S.W.1.

A. W. J. MACFADDEN.

THE VALUE OF THE WASSERMANN TEST.

SIR,—The memorandum by Dr. J. S. Robertson in your issue of April 13th, p. 427, is a typical example of a little knowledge being dangerous. He states that "the Wassermann test carried out in the usual way is useless," and in support of this far-reaching assertion what is his evidence? First, that in a pregnant woman with obvious syphilis the test was negative. Even the most inexperienced should know that this is the usual result, but

¹ *Scottish Mothers and Children. Being Report on the Physical Welfare of Mothers and Children, Scotland.* By W. Leslie Mackenzie. Medical Member of the Local Government Board for Scotland. The Carnegie United Kingdom Trust, East Port, Dunfermline. 1917. (8vo, pp. xxvii + 632.)

that after labour the test may be positive, and no pathologist would attach any importance to a negative test obtained during pregnancy. Second, that patients with obvious syphilis were declared to have a negative Wassermann, or that different results were obtained from the same case in different institutions, or even by the same worker. The obvious reply to this is either that the diagnosis was wrong—and even clinicians may err—that the blood was sent at an unsuitable time—for example, during treatment—or that the methods in doing the test were not properly carried out. As to the question of diagnosis, one has known clinicians of even lock hospitals to be wrong about "obvious syphilis," and, if the pathologist were as unscientific as the writer of the memorandum, he might say "my Wassermann tests show how fallacious is the diagnosis of syphilis by Dr. Robertson," or even the well-known surgeon to whom he refers.

The pathologist, however, does not assert this, because as one trained in scientific scepticism he looks at all the evidence, and is not prepared to say that a negative Wassermann test is absolute proof of the absence of syphilis; and further, he knows only too well that a test of this kind must be carried out with the greatest care and with all reagents properly standardized, and that the results must be interpreted by experienced workers. That these conditions are not always, or one might say even generally, fulfilled is also an obvious fact. When a test is being made in a chemical laboratory, the solutions used are standardized, all measurements are made with the greatest accuracy, and if the result is not what was expected, the worker generally asks, "Where did I go wrong?" but with the Wassermann reaction—a chemical test—the standardization of reagents and accurate measurements are too often ignored, and when the result turns out to be different from that expected then we are told, not that the work done but that the test itself is useless.

As I have said, I am not prepared to say that the test is infallible in the diagnosis of syphilis, but I am sure I voice the opinion of most experienced workers when I say that it is of extreme value in diagnosis, and in estimating the result of treatment, if it is carried out properly and with due consideration of the time after treatment at which the test is made, etc. Personally I feel that no case should be declared free with less than two negative reactions—one, one month, and the second three months after the cessation of all forms of treatment. Too often I have seen cases declared cured after a course of treatment, either without a test or with a negative result a few days after the last injection, with the result that a valuable aid to diagnosis—for I regard the test as an aid to, and not a substitute for, clinical diagnosis—is regarded as useless.—I am, etc.,

J. M. BEATTIE, M.D.,

University of Liverpool,
April 23rd.

Professor of Bacteriology.

ACUTE YELLOW ATROPHY IN SYPHILIS.

SIR,—In regard to Dr. Nathan Raw's memorandum in the JOURNAL of April 20th, p. 454, I should like to point out that acute yellow atrophy of the liver ("acute atrophy" or "subacute atrophy" are preferable terms) was well known as an occasional complication of syphilis before the days of the arsenical treatment by salvarsan, etc. In the *Proceedings of the Royal Society of Medicine for 1909* (Pathological Section, vol. ii, pp. 113-122) I described such a case, and endeavoured to give a summary of the already at that time very considerable literature on the subject. The acute hepatic atrophy seems in most cases to have occurred during the late primary or early secondary stages, like acute syphilitic meningo-encephalo-myelitis. Since the introduction of treatment by salvarsan, etc., both precocious syphilis of the nervous system and precocious hepatic symptoms have frequently been ascribed to the action of the arsenical treatment. The probability appears to be that in exceptional individuals the treatment in question does really favour the onset of such serious, and often fatal, complications.—I am, etc.,

London, W., April 20th.

F. PARKES WEBER, M.D.

DEFECTIVE UTILIZATION OF MEDICAL MEN IN HOME COMMANDS.

SIR,—In your comments upon the position of the medical profession under the new Act you express a doubt whether

the available material is always utilized to the best advantage. May I call attention to one direction in which this doubt seems justified?

Surgeons and physicians still engaged in active practice are employed to visit and inspect hospitals in the various commands. Their names carry prestige, but it is manifest that in occasional short inspections questions of actual practice cannot be dealt with, and all that the inspection can effect is to see that accommodation and general administration are satisfactory or otherwise. This could be quite as efficiently done by medical men whose time of usefulness in a purely medical capacity has gone by, but who have devoted some of their years of leisure to hospital administration. There are many such who would gladly undertake this work.—I am, etc.,

April 22nd.

F.R.C.S.

FUNCTIONAL HEART DISEASE AND RECRUITING.

SIR,—As a member of a medical board I have been much impressed with the large number of young men brought up for examination who exhibit a very definite form of functional heart disease, for which in some instances they have previously been "deferred." These youths exhibit a syndrome of three well-marked signs which I have observed for some twenty years or more to be invariably associated with a certain vicious habit. I have seen scores of such cases, and have never once been mistaken in the diagnosis since first learning to recognize the three signs. Sometimes the youth, when first accused, denies the practice; but when the examiner says to him, "I am not asking you, I am telling you; do you practise it now?" he almost invariably acknowledges it, but adds that he gave it up some weeks or months ago. The habit referred to is masturbation. The following signs constitute the syndrome:

1. Widely dilated pupils. This sign in a young man who is not suffering from marked anaemia should at once raise in the mind of the examiner the suspicion of masturbation as the cause.

2. The examiner then places his hand over the heart to feel the apex beat. In these cases the beat is felt to be markedly accentuated, giving the impression of a thin-walled ventricle. The beat is short and sharp, and in the normal position.

3. The pulse, which one might expect from the character of the heart's action to be full and fairly strong, is small and very compressible. Its rate is little, if any, beyond the normal.

The contention is that large pupils, marked accentuation of the cardiac impulse, and a small compressible pulse, form a syndrome which is the result of the above-mentioned vicious habit, and which, when seen in the same individual, are pathognomonic of the condition.

The hints given in textbooks as to the indications of this habit are, in my experience, quite unreliable, and a recent article on masturbation in a leading medical periodical is also, from the point of view of diagnosis, absolutely valueless.

As regards the "grading" of these men, there is no necessity to "defer" them, or to place them in a low category, if they are otherwise quite sound; indeed, the graduated training will be so beneficial that I never hesitate to place them in Grade L.—I am, etc.,

Wrexham, April 22nd.

H. DRINKWATER.

THE National Health Society, which during the forty years of its existence has done much excellent work, especially in instructing women in hygiene and preparing some of them to hold public appointments under local authorities, is making an appeal for £5,000 to provide small bursaries for suitable candidates during their period of training. Full particulars of the objects of the fund and of the courses arranged for women desirous of becoming sanitary inspectors, health visitors, superintendents of infant welfare centres, and factory inspectors, can be obtained from the secretary, Miss Lankester, 53, Berners Street, London, W.1. The appointments of sanitary inspector (Kensington and Lewisham), superintendent of infant welfare centre (Lambeth), and health visitor (Blackburn) have recently been obtained by students of the society.

Obituary.

C. F. M. ALTHORP, M.B.LOND.,

Senior Surgeon to the Bradford Royal Infirmary.

WE regret to announce the death of Dr. Charles Frederick M. Althorp of Bradford, which took place at his residence on April 8th. Dr. Althorp was a native of Bradford and was educated at the Grammar School and at the Leeds School of Medicine. He took M.R.C.S. and L.R.C.P. diplomas in 1887 and the M.B.Lond. degree in 1891. After qualifying, he held resident posts at the Leeds General Infirmary and the Bradford Royal Infirmary. At the latter he remained two and a half years, resigning his post to be appointed one of the first assistant surgeons to that institution. He became full surgeon in 1898, remaining in office until a short time before his death, when he tendered his resignation on account of ill health. When the St. Luke's (Bradford) War Hospital was established Dr. Althorp accepted an appointment as one of the visiting surgeons, continuing to act until a few weeks ago. His work for the war also included the medical officership of the "Bradford Pals" Battalion, the 16th and 18th W. Yorks, during their training in Bradford. Dr. Althorp was a consistent supporter of the British Medical Association, and for some years occupied a seat upon the Ethical Committee of the Bradford Division. His chief interest, however, lay in the affairs of the Bradford Medico-Chirurgical Society, and he was a regular contributor to its proceedings of papers of great surgical interest, as well as being a frequent participant in the scientific discussions. He served the society for some years as an energetic and enthusiastic secretary; was president in the session 1904-5, and long acted as honorary librarian.

In 1916 a serious breakdown in health laid him aside for nine months, but he returned pluckily to work, and his last visit to the War Hospital was the last occasion upon which he left his house. His death is mourned by hosts of friends in the profession and amongst his hospital and private patients. Modest and retiring to a fault, he was a generous colleague, a loyal friend, and a sound surgeon.

GEORGE ROWELL, F.R.C.S.Eng.,

Anaesthetist, Guy's Hospital.

WE regret to record the death of Mr. George Rowell, senior anaesthetist to Guy's Hospital and president of the Section of Anaesthetics of the Royal Society of Medicine. Mr. Rowell received his medical education at Guy's Hospital, and obtained the M.R.C.S. and L.R.C.P. in 1886, and the F.R.C.S. two years later. His former appointments included those of anaesthetist to the Royal Dental Hospital, the West End Hospital for Nervous Diseases, and the Royal Orthopaedic Hospital, and since the war he had served as honorary anaesthetist to the King George Hospital and to the Royal Flying Corps Hospital. In 1891 the Council of the British Medical Association appointed a special committee to investigate the clinical evidence with regard to the effects of anaesthetics upon the human subject, and especially the relative safety of the various anaesthetics, the best methods of administering them, and the best methods of restoring a patient in case of threatened death, and Mr. Rowell was appointed honorary assistant secretary. Ten years later he was member of the Special Chloroform Committee appointed by the Council of the Association to investigate methods of quantitatively determining the presence of chloroform in the air and in the living body. In addition to his work on these committees, Mr. Rowell contributed a number of practical papers on anaesthesia to medical periodicals.

We are indebted to Sir W. ARBUTHNOT LANE for the following appreciation:

George Rowell, who died on April 17th at the age of 54, occupied for many years a very prominent and respected position in the anaesthetic world. He held many appointments, the chief being that of senior anaesthetist and lecturer on anaesthetics at Guy's Hospital. He was an excellent teacher, and was most popular with the students; the care and attention which he gave to their instruction have proved most useful to them in practice. As an anaesthetist he was perfect. He inspired his patient with absolute confidence, while the surgeon knew that he could rely

implicitly on his skill and judgement, which, within the recollection of his friends, were never known to fail in a single instance. He was one of the first to recognize the value of open ether, which he advocated very strongly when he held the post of joint secretary to the British Medical Association's commission on chloroform anaesthesia. Since the commencement of the war he has given his services freely to several voluntary hospitals, and it is largely due to the excessive strain which this additional work entailed that his vitality was so lowered as to render him unable to withstand the infection from which he died, and which he may well have acquired in the performance of his professional duties. He was one of the most warm-hearted, generous, and loyal men one could ever meet, and the name and recollection of George Rowell will always occupy a very warm and cherished spot in the hearts and memories of a much larger circle of friends than it is given to most men to enjoy. Their devotion to him was truly remarkable, and it will ever be a matter of regret to them that he did not better employ his exceptional abilities to his own personal advancement. He leaves behind a most loyal and devoted wife and son, to whom his loss is irreparable.

DR. EDWARD THOMAS WILSON, for many years one of the leading physicians of Cheltenham, died on April 19th, at the age of 85. He studied medicine in the University of Oxford, where he gained first class honours in natural science, and at St. George's Hospital. He obtained the M.B. degree in 1858, and became M.R.C.P. in 1860 and F.R.C.P. in 1870. His connexion with the Cheltenham General Hospital, which he served as physician for thirty-one years, began with his appointment to the medical staff of the branch dispensary nearly sixty years ago. He was also for many years medical officer to Cheltenham College, to the Cheltenham Ladies' College and Dean Close School, and consulting physician to Winchmore Cottage Hospital and the Cotswolds Convalescent Home. At the annual meeting of the British Medical Association at Nottingham in 1892 he was vice-president of the Section of Public Medicine; and nine years later, when the annual meeting was held at Cheltenham, he was president of the Section of Medicine. Dr. Wilson published a number of papers on infectious disease, and was the author of Sanitary Statistics of Cheltenham, of which the first series was published in 1865, and the second in 1872. In former days he was a keen microscopist, and served as president of the Cheltenham Natural Science Society. He was a brother of Major-General Sir Charles Wilson, who went up the Nile to open up communication with Gordon at Khartoum; and one of his sons was the late Dr. Edward Adrian Wilson (head of the scientific staff of the national Antarctic expedition, 1910), who perished heroically with Captain Scott on the return journey from the South Pole.

DR. M. PROSSER JAMES, who died recently at his residence in North Kensington, aged 82, was in former years well-known in laryngological circles. He received his medical education at the London Hospital, and took the diplomas of M.R.C.S. in 1856, L.S.A. in 1857, and M.R.C.P. in 1867. He graduated M.D. St. Andrews in 1857. He was consulting physician to the Children's Home Infirmary, Victoria Park, and had been physician to the Hospital for Diseases of the Throat, Golden Square, and to the North London Consumption Hospital, and lectured on forensic medicine and therapeutics at the London Hospital. He was a corresponding member of the Academies of Medicine of Madrid and Lyons, and was the author of several books on diseases of the throat and nose, and also on climatology and therapeutic mineral waters. He was one of the founders, in 1887, of the British Laryngological and Rhinological Society, and was one of the earliest workers with the laryngoscope and rhinoscope. For many years Dr. Prosser James took a deep interest in the affairs of the Western Skin Hospital, of which he was honorary treasurer, and he was a strong supporter of the Hamilton Association for trained male nurses. In 1875 he had a severe attack of rheumatic fever, and for the remainder of his life was unable to walk. Throughout this invalid existence he found solace in his library, where he indulged his strong literary taste and love of reading.

THE death, on April 8th, of Dr. ROBERT STEVENSON of Bootle, came as a shock to many of his friends. He died after a few days' illness, from acute pneumonia, at the age of 56. He was born in Scotland, graduated M.B., C.M. Glas. in 1837, and became M.D. in 1897. He had been in practice at Bootle for over twenty years; he became a member of the Liverpool Medical Institution in 1901, and was an active member of the Council in 1917. Dr. Stevenson held many public appointments, and was honorary anaesthetist to the David Lewis Northern Hospital, Liverpool. He was held in high regard by his fellow townsmen; to a native shrewdness he added painstaking skill, and was in consequence a busy practitioner. Of a somewhat retiring disposition, he took no prominent part in public affairs, but secured the esteem of his professional brethren and a large circle of friends. The funeral took place on April 11th at Bootle Cemetery. A large number of friends and representatives of the institutions to which he acted as medical officer were present to testify to the sterling merit of Dr. Stevenson. He leaves a widow to mourn his loss, and many Bootle residents to cherish his memory.

We regret to announce the sudden death, on March 24th, of Dr. H. ALDERSMITH, formerly medical officer to Christ's Hospital, first of all when it was still in the City of London, and afterwards when it was removed to Horsham. Dr. Aldersmith studied medicine at St. Bartholomew's Hospital, obtained the M.R.C.S. diploma in 1870, and the fellowship two years later, and graduated M.B. Lond. in 1875, obtaining the university scholarship and gold medal. He also won the gold medal of the Apothecaries' Society, and a senior scholarship at St. Bartholomew's Hospital, where he held the appointments of house-surgeon and house-physician. Dr. Aldersmith was the author of a small work on ringworm and alopecia, which reached its fourth edition in 1897. He took a deep interest in the welfare of the Horsham Cottage Hospital, of which he was honorary secretary.

DR. VERNON HAROLD STARR, Church Missionary Society, was stabbed by a fanatic at Peshawar on March 17th, and died twelve hours later, aged 35. He was the son of the late Mr. H. P. Starr, and was educated at King's College Hospital, London, graduating M.B. and B.S. Lond. in 1908. After acting first as assistant and then as senior house-surgeon of the Royal Devon and Exeter Hospital, he went to Peshawar in 1910 as surgeon in charge of the Church Missionary Society's mission hospital in that city.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved in both parts of the examination in Sanitary Science: D. W. Beswell, Edna M. Goffe,* J. L. Gregory, May I. T. Reid, A. J. H. Russell,* Jane Stalker, E. J. Tyrrell.

* Distinguished in bacteriology.

Medical News.

THE late Sir James Alexander Russell, M.D., of Edinburgh, left £33,766 gross.

SURGEON-GENERAL SIR ARTHUR W. MAY, R.N., K.C.B., has been appointed a deputy lieutenant of the county of Cornwall.

DR. EDWARD BUXTON, M.D., F.R.C.S.E., J.P., has been unanimously elected chairman of the Great Crosby Urban District Council for the ensuing year.

DR. SIDNEY MATTHEWS (Crawley) has been added to the Commission of the Peace for Sussex.

DR. DONALD MURRAY, M.O.H. for Stornoway, has been adopted as the prospective candidate for the representation in Parliament of the Western Isles.

AT a meeting of the Central Midwives Board on April 18th Sir Francis Champneys was unanimously re-elected chairman. Fifteen midwives were removed from the roll on their own application.

A PROCLAMATION has been issued under the new Military Service Act cancelling as from April 24th all exemptions granted by tribunals or Government departments to men between 19 and 23 in grades 1 and 2, or categories A, B 1, B 2, and C 1, with certain exceptions, which include duly qualified medical practitioners.

DR. J. M. H. MACLEOD will give a course of demonstrations on skin diseases, especially those met with in military wards, at Charing Cross Hospital on Tuesdays, at 3 p.m., commencing on Tuesday, May 7th. The demonstrations are open to all medical practitioners and medical students.

A SERIES of lectures and demonstrations on the feeding and care of infants will be given by Dr. Truby King, C.M.G., in the Governors' Hall, St. Thomas's Hospital, on Tuesdays and Fridays. Sir Arthur Stanley will take the chair at the first lecture at 5.30 p.m. on Friday, May 3rd. Members of the medical profession, nurses, and infant welfare workers can obtain tickets from the secretary of the hospital.

DR. CHAUVÉAU, representative of the Côte-d'Or, has been elected chairman of the French parliamentary group by thirty-one out of thirty-four votes. In thanking the members for the honour done him, Dr. Chauveau pleaded for a closer union between the group and the medical press and professional associations so that parliament might be kept in touch with the profession.

COLUMBIA UNIVERSITY has received £10,000 from an association of medical women, and contributions from other donors amounting to £3,600, to enable it to begin the erection of buildings in the medical department for the accommodation of women students. The university has lately received a gift of £600 from an anonymous donor for research in war problems, and another of £1,000 from Mr. Clarence Mackay for surgical research work.

A MEETING of medical men, jurists, and philanthropists representing every part of Switzerland has been held to discuss the formation of a Swiss association for the prevention of venereal disease. Professor Bloch, director of the dermatological clinic of the University of Zürich, and Colonel Hauser, head of the medical service of the Swiss army, were appointed to draw up reports on the campaign against syphilis in the civil population and in the army.

DR. FRANCISCO DOMÍNGUEZ ROLDAN, who was recently appointed secretary of Public Instruction and the Fine Arts, one of the highest administrative posts in the Republic of Cuba, is a distinguished member of the medical profession. After graduating at the University of Havana he studied for a long time in Paris, devoting himself especially to anatomy. On his return to his native island he was appointed professor in the University of Havana, and won a great reputation and influence as a teacher.

THE London County Council, at its meeting on April 23rd, agreed to the establishment for one year of an experimental centre for remedial exercises as part of the Council's scheme for the medical treatment of school children. The treatment is intended for the more pronounced cases of such deformities as lateral curvature of the spine, and a voluntary committee is to manage the centre, which will be in Hampstead, where selected children from schools in the district will be sent for treatment.

AT a meeting of the National Baby Week Council on April 11th, under the chairmanship of Sir James Boyton, M.P., it was announced by Dr. Eric Pritchard, chairman of the executive committee, that this year the national celebration would be held from July 1st to 7th, but local committees would be free to choose dates to suit their own convenience. Exhibitions of the practical side of infants' welfare work and mothercraft competitions would be held. It was agreed to co-operate with the National League for Health, Maternity, and Child Welfare. The offices of the National Baby Week Council are at 27A, Cavendish Square, London, W.1.

DISTURBANCES of the reactions of the pupils after recent shell shock without external wounds are probably common, but, as vision is not affected, little attention has been called to the subject. From an analysis of twenty-six cases, Guillaumin and Barré (*Ann. de méd.*, 1917, v, 503-513) find that the following changes may occur: Dilatation, without reaction to light or accommodation; inequality, with failure to react to light on one or both sides; inequality only; the Argyll Robertson pupil; and the paradoxical reaction to light. As a rule, these disorders do not last more than three weeks. The explanation of the pupillary abnormalities is difficult; there is no gross damage to the eye, and there is no evidence that they are hysterical. In six of the cases examined the cerebrospinal fluid was yellow as the result of haemorrhage; possibly in these cases there was a toxin which acted on the roots of cranial nerves or on the fibres of the pupil reflex; possibly the shock affected the retina or the ciliary nerves and muscle, causing asthenia; or possibly there was local compression by blood clot, but in most of the cases there was no sign of meningeal haemorrhage.

Letters, Notes, and Answers.

The telegraphic addresses of the British Medical Association and Journal are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atitology, Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

PART-TIME MEDICAL OFFICERS OF HEALTH.

MEDICUS, in reply to Dr. Lemarchand (p. 350), points out that a doctor may gain or may lose by entering public life, or by holding public appointments. He maintains that if a general practitioner is to be excluded from part-time medical officership of health by reason of the advantage it might give him over his colleagues in private practice, he should equally be excluded from other part-time appointments, such as hospital posts, factory surgeons, etc., and even from taking an active part in municipal or church life.

A CASTOR OIL DRESSING FOR WOUNDS.

DR. JOHN WISHART (Newcastle-on-Tyne) recommends the following method of dressing wounds, which he has used since 1904. He employs castor oil 2 ounces, anaesthetic ether 2 ounces, liq. iodi fort. 1 drachm, and then applies white lint soaked in castor oil. The wounds done in this way only require dressing once weekly, and there are none of the sticking troubles which one has to face in removing gauzes. In circumcision wounds, and ordinary incised and contused wounds, the redressing causes no pain.

VAGINAL DOUCHING.

DR. HENRY DUTCH (London, W.) writes with reference to Dr. W. E. Fothergill's paper (p. 445) on vaginal douching: I have long since recognized the futility of this procedure, which I agree frequently aggravates the condition. The presence of vaginal discharges is very annoying to the patient. Some years ago I suggested a "vaginal applicator," something after the style of Kelly's rectal speculum. This instrument is passed into the vagina by the patient, and a long swab-holder is passed through the speculum, which, gently rotated, brings away any discharge present. I frequently order the swab to be moistened with hydrogen peroxide, which cleans and helps to collect the discharge. It is obvious that something must be done locally to relieve the condition and the patient's mind. The instrument has been made for me by Allen and Hanbury.

TUBERCULIN TREATMENT OF PULMONARY TUBERCULOSIS.

DR. ADAM MOSS (West Kirby) writes, with reference to Dr. A. E. Prest's note (p. 444) commending rest in the treatment of early cases of pulmonary tuberculosis, to state that he treats such cases with tuberculin and lets them go about, and obtains a cure in practically every one. Even in comparatively advanced cases, he continues, with temperature of 100° or 101°, I do not insist on absolute rest. They come to me twice weekly for injections, and rest as much and exercise as much as they feel inclined. Three years ago a man came to me from a sanatorium, which he had entered eight months before as a very early case. His temperature was 101° and the disease so far advanced that I thought it was hopeless to expect a cure. In six months the temperature was normal, and at the end of twelve months I had worked up his dose to 1 c.cm. of old tuberculin. He was then without cough or expectoration and physically absolutely fit. He has done his full work for eighteen months without a day's illness. By all means let the leaders of the profession lay aside prejudice and the rank and file learn how to use tuberculin. I follow Dr. Camao Wilkison's method and I am more than satisfied.

BRANCH SECRETARIES IN THE BRITISH MEDICAL ASSOCIATION.

SURGEON-GENERAL GEORGE J. H. EVATT, M.D., C.B. (Junior United Service Club, London, S.W.), writes: In view of the difficulty that often exists in getting an effective local secretary for a Branch, may I submit the following suggestion? I propose that several Branches should agree to employ jointly a paid secretary, who, living anywhere within the Branch districts, could attend all Branch meetings, and do the secretarial work for all. From secretaries so trained a general secretary might one day be chosen for the British Medical Association. From time to time medical men retire from official medical services with pensions. Such persons, not too old, could well be chosen as joint secretaries of united Branches, and they would, I believe, contribute to the local efficiency of the British Medical Association.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

It was decided at the last meeting of the Executive Committee of the Fund that a second appeal must be made to the medical profession on behalf of our suffering Belgian colleagues, their wives and families. A statement has been widely circulated during the week showing directions in which the large sum contributed to the Fund by the generosity of the medical and pharmaceutical professions has been distributed, and giving also the reasons why every endeavour must be made to maintain the Fund in all its great sphere of utility.

In response to the circular, Dr. H. A. Dea Vœux, the treasurer, is now receiving a large number of subscriptions, so large that only a portion of them can be acknowledged in our columns this week.

Subscriptions to the Second Appeal.

The following subscriptions to the Fund have been received during the week ending April 15th:

	£	s.	d.		£	s.	d.
Lient-Col. G. H. Mott, I.M.S. ...	5	0	0	Surg.-Col. H. Hahgood ...	1	1	0
Dr. John H. Teacher ...	2	2	0	Dr. C. E. Michael ...	1	1	0

				Dr. D. Elcum (for 12 m.) ...	6	0	0

It will be observed with pleasure that the system of monthly subscriptions has begun to attract attention, and it is trusted by the Committee that this method of supporting the movement, which in these times may have its advantages for many willing subscribers, will prove a source of steady income for some time to come. It will be seen that several contributors in sending donations have indicated that although the payment is made in bulk it is to be taken as representing a series of monthly subscriptions; the names occur in both lists of acknowledgements.

Subscriptions to the Fund should be sent to the Treasurer,

Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

DIRECT TRANSFUSION OF BLOOD.

CAPTAIN H. H. KING, I.M.S., writes: With reference to Colonel Hull's article on artery-vein transfusion of blood in the JOURNAL of November 24th, 1917, p. 683, would it not be possible and more convenient to use vein to vein transfusion? If the venous circulation of the donor be obstructed by a rubber bandage round the arm the pressure in the veins of his forearm would, I should think, be quite sufficient to transfer 600 c.cm. or more of blood into a vein of the recipient in a short time. Certainly the venous pressure in the forearm on occasions when I have performed venesection has appeared high. Donors would more readily consent to the ligation of one of the superficial veins of the forearm than allow of the ligation of their radial arteries.

LEMON JUICE IN SEVERE JAUNDICE.

WE are indebted to Dr. J. Pereira Gray (Exeter) for the notes of the following case: I was called a year ago to see a man, aged 72. I was informed by his sister that he was suffering from cancer of the liver and was very seriously ill. The patient stated that his illness was of two years' duration and that he had been seen by five general practitioners and one consulting physician, who were unanimous that he had cancer of the liver. He was given hypodermic injections of morphine three times a week. The skin and conjunctivae were deep yellow. There was a lump the size of an orange in the epigastrium. He was unable to sit up on account of excruciating pain in the dorsal region. The urine was black and the motions white. I told him the former opinions he had as to his condition were probably correct, and by way of treatment advised him to drink daily the juice of half a lemon. Two days later I found the urine had assumed a brown colour and that the man himself felt much better. In a week the urine was amber-coloured. Within a month there was no trace of yellow in the skin or conjunctivae and the lump in the epigastrium had disappeared. There was no pain in the back. Two months later I saw him running to catch a tram. This case shows the proverbial difficulty of definitely diagnosing malignant disease of the internal viscera. It also shows that in all cases of jaundice so simple a remedy as lemon juice is well worth a trial.

UNUSUAL LENGTH OF MENSTRUAL LIFE.

DR. ALEXANDER BLAIR (Helmley, Yorkshire) writes: A patient whom I am now attending has been menstruating regularly, except during pregnancy and the puerperium, for the long period of forty-five years. She informs me that she began to menstruate at the early age of 11 and she is now in her fifty-sixth year. She has been pregnant eleven times and has borne ten healthy children, the confinements being quite normal; the other pregnancy ended in miscarriage at the sixth month. Until the last four years she has lived the healthy life of a busy housewife of the middle class. The periods are still perfectly regular, lasting for about six days. For several years she has suffered from periodical attacks of vomiting, which become intensified, sometimes to a distressing extent, immediately before and during the menstrual period. The condition has persisted in spite of treatment. Some time ago, on my advice, she consulted a specialist, who agreed with my diagnosis of "nervous vomiting probably uterine in origin." The uterus appears to be quite normal with the exception of a somewhat unusual hardness apparently due to fibrosis. Her elder sister began menstruating at the age of 15, and, in her case also, the menopause did not come until she was 56. There is no history of any other female relative having been the subject of such a lengthened menstrual life. The patient is a big woman of fine physique.

AN OBJECT LESSON FOR ANTIVACCINISTS.

The Ohio Public Health Journal for December, 1917, records an instructive example of the danger to which neglect of vaccination exposes a community. A coloured girl from North Carolina soon after her arrival developed small-pox at Waterbury, Connecticut, in June, 1916. The case remained unknown until another person contracted the disease from her. Investigation then revealed ten other cases, all in Waterbury. Other people known to have been exposed were vaccinated and no other cases were reported in July or August. Several other cases, however, came to light in September, and it was found that unreported cases had existed during the preceding two months. From that time onwards further cases were reported in Waterbury and neighbouring towns, and there were others in various places throughout the State of Connecticut. In all but two of these infected localities, however, the exposures were traced to Waterbury. Of the 378 cases reported during the ten months from June, 1916, till March, 1917, practically all were traceable to the coloured girl. Only 10 had been vaccinated within the fifteen previous years. Five of these 10 had been vaccinated thirty years or more before exposure. Waterbury, according to the Secretary of the State Board of Health, has for years been "the Connecticut stronghold for antivaccinationists." It is estimated that only 45 per cent. of its population had been vaccinated at the time of the outbreak of small-pox. Compulsory vaccination of children was not achieved until January 1st. Before that date fifty school children had been

attacked; from January 1st till April 1st not one contracted the disease. In Bridgeport, New Haven, and Hartford, cities with populations of from 110,000 to 150,000, within thirty to thirty-two miles of Waterbury, vaccination had been thorough in the past, the percentage of protected persons being estimated at 80 to 85 per cent. These places escaped infection by small-pox during the Waterbury invasion, except for a single case in Hartford. Not one death occurred in the 25,000 vaccinations performed in Waterbury during the ten months of the epidemic and among several thousand factory hands.

FLAMES FROM WOUNDS.

A STRIKING title to catch the wandering eye is a device well known to the journalist, and sometimes, it must be confessed, the title is the best part of an article. On the other hand, the seeker after curiosities may plume himself, like the successful hunter of bookstalls, on finding a treasure concealed under a modest title. Thus it is surprising to find that Temporary Surgeon K. A. I. Mackenzie's article, "Some Observations in a Recent Action" (Journal of the Royal Naval Medical Service, 1918, iv, 205-6), is an account of two cases of wounds received in action which emitted flames. The first case was that of a leading signalman killed in action and found at the medical distributing station to have a transverse wound on the dorsum of the hand; on separating the apposed edges of the wound a small flame about the size of a finger-nail shot out accompanied by a smell of acetylene; this flame went on for some hours. The second case was also that of a signalman, whose foot, almost blown off, had a similar minute flame in the base of the wound. The explanation was that the men had been standing together at the time when a shell hit a lifebuoy with its attached case of calcium phosphide close to them, and, besides killing one and wounding the other, drove small pieces of calcium phosphide into their wounds. The blood of the wounds made the calcium phosphide burn just as water ordinarily does.

A BOGUS M.D.

AT Greenwich police court, on April 12th, Emmanuel Lawrence, of 195, High Street, Lewisham, pleaded guilty to wilfully and falsely pretending to be, and taking and using the name, title, addition, and description of M.D., thereby implying that he was registered under the Medical Acts. Mr. W. E. Hempson, prosecuting on behalf of the Medical Defence Union, said that defendant was manager to an optician, and it seemed that when people came to him about their sight, his custom was to suggest they were suffering in a manner which called for medical treatment. Defendant professed to have medical knowledge, examined the patients, and gave them prescriptions, which it was contended no chemist would have dispensed unless misled into the belief that they were written by a medical man. It was for this purpose, Mr. Hempson suggested, that the title M.D. was used. Defendant, moreover, charged fees quite equal to those of a general practitioner. In one case, under the guise of being a medical man, he induced a patient to allow him to examine her with a stethoscope, and told her that she had advanced valvular heart disease. This so frightened her that she went to her medical adviser, who, finding no such disease, wrote to defendant, and received an impudent reply. One of the prescriptions contained strychnine in small doses and another nitroglycerin. It was stated on behalf of the defendant that he had borne a good character, was partially paralysed, suffered from heart disease, and his mind was not stable. He had a great idea of his own importance and ability, and a mania for imposing prescriptions upon people, including his own brother. The magistrate observed that the state of defendant's health was irrelevant; he was a most dangerous man, guilty of offences against the Medical Acts, of fraud, and of assaults on women under the pretence that he was a doctor. He imposed a fine of £40, with 20 guineas costs, or three months' imprisonment in default.

NICE AND BOYS.

DR. MILLER (Govan) writes: During my school medical inspection this week a poorly nourished boy was brought to me by his mother. After giving her explicit directions regarding his diet, she told me she had been recommended to give him a field mouse, but had not done so as she thought it would give him "the jaundice."

THE following appointments for certifying factory surgeons are vacant: Motherwell (Lanarkshire), Newton Abbot (Devonshire).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

CEREBRAL OEDEMA (EXCESS CEREBRO-SPINAL FLUID):

ITS CAUSATION AND SURGICAL TREATMENT.

BY

L. BATHE RAWLING, M.B., B.C., F.R.C.S.,

MAJOR R.A.M.C.(T.F.),

SURGEON, WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL.

ON my return recently from India I read with interest an article by Professor Halliburton on the possible functions of the cerebro-spinal fluid.¹ The article terminated with an appeal for closer co-operation between the physiologist and the neurologist in an attempt to elucidate some of the problems relating to cerebro-spinal fluid. May not the surgeon be invited to this conclave? Surely his experience is likely to be of some value, more especially when he has spent a good many years of his life in the study of injuries and diseases of the brain, and when he has practical experience of problems relating to cerebro-spinal fluid. I have discussed such questions for many years in the wards of the hospital; I have demonstrated on many occasions in the operating theatre the existence of *plus* cerebro-spinal fluid; and now, as the result of Eastern experience, I have further points to bring forward showing the conditions that may lead to excess fluid, the pressure symptoms associated therewith, and the results obtained by surgical treatment.

In discussing this excess of cerebro-spinal fluid, I would utilize the original term applied to a description of the naked eye appearances of brain and membranes when soaked in an excess of fluid, "cerebral oedema." It is both comprehensive and expressive, and it harmonizes with my ideas as to causation. It will therefore be retained throughout.

DEFINITION OF CEREBRAL OEDEMA.

To obviate any possible misconception as to what I mean by cerebral oedema, let me first picture the conditions as seen by the veriest novice in any typical case.

When the dura mater is incised in an operation for subtemporal decompression, carried out for the conditions under discussion, clear cerebro-spinal fluid at once escapes from the subdural space, often spurting out as if under considerable pressure. Under normal conditions there is no fluid in the subdural space, and none escapes when the subdural space is exposed. In the event, however, of considerable excess, the cerebro-spinal fluid which normally occupies the subarachnoid space is forced by the increasing pressure between the cells of the arachnoid membrane into the subdural space. This escape of fluid from the subarachnoid space is not problematical. It can be seen in any typical case of cerebral oedema when the dura mater is incised. The arachnoid presents a "weeping" appearance, the tears collecting into rivulets and running away at the lower part of the exposed area. In relation to the cortical veins, lying in the cerebral sulci and embedded in the subarachnoid tissue, little rivers of fluid can be seen with the naked eye, fluid exuding therefrom and contributing to the general pool that collects below. The brain presents a boggy appearance, and the general surface cortical oedema can be very prettily demonstrated by applying gentle pressure with a sponge, the excess fluid being momentarily squeezed aside, to return as a wave so soon as the pressure is removed. The surface of the brain looks like a very wet sponge.

This excess fluid, seen at the operation, will continue to run away during the sewing up of the wound, and that it continues to run away from the surface of the brain into the subtemporal tissues, both during the healing process and subsequently, is shown by the frequent presence in the temporal region of a fluid swelling; it demonstrates the success of the operation, being the proof that the intracranial pressure has been relieved by the draining away of the fluid excess. That this swelling is a fluid collection can be proved directly both by transillumination and by aspiration, and indirectly by means of lumbar puncture. I have frequently carried out lumbar puncture when it seemed advisable to lessen the degree of temporal swelling, the removal of fluid being followed by considerable diminution in the size and tenseness of the swelling. In the more favourable cases, such as those mentioned in this

paper, the swelling is never very marked, and it gradually recedes till eventually the temporal region lies flush with the surrounding area.

If lumbar puncture be carried out in a case of cerebral oedema, as a preliminary diagnostic measure, the excess fluid is demonstrated, both by the pressure under which it escapes and the quantity that can be collected in a given period of time.

CAUSE.

What is the cause of this cerebro-spinal excess? Professor Halliburton, from physiological experiments, states that there are three groups of substances which promote the flow and increase the pressure of the fluid, independently of those which effect it secondarily by altering the blood pressure—excess of CO₂, volatile anaesthetics, and extract of choroid gland or brain. I leave these physiological causes and turn attention to the cerebro-spinal flow in relation to alterations of blood pressure. Professor Halliburton says that the arterial pressure has but little effect on the amount of secretion. I pin my faith, however, on a very definite relation between the amount of cerebro-spinal fluid present intracranially and the intracranial venous pressure, for the following reasons:

1. It is accepted that the cerebro-spinal fluid is formed either as an active secretion from the choroid plexuses of the lateral, third and fourth ventricles, or by a process of filtration through the choroid capillaries.

2. It is accepted that the greater part of this fluid passes from the ventricular spaces through the foramina in the roof of the fourth ventricle to the cerebral subarachnoid system and spaces.

3. It is accepted that it exists at very much the same pressure as the intracranial venous system, but slightly above the venous pressure.

4. It is accepted that, under normal conditions, it is absorbed, as formed, into the cerebral venous channels, more especially into the lateral lacunae of the superior longitudinal sinus. It would be unwise, in the present state of our knowledge, to make any very definite statement as to whether this is a mere mechanical transmission of one fluid of a lower specific gravity and of higher pressure into another, through a permeable wall, or whether the walls of the veins possess a certain selective action. In all probability the vessels do exercise a selective action, but, under the more ordinary conditions, the absorptive process is probably purely mechanical.

Anyhow, this venous absorption, as I may call it, must be dependent on the healthy condition of the walls of the cerebral venous channels, and on the intracranial venous pressure. Consequently, if for any reason the absorptive capacity of the veins is impaired, either by disease or injury, due absorption cannot take place and cerebro-spinal fluid collects in excess in all possible spaces—in the subarachnoid system, in the ventricles, on the surface of the brain and in the subdural space, producing, as a result, a typical state of cerebral oedema.

For example, if, as the result of heat-stroke, the tunica intima of the cerebral sinuses and veins is impaired, temporarily or permanently, cerebro-spinal fluid will collect in excess. Again, if as the result of some head injury the intracranial venous pressure is considerably raised, so as to be well above the tension of the cerebro-spinal fluid, the normal rate of absorption of cerebro-spinal fluid will be impeded, and it will collect in excess.

There is a third hypothesis, that toxic conditions, acting on the choroid plexuses, lead to an increase in the rate of secretion. Of this, however, there is no considerable evidence.

In the earlier stages of cerebral oedema the excess fluid will escape in the following manner: a small quantity passes down the neural canal, to be withdrawn, perhaps, by lumbar puncture, with some temporary relief to the increasing intracranial pressure; a still smaller quantity permeates through the various emissary channels at the base of the skull, to be absorbed by the extracranial venous channels. As the fluid increases in quantity these means of escape prove inadequate, and it accumulates first in the subarachnoid region, bogs the surface of the brain, and finally exudes through the arachnoid into the subdural space, giving rise to the typical picture of a case of cerebral oedema.

Some further light is thrown on the question by my work in the East. A large number of cases were admitted

to hospital with the diagnosis "heat effects," the great majority coming from Mesopotamia, in batches according to the climatic conditions prevailing in that country. It is obvious that many difficulties were encountered when we endeavoured to classify these cases and group them according to the diseases from which they really suffered. Some proved to be malarial, others were suffering from diseases of the typhoid group, and so on, but there remained a considerable number, running into hundreds, who proved negative to all tests, and concerning whom, therefore, I retained the original diagnosis (heat effects).

SYMPTOMS.

The symptoms from which these men were suffering were as follows:

1. Headache, and General Mental Condition.

Headache, dating from the beginning of the attack, was very severe at first, and then became chronic. When in hospital it was observed that the men were very listless, disinclined to leave the ward, and then only after the heat of the day. They suffered from more or less persistent pains in the head, and were indeed seldom free from headache. They were always worse towards the evening, especially between 5 p.m. and 8 p.m. The pain was usually frontal. During the many exacerbations, the men sometimes retired to bed or to the quieter and darker parts of the ward, disliking the light and their fellows, and burying their heads beneath the bedclothes. They were irritable and despondent. Drugs were of little avail for the relief of the headache, procuring only temporary alleviation at the best.

Operative measures, when proposed, were usually accepted with eagerness, and in some two or three cases the men implored me to do something, at whatever risk, for their relief. The general severity of the headache and the mental effects produced on the patients can be gauged by this ready acceptance of operative measures.

2. Vomiting.

This was present only in the worst cases, and then only in definite relation to the exacerbations of headache. Nausea, of the "sick headache" type, was almost constantly present.

3. Ocular Changes.

Photophobia, more especially during the heat and glare of the day, was a marked feature. True papilloedema was never observed. Every case was examined by our ophthalmologist, but, with the exception of a few in which the retinal vessels appeared rather fuller than usual, there was no definite fundus changes. I anticipated more, in view of the very definite relation between papilloedema and considerable increase of intracranial pressure. However, as papilloedema is not necessarily present in intracranial new growths, even when of considerable size, the absence of any fundus changes in the cases under discussion is quite explicable.

4. Pulse-rate and Blood Pressure.

During the exacerbations of headache the pulse-rate was slowed to 50 or 60, and the systolic blood pressure raised to 140 or 150 mm. Hg—no great rise of blood pressure, but, by taking controls, it was found that the average blood pressure of patients in India was below the normal.

5. Reflexes.

There was a marked tendency to exaggeration of reflexes, both superficial and deep. The men themselves were very shaky and nervous, with tremors of the hands, etc.

6. Temperature.

The temperature was slightly raised as a general rule, with further elevations during the more severe periods of headache, etc.

7. Epileptiform Convulsions.

Epileptiform convulsions occurred in eight of eleven cases here recorded—an unusually high percentage, but capable of explanation. The convulsions were sometimes of the most violent description, each succeeding attack tending to be more severe than the preceding. The men usually knew when to expect the seizure, warned by some excess of headache, curious tinglings, etc. Consciousness was not always lost, the senses perhaps being sometimes

retained throughout a mild attack, and in the early stages of the more severe fits. The duration was variable—from five minutes up to three hours. These men required supervision, and during the convulsions as many as five men were required to hold them down and protect them from self-hurting. Lips and tongue were seldom bitten. Frothing at the mouth was unusual. Struggling was violent, and the face was markedly congested. The blood pressure was raised, and the pulse-rate slowed. After the convulsion was over there was much prostration, sometimes lasting two or three days, associated with headache.

In frequency the fits varied; sometimes a day or two intervened between the attack, or the patient might be free for a week or more.

When the attack lasted two to three hours the patient passed from fit to fit without regaining consciousness. The convulsions were general and it was quite exceptional to see any localizing features.

Several of the cases in which these epileptiform convulsions were observed gave a previous history of brain disturbance of some sort or other—fits, brain fever, head injury, etc. In three cases only were the men normal in every respect. This rather strengthens my views as to the cause of cerebral oedema. If the excess cerebro-spinal fluid is dependent on deficient absorption into the cerebral venous channels, it is only to be expected that antecedent injury or disease would add to the liability to the conditions as pictured. The strain of active service, heat-stroke, shell shock, overwork, etc., would still further impair the rate at which the fluid is absorbed and tend to the accumulation of cerebro-spinal fluid and the advent of definite cerebral oedema.

Interpretation of Symptoms.

All these symptoms, pointing as they do to a general increase of intracranial pressure, together with the *plus* cerebro-spinal pressure (lumbar puncture), and the very satisfactory results obtained by decompression, show that the excess of cerebro-spinal fluid was directly responsible for the development of the symptoms enumerated. Pressure alone might suffice to produce the convulsions, exercised as it was on a highly excitable cortex, the result of heat-stroke, cerebral malaria, etc. It is possible, however, that certain toxic products contained in the fluid may have led to the development of these explosive attacks. Still, by reason of the immediate benefit obtained in every case by simple drainage of excess fluid and the normal characteristics of the fluid collected at the operation, I am inclined strongly to the view that pressure alone sufficed.

TREATMENT.

Many cases presenting these symptoms were admitted to hospital during my fifteen months' service in the East, and seven were submitted to operation. I give a short account of the first case so treated, with an abstract of the six other cases, and, as a control, a brief account of four cases refusing operation.

CASE I.

A R.A.M.C. orderly was admitted to hospital at Amara, Mesopotamia, on June 10th, 1915, suffering from heat-stroke. After recovering he was put on light duty in the wards. There he had several fits which were not controlled by bromides, etc. He was invalided to India; he suffered from two fits at Basra whilst awaiting ship, and one during the voyage. He was admitted to hospital in India on August 13th, 1916, complaining of severe headache, with ready excitement and frequent prostration. His eyesight was said to have been failing for the past few months. The retinal veins were rather dilated and tortuous, especially on the right side. The headache persisted throughout the day, becoming worse in the evening. It never actually left him free, and there were marked exacerbations. All reflexes were *plus*. Tremors of the limbs on exertion. Blood pressure equal to 150 mm. Hg. The pulse-rate tended to be slow during periods of headache. The temperature was never above 100°, and was usually normal.

August 18th. Fit, heralded by abdominal pain and tightness of the chest. Did not lose consciousness; fit lasted fifteen minutes. Twitching of limbs general, then stiffness and general rigidity, followed by severe headache.

August 25th. Severe headache and feeling of a fit coming on. Staved off by walking about.

September 2nd. Severe headache which preceded a violent epileptiform seizure; first clonic spasms of arms, then tonic contraction, spreading to both lower extremities and equal on the two sides. Conscious during the first part of the fit, then senses lost. Fit lasted thirty minutes. Restless afterwards, with severe headache.

September 6th. Numb feelings in both hands, but fit staved off as before.

September 7th. Another fit, more intense and violent than any previous one. Lasted an hour and a quarter. Strugglings very violent, requiring control from four orderlies and convalescent patients. Quite unconscious the whole time. Did not bite tongue. Did not pass urine or motion.

September 14th. No more fits, but headache very violent at times. Getting depressed and miserable. Keeps to bed and sheltered parts of the ward.

September 15th. A still more severe fit, lasting an hour and a half. Very fierce strugglings. Quite unconscious. Followed by headache even more severe than before.

Operation.

Lumbar puncture showed great increase of cerebro-spinal fluid tension and amount. Fluid otherwise normal. Operation advised, and the idea readily accepted by patient, who was willing to undergo any treatment for the relief of headache and fits. I had watched this man daily since his admission and had ordered all available narcotics, with but the slightest momentary effect. For three days previous to operation I kept him under the influence of morphine in order to cut short the possible development of further fits, the result of the operation being obviously more hopeful if performed during a more or less quiescent period. The diagnosis appeared reasonable that, as the result of heat-stroke, the patient was suffering from cerebral oedema, with great excess of cerebro-spinal fluid.

On September 21st I carried out a right-sided subtemporal decompression, choosing that side on the ground that the retinal veins were the more engorged in the right eye. The bone was cut away so as to leave a gap of about two and a half inches in the antero-posterior direction and one and a half inches in the vertical. The dura was opened the full extent by crucial incision. Cerebro-spinal fluid spurted out when the dura was opened, the arachnoid wept copiously, and fluid ran away in rivulets—a typical picture of cerebral oedema.

After-History.

With the exception of some neuralgia and pain in the right face, a common result after subtemporal decompression, due in part to the interference with the temporal muscle, the patient was practically relieved of headache the following day. There was no headache, except of a very mild character, and no fits developed from the day of operation till his arrival in England three months later. The further history of the case is scheduled towards the end of this paper.

Shortly afterwards other cases were admitted to hospital with similar symptoms, some of a mild character, others very severe. The general pressure symptoms were more or less identical, merely varying in degree. There were eleven serious cases, nine with epileptiform convulsions; seven were subjected to operation, and four refused surgical treatment. All cases were watched for an average period of three months, and previous to operation all other known remedies were given full trial.

CASE II.

Fits began at the age of 12. Joined in 1914, but was sent home because of the fits. Rejoined in 1916 and was sent to India. Later, when in Mesopotamia, the fits recurred and became much worse than before, the result, as attributed, of an attack of heat-stroke. The fits were associated with giddiness, headache, and vomiting; they were preceded by attacks of blindness or giddiness, and sometimes lasted forty-five minutes; consciousness was not always lost. When in hospital he had fits on several occasions, three or four days usually intervening. All were very severe and headache was more or less continuous.

Subtemporal decompression, right; much fluid escaped on opening the dura, the arachnoid weeping, etc. No trace of headache, and neither fits nor vomiting subsequently. (Further history below.)

CASE III.

Patient, aged 19, had suffered from fits for many years; infrequent occurrence, but much worse after service in Mesopotamia. Many fits when in hospital, all typically epileptiform. Headache very severe. Subtemporal decompression brought about great relief, and during the two months' residence in hospital after operation the fits became ever less intense and less frequent. (Further history below.)

CASE IV.

Said to have enjoyed excellent health till December, 1916, when, whilst carrying rations during the heat of the day in Mesopotamia, he had a fit, diagnosed as heat-stroke. Mentality poor, headache more or less continuous and very severe at times. Several fits after admission, with loss of consciousness and followed by severe headache. The fits tended to become more severe, the most serious lasted one to two hours, fit following fit, with subsequent prostration. Subtemporal decompression revealed a typical condition of cerebral oedema. After the operation, quite free from headache and fits till leaving hospital. (Further history below.)

CASE V.

Patient had an attack of meningitis when 14 years of age, since when he had suffered from periodic attacks of headache. After service in Mesopotamia he became very much worse. Headaches were very severe, and he declared that his life was not worth living. After several weeks of treatment, he accepted

readily the chance of improvement by operation. Subtemporal decompression showed a condition of typical cerebral oedema and, after the operation, he rapidly improved. Mentality good when discharged, and there were neither headaches nor fits. He said that he was free from headaches and happy, the first time since he was 15 years of age. (Further history below.)

CASE VI.

In this case there was a history of injury to the head some years previously. For some time he had suffered from periodic headaches and vomiting, both of which became much worse in Mesopotamia. Subtemporal decompression showed typical cerebral oedema. He was completely relieved. (Further history below.)

CASE VII.

Quite well in every respect till heat-stroke in Mesopotamia, falling down in the heat of the day in a fit which lasted twenty minutes. A second fit, of three hours' duration, six months later. Subsequently an average of three fits a month. Then invalided to India. During stay in hospital fits became very much more frequent and more severe. Consciousness lost on most occasions. Fits lasted sometimes two to three hours—a succession of fits. Subtemporal decompression showed typical cerebral oedema. No fits afterwards and headache almost entirely relieved. (Further history below.)

As a contrast to these seven cases, I have the notes of four who refused operation. They presented similar symptoms; both fits and headache became more severe and more persistent as the days passed by. I urged operation, guided by my previous experience, but all surgical remedies were refused. The four patients were eventually discharged in a rather pitiable condition.

Reasons for Subtemporal Decompression for Cerebral Oedema.

The drainage of this excess cerebro-spinal fluid, the result of deficient absorption into the cerebral venous system, by means of trephining and dural opening, permits of the escape of the fluid from the confined space in which it is pent up and allows of its coming into contact with new tissues where it can be absorbed. The primary cause (? temporary or permanent changes in the walls of the cerebral veins) is beyond the scope of surgery, but, by the relief of the general pressure symptoms, time and opportunity are afforded for some recovery on the part of the defective venous system, and, if that does not happen, a secondary path of escape has been made for the superabundant fluid.

All the cases that came to operation, both in India and since, recovered, so that I have not yet had the opportunity of putting my views to the test by obtaining microscopic evidence as to pathological changes in the cerebral veins. And, so far as I can see, there should be considerable difficulty in proving my point—there should be no mortality connected with the operation.

Lumbar Puncture.

Lumbar puncture, however frequently repeated, cannot be expected to bring about more than a temporary improvement at the best. This was my experience in several cases. More radical measures are required for the relief of the accumulating fluid.

In addition, there are two points concerned with lumbar puncture which are disconcerting. Firstly, I found that lumbar puncture sometimes made the patients worse, in spite of the fact that a good deal of fluid was withdrawn—one to two test tubes full; and, secondly, lumbar puncture sometimes failed to show any excess at all, but rather the reverse. In one of my last cases, four punctures carried out immediately previous to operation showed a great diminution in the amount of cerebro-spinal fluid; and, in the operation performed immediately afterwards, the opening of the dura showed a most typical condition of cerebral oedema, with very great excess of fluid. Possibly some swelling of the membranes in the region of the fourth ventricle, together with considerable local excess of fluid, closes the normal communication between the cerebral and spinal arachnoid system. Consequently, although lumbar puncture should be carried out in every case, the absence of fluid excess does not by any means negative the diagnosis of cerebral oedema. The general clinical symptoms are a far surer guide.

Indications for Operation.

Operation is indicated in severe and intractable headache, with or without epileptiform convulsions, whether due to heat-stroke, cerebral malaria, shell shock, or neurasthenia. It is obvious that in every case all

ordinary remedies, including prolonged rest in bed (the most important of all), should receive a fair trial, but in view of the injurious effect produced on the cortical cells by prolonged soaking in superfluous fluid, operative measures should not be unduly delayed. I would suggest three months as a fair probationary period.

Region Chosen for Decompression.

The temporal region offers the most suitable site for decompression. The operation is carried out over a silent area of the brain; drainage is conducted at the most dependent part of the brain; the scar is hidden subsequently by the hairy scalp; the bone defect is in a reasonably safe situation, and the operation involves no special risk when carried out by one possessing reasonable skill in head operations. The right or left side is chosen according to the distribution of the headache, but if there is no such localization the right side should be selected to avoid any possibility of disturbing the functions of the motor speech area.

The Opening in the Skull.

The trephine opening should be made low down, immediately above the ear, in the angle between the anterior and posterior branches of the middle meningeal artery. The opening is enlarged mainly in the anterior and posterior directions and downwards towards the base of the cerebral fossa. The bone is cut away so as to leave an aperture not less than two inches in the antero-posterior direction, one and a half in the vertical. The size, however, varies—the more severe the symptoms the larger the opening, and vice versa.

The dura is opened in every case by crucial or other incision. The intradural tension is *plus*, and in consequence the dural incision must be carried out with caution to avoid damage to the underlying cerebral vessels. The temporal muscle, turned down previous to trephining, is sewn into position at the end of the operation. Drainage to the surface should never be employed.

After-Treatment.

The patients should be sat up in bed as soon as possible. I advise small doses of morphine for one or two days following the operation, then bromides for a week or two; they should be gradually discontinued. Patients should be kept quiet in hospital for one month and then sent for prolonged convalescence at some quiet place with open-air treatment and no worries.

Plating the Gap in the Skull.

The situation of the opening, its muscular covering and subsequent protection with the fibrous tissue that develops later, usually render subsequent plating unnecessary. In some cases, however, especially when an extra large opening has been made, protection with a plate may be required. This can be done after the lapse of six months or so.

RESULTS OF SUBTEMPORAL DECOMPRESSION FOR CEREBRAL OEDEMA.

Immediate.

In the seven cases submitted to operation immediate benefit resulted. In some the patients were quite free from headache the day after the operation, the first time for many months. In other cases two or three days elapsed before real improvement occurred. In all cases, however, headache of any severity was a thing of the past. Minor attacks occurred now and then, but nothing compared to the previous severity. As regards the epileptiform convulsions, in spite of the fact that in some cases the fits had been not only numerous and severe but also dated back for some months, and even longer, there were no further fits of any sort (except in Case III) from the time of the operation till the discharge of the patient from hospital, an average period of two months. The mental condition improved in direct ratio; patients previously miserable and depressed became bright and cheerful, eager to get home. All other pressure symptoms disappeared in direct proportion.

Remote.

The later histories of these seven men confirm, with certain modifications, the early results as expressed above. All seven cases arrived home, and communications have

been received carrying on the history of the case down to eighteen months subsequent to the operation, thus giving a reasonable guide as to the result of the measures carried out.

CASE I.—“I am glad to say that I am fairly all right so long as I keep quiet. I often get a head, but nothing like the old days in India. Have only had about four attacks since arriving home.”

CASE II.—“Sometimes I am well in my head and sometimes I am so bad that I cannot do anything. The fits I have not had any more.”

CASE III.—“I am very well sometimes, at others I cannot do anything. I have had no more fits.”

CASE IV.—“I am getting on quite well, and my master is very pleased with my work. I hope you are in the best of health, as it leaves me at present.”

CASE V.—“I am thankful I am able to give you a good report. My head gives me no trouble whatever beyond an occasional headache, which all of us are liable to at times.”

CASE VI.—“I am keeping fairly well. I am getting pains and sickness now and then in dull weather. I get dull headaches, but nothing to worry about.”

CASE VII.—“Up to the time of writing I have had one or two attacks, the last in August of last year, since when I have been in the best of health.”

The first three cases are less satisfactory than Cases IV to VII. This, I believe, is due in the main to the experience gained in the earlier cases, as to points in the operative method, more especially in reference to the size and position of the decompression opening in the bone. But, taking all things into consideration, these results may be regarded as highly satisfactory.

Finally I would add that I have carried out the same operative procedures on three cases recently for chronic headache the result of eight gunshot wounds, being blown up, buried, etc. Two of these men were operated on very recently. In both the early result is eminently satisfactory. One man, the last case, said to me this morning: “My headache is all gone, and I feel a treat.” This man had been blown up and buried, and had suffered from headache for five months.

REMOVAL OF WORM (FILARIA LOA) FROM THE EYE.

BY LIEUT.-COLONEL R. H. ELLIOT, I.M.S.(RET.).

Mr. T. W., of the West African Civil Service, was sent to me by Dr. C. W. Daniels on April 2nd, 1918, suffering from a worm under the conjunctiva of the right eye. The patient is highly intelligent and educated. In addition he is an excellent observer, and has taken a very close interest in the evolution of his case, with the result that he has been able to contribute some new and interesting items of information on the subject of this form of filariasis.

History.

He believes that he contracted the disease in Benin City, where he was resident for eleven months (from June, 1909, to May, 1910). He knows of two other Europeans who contracted it whilst there with him, and he considers the district the commonest endemic centre of the disease in West Africa. He has discussed the disease with Sir Patrick Manson, Dr. Daniels, and other well-known authorities, and has taken considerable interest in the flies responsible. He recognized *Chrysops dimidiata*, figured on page 783 of Manson's *Tropical Diseases* (sixth edition), as a very common pest there; he states that this fly is of a yellow colour, and that it settles on its victim “in a very sly and unobtrusive manner, in this resembling the tsetse fly.”

The first signs of infection he exhibited were calabar swellings in the hands and feet; these began ten months after his arrival in Benin district, and have continued off and on up to the present time, but latterly they have only attacked the hands. He describes them as very painful, and complains bitterly of “the tightness of the skin over them.” The first really bad one of these attacks was thirteen months after his arrival in Benin; the previous ones had been quite slight.

His next trouble was the appearance of the worms in and about the eyes. This commenced very shortly after he first noticed the swellings, and has continued off and

on throughout the whole of the past eight years. Although he has felt the worms moving about in various parts of his body, they have occasioned him comparatively little inconvenience, except when they have invaded the neighbourhood of the eye and ear. In the former situation they cause great irritation, which becomes intense when they find their way under the conjunctiva. The combination of itching, pain, and irritation caused by their movements he describes as "simply maddening." He has learnt to obtain sleep during these attacks by instilling cocaine into the eye, and he believes that, apart from the anaesthesia of the conjunctiva, an important accessory action is the toxic influence of the drug on the parasite, causing it to become sluggish and abate its movements.

In this connexion he quotes an interesting and suggestive experience, which might possibly be followed up with advantage by surgeons. On one occasion, on embarking for England on leave, he consulted the ship's surgeon on account of a *Filaria loa* in his upper lid; full of enthusiasm, the surgeon gave a subcutaneous injection of cocaine, and completely lost the worm in the resulting oedema, though he cut down upon it. When the swelling subsided the patient felt a hard linear mass lying in the position the worm had occupied at the time. Subsequently, while he was home on leave, "a cyst developed at this spot, and was incised and scraped out by a surgeon." He does not think any effort was made to ascertain the contents of the cyst, but he is absolutely satisfied in his own mind that the hard linear mass he felt was the dead worm, and that it had been killed by the cocaine injection. The suggestion seems likely to be correct, and is supported by the writer's experience with cocaine to be mentioned later in the paper. Mr. T. W. has had worms removed from his eyes on four previous occasions—namely, once in 1911, twice in 1914, and once in 1917.

The patient's observations on earache, caused by the *Filaria loa*, are the more interesting, because this would appear to be the first time that any account of the kind has been placed on record. The earache, from which he has suffered on several occasions, consists of an intense neuralgia behind, below, and in front of the ear, and is accompanied by great hyperaesthesia of the skin in these neighbourhoods. These attacks are so definite that he is able to diagnose their cause without hesitation. On the present occasion, the trouble began with earache on the night of April 1st, which led him to remark to his wife, "I am sure this is another of those beastly worms." A few hours later the pain passed away with a suddenness which he has learnt to regard as characteristic of such attacks, and he then felt the worm moving about in the neighbourhood of the orbit of the same side (the right).

The visits of the worms to the surface occur with great irregularity. Sometimes he feels nothing of them for months at a time; then he may have trouble for varying periods of from one to ten days or more. He is quite unable to say what brings on the attacks, though he thinks

that some of the worst have been at the commencement of the hot weather. Questioned as to the influence of the heat of fires in drawing the worms to the surface, he had no evidence to give, but added that possibly this was because he "had seen so little of fires for many years." The rate at which the worms travel is considerable; in the loose tissue round the orbit, he has felt them pass from one side to the other in the course of a few minutes; there is always, however, the possibility that more than one worm may be present, though he does not admit this as an element of confusion, stating he can "feel the brutes travelling." He has noticed on at least two occasions before the present, that the removal of one worm from the eye has been followed by the appearance of a second

FIG. 1.—Adult female *Filaria loa*, 36.5 mm. long; the mouth end is to the left; magnified ($\times 2$).

FIG. 2.—The mouth end of the worm ($\times 10$).

FIG. 3.—The tail end, showing the opening of the ano-genital orifice ($\times 10$).

The present, therefore, makes his fifth experience of the kind. All the others were, however, extracted from his lids. This was not because the worms did not pass under the conjunctiva, but for other reasons. Thus, he had several times travelled long distances to consult a doctor, only to find the worm had gone deep again when he arrived. On other occasions medical men, who were willing to remove the visitor from skin areas, declined to interfere with it on the eyeball. He has had a variety of experiences, owing to the fact that some of his surgeons were ignorant of the habits of this parasite. Thus, one seized the worm in a pair of forceps and cut down on it, but released his grip of the animal before he had captured it with a fresh pair of forceps, and to his chagrin saw it disappear from his sight. Another tried to cut down on it without first fixing the worm, and was naturally disappointed with the result of his operation.

parasite on the following day, and he suggested that probably they were a pair. On this occasion one worm was removed on April 2nd, and he was feeling a second round the opposite eye all the following morning. On several occasions previously he has felt two worms at one time, one round each eye.

Two explanations of this phenomenon suggest themselves: (1) That the conditions, atmospheric or otherwise, which attract one worm to the surface, might equally readily attract two or more, and (2) the idea, suggested by the patient, that the second worm is a male with nuptial designs following the first, a female, in the course of her peregrinations. The explanations are on all-fours with those which cover the well-known Indian experience, that if one kills one snake near one's house, one must be on the look-out for its fellow shortly afterwards.

An interesting feature and one very difficult to explain is that the worm which was removed in 1911, that is, within two years of the first possibility of infection, was 60 mm. in length, whilst this one, removed seven years later still, was 36.5 mm. long, and the others, removed in 1914 and in 1917, have all been shorter than either of these. From the commonly accepted views, one would rather have expected to find an increase in the size of the worms extracted as years passed by.

The patient was sent home from West Africa for a low form of fever, with evening temperatures of from 99° F. to 100° F., which, it has hesitatingly been suggested, might be due to filariasis.

Operation.

The patient was sent on April 2nd, 1918, by Dr. Daniels, who had seen the worm in the eye, and advised immediate extraction. On examination, the conjunctiva was congested, but no worm could be seen. The patient stated that it had just left the eye, but that he believed it might come back. He felt it moving about, and seemed to have no difficulty in localizing it. At one time he said it was in the outer part of the upper lid near the skin; shortly afterwards it was close to the conjunctiva above the inner canthus; then it had passed over again to the outer side of the eye, but this time just below the lower fornix. After waiting some time, there seemed little hope of it appearing, and so, acting on the knowledge that these worms tend to come to the surface under the influence of heat (as has been shown by their causing eye trouble when the patients sit before a warm fire), hot fomentations were applied. Very shortly afterwards the worm could be seen wriggling freely in long sinuous loops beneath the conjunctiva, below and close to the cornea. Cocaine was instilled, the patient was told to look up, and the lower lid was pulled down. The interference alarmed the worm, which quickly endeavoured to escape, its movements being extraordinarily rapid, but just as it was disappearing under the dense tissue of the lower fornix a dive was made for it with a pair of conjunctival forceps. It was difficult to say whether it had been caught or not, but a curved needle armed with a silk suture was passed through the fold of conjunctiva included in the grip of the forceps; the suture was tied tightly and the forceps removed. For some time no movement could be observed, and the patient suggested that this was due to the toxic action of the cocaine on the animal; but an elongated oedematous swelling on either side of the suture suggested that the worm had been caught. The conjunctiva was thoroughly anaesthetized, and blanched with cocaine and adrenalin, and the part was kept under careful observation by a nurse. Suspicious movements were noted from time to time. On manipulating the suture, one end of the worm was suddenly seen, freely moving to the inner side, and was at once seized through the conjunctiva with a pair of conjunctival forceps. A small incision was made with scissors, and the coils of the worm could then be recognized through the sub-conjunctival tissue; suddenly one end wriggled itself free, and stood right out from the wound; it was seized with a pair of forceps, and gently drawn upon. The tightness of the suture was such as to prevent the worm from getting free by its own efforts, but it added very little to the difficulty of extraction.

The specimen was placed in 5 per cent. formalin, and was photographed shortly afterwards. On removing it, what looked like another small worm was found lying imbedded in mucus in the lower cul de sac of the conjunctiva. This presented a curled-up end, and distinctly was either part of a small worm or was the macerated end of a larger one. This small mass was unfortunately lost, owing to an accident. The larger worm was a well-grown female *Filaria loa*, showing some embryos in its uterus. When fresh it measured 36.5 mm. It is shown in Fig. 1, double the actual size. Figs. 2 and 3 show the head and tail ends of the worm respectively, under a magnification of 10 diameters.

Unfortunately no examination of the blood was made.

A VACCINE for the treatment of dysentery, prepared in Hamburg, and called "Ruhrheilstoff-Boehnecke," has been recommended in a Government order of December 15th, 1917. It is said to differ from an earlier preparation with the same name in containing no free dysentery toxin. The therapeutic results are said to be good.

THE PROGNOSIS IN WAR NEPHRITIS.

AN ANALYSIS OF 171 CASES.

BY

RODOLPH G. ABERCROMBIE, M.D.,

TEMPORARY CAPTAIN R.A.M.C.

WITH the aid of the Medical Research Committee the subsequent history has been investigated in an unselected series of 171 cases of war nephritis.

During their initial stage the cases had been under my care in a base hospital in France, to which they were admitted between April, 1915, and February, 1916, inclusive. Their after-histories have been traced until November, 1917—that is, for periods varying from twenty-one to thirty-two months. The symptomatology of the cases has been previously fully detailed.¹ Their initial stage was an acute illness, exhibiting albuminuria with oedema.

Mortality.

Six deaths occurred: one in France, three in English hospitals, and two after discharge from hospital in England.

Results of First Period of Home Treatment.

From France the cases were evacuated to English hospitals, from which they were discharged direct, or transferred to convalescent hospitals or command dépôts. Taken together, this comprised the first period of home treatment; the results of it were as follows:

- 32 men were invalided as permanently unfit on account of nephritis (23 being invalided from hospital, 3 from convalescent hospital, 4 from command dépôt, 2 from Canadian Casualty Assembly Centre).
- 131 were discharged to some form of duty.
 - 1 was discharged from command dépôt for rheumatism.
 - 1 was discharged on termination of engagement.
 - 3 died in hospital.
 - 1 died after having been discharged to light duty.
 - 1 died after having been invalided.

The last two cases have been included only amongst the deaths. In the case of seven men who had been discharged from hospital to duty, the subsequent history could not be traced for various reasons; these seven men have therefore been altogether excluded from the series.

Subsequent History.

Of the 131 cases discharged to duty, 22 subsequently either relapsed or showed chronic renal symptoms, and were ultimately invalided for nephritis; the remaining 109 showed no further history of the disease.

Table giving Percentages of Results in the whole Series.

	No. of Cases.	Percentage of whole Series.
Died	6	3.5
Invalided for nephritis during first period of home treatment	32	18.7
Returned to duty, but subsequently invalided for nephritis	22	12.8
Showing no further history of nephritis ...	109	63.7
Variously accounted for... ..	2	1.3
	171	100.0

Adding together the deaths, the number invalided during the first period of home treatment, and those invalided after return to duty, the total loss was 60 men, or 35 per cent. of the whole number.

The average stay in hospital and convalescent hospital (excluding command dépôts) during the first period of home treatment was for all cases 89 days; for the cases invalided during the first period of home treatment, 130 days; for those invalided after return to duty, 107 days; for those returned to duty and showing no further nephritic history, 72 days.

With regard to the 22 cases returned to duty but subsequently invalided, the average interval between discharge from hospital and final invaliding was six months. Of these cases 12 were readmitted to hospital; 10 were invalided by medical boards without readmission to hospital; the final breakdown must therefore frequently have been due to gradually developed renal symptoms rather than to definite relapse. Since cases are also invalided from command dépôts without readmission to hospital, it is evident that the study of hospital readmissions affords

only imperfect evidence of the invalidism following nephritis.

With regard to the 109 men who showed no further nephritic history, their military efficiency cannot be exactly stated. Approximately, 79 became first-line troops, 30 being relegated to garrison duty or some form of home service. These 109 men are not, of course, all still in the service; 8 have been killed, others wounded, gassed, made prisoners, and 3 invalided for diseases other than nephritis.

The number of cases known to have proceeded again overseas on military service is 71; of these, three relapsed in France, one man having had three distinct attacks. None of these three men had had nephritis before the war; all were ultimately invalided.

The different hospitals varied greatly in their handling of the patients: some cases were kept in hospital for long periods; others were discharged to duty after a few days, frequently relapsing; others were invalided after two or three months in hospital, not having had time to recover. One case invalided as permanently unfit showed no evidence of disease on medical examination about a year later.

Influence of Age on Prognosis.

The cases have been arranged in five groups, according to age; the numbers and percentage of the loss from death and invaliding due to nephritis are given in each group.

Age Groups.

	Under 26.	26-30.	31-35.	36-40.	Over 40.
Number of cases...	46	45	42	21	15
Loss due to nephritis ...	13	12	14	6	10
Percentage of loss ...	39	25	33	28	66

The cases over 40 thus did badly; and the youngest group also showed higher invalidism than the remainder. The fatal cases were aged 54, 39, 38, 32, 29, 20.

Influence of Previous Attacks.

Of the cases, 32 gave a history of previous renal disease; of these, 2 died, 10 were invalided during the first period of home treatment, and 4 were invalided after returning to duty, making a total loss of 16, or 50 per cent. In one of the invalided cases the previous attack had been in France during the war.

In 134 cases no previous renal history was obtainable; of these, 4 died, 22 were invalided during the first period of home treatment, and 18 were invalided after returning to duty—a total loss of 44, or 32 per cent. In 3 cases, all of whom recovered, information as to previous attacks was not recorded.

Prognostic Indications during Initial Stage.

Prolongation of the initial stage is unfavourable. The cases were not evacuated from France until free from oedema and uraemic symptoms, and until the urinary flow was re-established; the average period from the onset (as given by the patient's history) to the date of evacuation was twenty-four days. Of 68 cases in which this period was above twenty-four days, 50 per cent. died or were invalided; whereas of 97 cases in which this period was twenty-four days or under, only 27 per cent. died or were invalided.

Cases showing severe uraemic symptoms during the initial phase are slightly more unfavourable with regard to remote prognosis than the ordinary type of case. Five of the cases had convulsions in France; of these, two were ultimately invalided, and three returned to duty, two of them proceeding again overseas. Eight cases showed other severe uraemic symptoms (deep torpor, twitching, amaurosis); of these, four were ultimately invalided, and four returned to duty. Convulsions were thus less unfavourable than other severe uraemic manifestations; this accords with the observation¹ that after convulsions a severe case often begins to improve rapidly.

Definite ascites is unfavourable; of fourteen cases, eight were invalided. The abdominal tumidity sometimes mistaken for ascites has no prognostic importance.

No special symptoms marked the initial stage of the fatal cases.

Pathological Sequelae.

Cardio-vascular changes were noted in the hospital records or invaliding documents of fourteen cases, in which

such changes had not been observed during the initial phase.

Tuberculosis appears to have a definite consecutive association; in one fatal case, dying seven weeks from the onset, early active tuberculosis of the lungs was found in addition to nephritic lesions; in a second case, invalided for nephritic symptoms one year after the onset, tubercle bacilli were present in the sputum at the time of invaliding; a third patient, who during the initial stage had shown typical renal dropsy, was invalided for tuberculosis of the kidney and epididymis nine months after returning to duty; and a fourth case was invalided for pulmonary tubercle about a year from the onset of nephritic symptoms.

Persistent albuminuria was the most frequent cause of invaliding.

Prognosis in "Lower Tract" Nephritis.

This name has been suggested¹ for a condition, not uncommon in France, of febrile haemorrhagic pyelitis, sometimes associated with cystitis, tending to relapse, showing neither oedema, uraemic symptoms, nor raised blood pressure, but with urine containing granular casts. Six such cases (not included in the series) have been traced. Five returned to and remained at duty; one, aged 38, was invalided for headache and accentuation of the cardiac sounds; a few months later the albuminuria had completely disappeared.

Such cases are therefore more favourable than the true nephritis cases. In none of them was there mention of the occurrence of oedema.

Remarks.

During the early stage of the war it was necessary to evacuate the cases from France as soon as possible. With greater hospital accommodation, it may now be possible to keep them longer in France, with advantage, for early transport unquestionably sometimes provokes relapse. This, together with more experience in English hospitals, should lead to improved results.

The records permit conclusions other than those expressed statistically. Cases arriving in England ought not to be discharged from hospital until they have been tested by full diet and ward work, with subsequent examination of the urine; they should not be sent to duty till the albuminuria is absent or minimal. Men should not be invalided as permanently unfit until a reasonable time (say, five months) has been allowed for recovery; two attacks during the war should justify invaliding.

Although against instructions, cases with abundant albuminuria are constantly sent to command dépôts, which are ill adapted for such cases. Better results might perhaps be obtained by collecting the cases in special convalescent camps, where their final convalescence and early hardening could be under experienced observation.

SUMMARY.

Approximately 3 per cent. of the cases died, 18 per cent. were invalided during the first period of home treatment, 12 per cent. were invalided after return to duty, 63 per cent. showed no further nephritic history. Men over 40 years old did badly; 71 cases proceeded again overseas.

My acknowledgements are due to Dr. Matthew Young, of the Medical Research Committee, for his help in the collection and collation of the records.

INVALID RATIONS.

BY

EDMUND I. SPRIGGS, M.D.LOND., F.R.C.P.LOND.,

SENIOR PHYSICIAN, DUFF HOUSE, BANFF; LATE SENIOR ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL.

MEDICAL men have been placed in much difficulty of late in the matter of giving certificates to invalids for special rations, and the issue of definite instructions by the Ministry of Food (Regulation M.G.R.M. 27) will be welcomed by them as well as by Food Control Committees.

Diabetes and Tuberculosis.

The regulations allow a greatly increased ration to two large classes—namely, sufferers from diabetes and tuberculosis.

500 MEDICAL JOURNAL 4, 1910

The term "diabetes" may be taken in this connexion to include all subjects of persistent glycosuria who are in need of special diet. They are allowed a maximum of 2½ lb. of butcher's meat, 1 lb. of bacon, and 1½ lb. of butter or margarine weekly. These quantities are intended for a large number of cases of mild diabetes or glycosuria who are able to keep well and active by simple restriction of, or abstinence from, carbohydrate food, and who require to make up their intake of energy entirely, or almost entirely, from protein and fat. The ration is not, of course, suitable for patients suffering from acute diabetes with acidosis. For them such quantities would be excessive and harmful. Indeed, the ration alone, without any other foods, gives about 1,500 calories a day, whereas the diabetic who has been made sugar-free and is gradually recovering his tolerance to carbohydrate, fat, and protein often does not take much more than 1,500 calories of total food for a considerable period.

In tuberculosis a maximum of 2½ lb. of meat, 1 lb. of bacon, and 1 lb. of butter is allowed weekly, giving roughly 1,300 calories a day from these foods. It is common knowledge that a good allowance of protein and fat is of great value in helping the tuberculous subject to keep thoroughly well nourished, and that by thus maintaining nutrition and avoiding overfatigue, the infective process may be prevented indefinitely from advancing or from recurring, as the case may be.

The medical grounds, therefore, for making special regulations for the subjects of diabetes and tuberculosis are obvious, and there can be no doubt that the people of this country will desire that they, like other sick folk, shall receive the diets suited to their complaints. On administrative grounds it is convenient to separate them because they are so many. On national grounds also their special treatment is justified, because there are great numbers of glycosurics and of those who are or have been tuberculous, who are doing a good day's work, and not a few who are carrying out duties of more than usual value to their fellow men. The disablement of such a large body of home workers from a lack of the special food they need would be an unnecessary loss to the country at this time.

Lactation and Pregnancy.

The nursing mother is allowed an extra quantity of meat and fat indirectly, as, soon after the baby is registered, she is able to draw for it a child's ration, which she should consume herself. She is also entitled to a preferential allotment of a pint and a half of milk daily until the child is 18 months old. These allowances will cover the 500 to 1,000 calories which the infant may receive from the breast. Indeed, in most cases there will be a good margin in the mother's favour.

During pregnancy such large additions of food are not required, as though both the growth of the infant and the laying up by the mother of a store of fat for lactation have to be provided for, yet the daily addition of tissue is but small. A pint of milk extra a day in the last three months is allowed in addition to the ordinary diet.

Other Invalids.

If extra food is required by any other classes of invalid except those who are the subjects of diabetes, tuberculosis, and one or two rare complaints mentioned below, it should be supplied in the form of milk, for which a priority ticket may be issued by Food Control Committees on a medical certificate; or in the form of non-rationed foods. Most of the articles of food, besides milk, which are important in cooking for the sick, such as eggs, fish, arrowroot, rice, and flour, are not rationed.

Acute Illnesses.

A broad survey of those invalids whose diet requires special regulation shows that the greater number are suffering from temporary acute or subacute illnesses, including febrile affections of all kinds. Of these a large proportion take less food than ordinary folk and many cannot take solids at all. For all who need it extra milk may be obtained.

Beef-tea.

The beef-tea which in years gone by was used in large quantity for the sick cannot now be made, and medical men should be especially careful not to order it. Our profession has long been explaining to the public that

beef-tea does not possess the food value with which it has been credited for generations. At the present time it is especially wasteful, as it uses up good meat, the food value of which can be utilized fully when it is cooked and eaten by others. The real use of beef-tea is not to feed the sick, but to comfort, satisfy, and stimulate them. Its place may be taken by a mixture of meat extracts with boiling water, or with barley or rice water, to which food value may be added in the form of dried milk.

Neurasthenia.

Neurasthenia, in its many forms, is commonly treated by a liberal diet, containing a large proportion of protein and fat. But it would have been impracticable to allow extra rations for that complaint, as there is no possible limit to the number of claims that might have been made. For the severer cases, which are comparatively uncommon, a sufficiently nourishing diet can be obtained from non-rationed foods, particularly fish and eggs.

Malnutrition.

There appears to be greater hardship in withholding extra rations from cases of severe malnutrition following acute or chronic illness. Some of these patients would undoubtedly make good use of a larger allowance of meat and fat. It would, however, be difficult to draw up a definition which would include them and them only, and there is no reason why, with the help of fish, eggs, and an extra allowance of milk, they should not receive all the food they need. The cereal foods, which are not rationed at present, are plentiful, and will remain the most important source of energy in their diet. It must be remembered also that probably the greater number of such cases will be found in hospitals. In the military hospitals more meat is available. In civilian hospitals the fixed ration of meat and fat is drawn for each patient, but, as those who are acutely ill do not need so much, more is available for the convalescent.

Indigestion.

The numerous sufferers from indigestion do not, as a rule, require extra food, rather the reverse. There is, however, one form of indigestion—the hyperacid form—which is benefited by a diet containing a higher proportion than usual of protein and fat. A free use must be made in such cases of eggs and fish, whilst those who are able to take olive oil, in a dose of an ounce before a meal three times a day, will receive benefit and incidentally a food value of nearly 800 calories. Milk is often badly borne by such patients. These remarks refer only to hyperacidity as ascertained by analysis of the gastric juice. The diagnosis made from symptoms alone is often mistaken.

Chronic Diseases.

There is a large class of chronic diseases, such as gout, colitis, and diseases of the heart, liver, and kidneys, which require adjustment of the diet, but not as a rule any increase of meat and fat. In rickets plentiful fat is beneficial, and has even been thought to be specific; it can be supplied in good milk, or as olive oil, cod-liver oil, or any medicinal preparation of fat that can be obtained. In scurvy, as in other cases of deficiency of vitamins, it is a suitable variety of diet that is needed, and not necessarily any increase of quantity.

Rare Diseases.

Special rations will be allowed for certain diseases, such as coeliac disease, pancreatic insufficiency and sprue. All these are of such rarity that there are many medical men who have never seen a case.

Coeliac disease is a disorder of childhood, arising usually at the age of 2 to 3 years. The symptoms are chronic diarrhoea with large pale motions, weakness and sometimes tetany. There may be deficient absorption of fat. It is treated by giving a diet of ½ lb. to 1 lb. of raw minced meat daily.

The term "pancreatic insufficiency" is used in two senses. It is sometimes applied to cases showing no gross disturbance of the absorption of food in which mild pancreatitis or early diabetes is diagnosed from the occurrence of sugar in the urine or from more complex examinations of the urine and faeces. Such as these, unless they come into the diabetic class, do not require extra rations.

Genuine pancreatic insufficiency comprises cases in which, owing to inflammation or disease of the pancreas or obstruction of its duct, the pancreatic juice is in good part or entirely absent from the intestine. In such cases the digestion of fat is greatly interfered with, as is that of protein, and in some the assimilation of carbohydrate is also impaired. Much of the food is then wasted and extra food has to be given, especially meat, if nutrition is to be maintained.

Sprue is somewhat commoner than either of the above, but it is not every case of sprue which needs a special allowance. There are, however, cases which improve wonderfully on a diet of meat alone, and are able to take large quantities, more than 2 lb. a day, with relish.

In such cases as these, and doubtless in others in which sound reason can be given, the ration may be varied on detailed application being made to the Food Control Committee, who will communicate with the Medical Section of the Ministry of Food.

Sugar: White Flour.

Extra sugar will only be allowed in severe cases, such as are fed by tube. Applications for white flour should be reduced to the minimum, since it has been shown that war bread, when properly baked and chewed, is as digestible as white bread, though it may not be so palatable.

Restricted Tastes.

The doctor's chief difficulty is not with the sick. It is with those, not obviously ill, who assume that the food to which they are accustomed is the food that is necessary for their health, and appeal to him to support this view by a certificate. Many people have grown up in the belief that their digestion is peculiar. Occasionally that is true, but nearly always it is not. Every one of experience will agree that genuine idiosyncrasies are among the rarities of medicine. The thoughtless indulgence of parents is sometimes to blame for restricted tastes; but whatever the cause may be all doctors know what a handicap to the individual such special dislikes are in illness; and at the present time they prove most inconvenient to their owners. No one would pretend that the foods now available are what we would prefer either in health or sickness, and those who feel the change most will have general sympathy; nevertheless, it is the duty of the medical man to explain to such applicants that their condition is not one for the treatment of which it is justifiable to ask for a larger share of the national store.

Conclusion.

For those who are really ill it will often be necessary to draw up a diet scheme in some respects different from that which would have been drawn up in former days. But, with the allowances made by the Food Controller, it is possible to secure that invalids of all classes shall receive suitable food, and enough of it for their needs.

A CASE OF PROMPT RECOVERY AFTER NERVE SUTURE.

BY

JOHN W. HEEKES, M.B., B.S.LOND.,

EX-CAPTAIN R.A.M.C.,

SURGEON SPECIALIST, MILITARY HOSPITAL, BELMONT.

My reason for recording this case is that I do not know and have not read of so early a recovery of practically all functions in a severed nerve after operation. When a nerve is bound up in scar tissue, or has simply been bruised, operation to rectify this condition is usually at once successful, but not if the nerve is severed, except after a long period.

Sergt.-Major —, a German, aged 26, wounded left elbow, in France, June 22nd, 1917; the internal condyle of the humerus and part of the olecranon process of the ulnar were smashed. On August 3rd operation for septic condition of the wound was performed, and some sequestra removed; x-ray examination showed fracture of the internal condyle and olecranon process, and three foreign bodies in the forearm. On November 23rd I removed one foreign body from the front of the elbow-joint. The wound gradually healed, leaving a triradiate scar on the inner side of the joint.

Sensation was lost over the cutaneous distribution of the ulnar nerve in the hand, both front and back. He could not flex his little finger, and only very slightly the ring finger. He had a trophic sore over the dorsum of the little finger. There was no doubt that the ulnar nerve distribution was almost completely paralysed.

Operation.

On January 24th, 1918, an incision was made over the inner side of the elbow-joint. The ulnar nerve, exposed above and below the joint, was found to be severed in the region of the internal condyle of the humerus. The proximal and distal portions were dissected, found slightly bulbous, with some intervening scar tissue between the two ends. The upper and lower segments of the main trunk were electrically stimulated. Some slight response was seen on stimulating the lower segment, and a very feeble response on stimulating the upper segment. The severed ends were cut off transversely as level as possible, and brought together with fine catgut sutures, and the junction surrounded with Cargile membrane. Exact apposition of the cut ends was aimed at.

After-History.

January 27th, 1918. The patient could feel very slightly on the fourth and fifth fingers.

January 30th. The wound had healed by first intention. Sensation had increased over the whole of the ulnar distribution. To my intense surprise the patient on being asked to flex his little finger and his fourth finger did so quite well.

February 27th. Sensation had completely returned over the whole area formerly insensitive. His grip grew stronger every day. He could hold a book or a weight quite well, and even use a hammer. The only defect present four weeks after operation was a feebleness in the action of the third and fourth dorsal interossei muscles. All this, notwithstanding the fact that his wound was formerly septic, and though now perfectly healed, he still has two small foreign bodies in his forearm.

We are told that, according to the theory of Wallerian degeneration, a nerve severed completely degenerates in its whole distal portion. Again, there is ample evidence that regeneration does occur when the cut ends are joined by fibres growing down from the proximal end. In this case there was no doubt whatever that section of the nerve had taken place at the time of injury by the bullet, yet the fact that there was some response in the distal portion when electrically stimulated may be accounted for, because probably some nerve fibres were present in the $1\frac{1}{2}$ in. of scar tissue between the two separated ends of the nerve. Most recent writers on nerve injuries—for example, Sir Purves Stewart and Mr. Evans—say that regeneration seldom takes place in less than three months, and that it is often eighteen or twenty-four months; that sensation returns first and motor function some time after, the earliest known recovery of sensation alone being ten days. Moreover, after considerable septic infection results are longer delayed.

Professor Waller, to whom I wrote, has kindly sent me a few lines on the case. He says that "in those few cases of prompt recovery which have been recorded no satisfactory explanation has been offered. I am inclined to think that prompt recovery may be due to the stirring up by the operation itself of recurrent sensory fibres belonging to other nerves that may form part of the peripheral distribution, and may have had their action in abeyance during complete paralysis before operation. Increased knowledge in the present day of the extensive halo of functional disturbance aroused by an organic focus of real injury would lead me to be on the watch for the possibility of prompt reappearance of sensation, by the cerebral suggestion as well as by the peripheral excitation afforded by the operation itself. I am at the present moment engaged in measuring the 'emotivity' of shock and other cases, and it would be useful to know if your patient was of high or low emotivity."

As far as one can judge clinically this patient is of low emotivity.

I am indebted to Dr. Charles Corben for assisting at the operation, and to Lieut.-Colonel Guthrie, R.A.M.C., for permission to publish the case.

THE Carnegie United Kingdom Trust has published a most elaborate report on public baths and wash-houses, prepared for the trustees by Miss Agnes Campbell, B.A. The report sets out with lavish detail the present provision of baths and wash-houses throughout the United Kingdom, the use made of the facilities provided, the finance of such undertakings, and a discussion of the factors which bear upon the subject generally. Without wishing to minimize the value of such an exhaustive investigation, the question occurs to us whether, in the present situation, with an extreme scarcity of paper, the publication of a monograph weighing 2½ lb. is expedient.

A SPECIAL CRUTCH FOR MEN WHO HAVE LOST BOTH AN ARM AND A LEG.

BY
R. LANE JOYNT, LIEUT.-COLONEL R.A.M.C.,
DUBLIN.

THE accompanying illustrations show a crutch designed by me for a man who has suffered a double amputation (Figs. 1 and 2). He has lost the left leg below the knee, and the left arm at the surgical neck of the humerus, so that there is no axilla capable of bearing weight on that side. The appliance enables a man so disabled to move about either while he is waiting to have an artificial leg fitted or when he is tired of using the new leg.

FIG. 1.—Crutch for loss of left leg and left arm: the patient standing beside it.

FIG. 2.—The patient using the crutch.

The appliance consists of two crutches of the bifurcated type morticed into one axillary piece in the form of the letter A. The crutch, on the side on which the leg is lost, slopes more than that on the sound side and its timbers are morticed inside the latter (Fig. 3). Cross-bars of wood complete the horizontal part of the letter A, but project to the outer side of the more sloping crutch to form, with a curved aluminium plate, a shelf on which the man places his flexed leg stump. The two crutches are braced together above, and a steel wire truss takes up the side strain on the more sloping crutch. A handle is fitted in the usual place on the sound side. The legs of the crutch are two feet apart at their base.

In use the man places his stump on the shelf and swings

his sound leg between the crutch legs. No weight need be borne on the axilla of the sound side.

The total height of the appliance should be at least two inches less than that of ordinary crutches intended for a man of the same height. This is necessary to enable the man, by fully straightening his sound leg, to lift the crutch forward clear of the ground. A man with only one hand can stand on the appliance and remove his hand from the handle to open a door, or use his hand for other purposes. If the patient has lost an arm on the opposite side to the leg, the handle is placed outside the stump shelf, the axillary piece of the crutch being on the armless side, not necessarily carrying any weight.

Both types are being used in the Duke of Connaught's Hospital for Limbless Soldiers at Bray, co. Wicklow, for

FIG. 3.—Crutch for loss of left leg and either arm.

FIG. 4.—Extemporized crutch for loss of left leg and either arm.

double amputations as well as for cases of crutch paralysis.

For emergency work the appliance may be rapidly constructed, as shown in Fig. 4, by lashing together two strong bifurcated crutches with the head of one crutch below the other; a few pieces of timber lashed crosswise serve to brace them firmly and by their projecting ends to form the shelf. Vertical pieces of timber lashed from the shelf to the foot of the more sloping crutch relieve the side strain.

It is made by Messrs. Smith and Sheppard, of St. Stephen's Green, Dublin, in its various forms, and the following measurements should be given: Height from sound axilla to ground, height from sound axilla to middle of sound hand, height from perineum to ground, and state which arm and leg are lost.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TOXIC JAUNDICE: ATROPHY OF LIVER: REGENERATION AND RECOVERY.

THE observations of Dr. Crawford (p. 450) on the recuperation of the liver tissue after an attack of toxic jaundice caused by the action of T.N.T., agree closely with those which I have been able to gather at another big filling factory.

Of the number of cases reported since notification came into force we have 33 still remaining at work with us. Ten of these were notified erroneously and there is doubt as to the nature of a further three; but the remaining twenty were apparently cases of true toxic jaundice. I have made a full examination of all these within the last six weeks. I am not able to say in every case to what extent the area of liver dullness was diminished during the attack, as in the early days of the factory the patients were allowed to go to their own homes about the country for treatment; but when I made this examination, from six to eighteen months after their return to work, the fact was marked that they did not show diminution in the area of liver dullness nor interference with nutrition or the digestive functions.

The most noticeable thing about some of the cases is that though the liver seems to have recovered they show signs of deterioration of heart muscle, with inability to undergo sustained exertion, and general signs of heart distress—in fact, they present the same picture as those workers who have suffered from severe toxæmia without jaundice, and my experience here is that those workers who recover from toxic jaundice do not afterwards suffer from damage to the liver function so much as they do from degeneration of heart muscle. I feel that the toxæmia is the general affection, and that jaundice is an accidental symptom in certain cases, determined by some at present unknown cause in certain of the victims of toxæmia. One very general feature is the complaint for the first few months after convalescence of pain in the right side, either over the liver area—front or back—or in the abdomen just to the right of the umbilicus.

I note with interest Dr. Crawford's statement that in her cases the motions were not completely bile-free; this, to my mind, should be a common sign in toxic jaundice, owing to the fact that some of the liver tissue is operative, and that the bile ducts are not occluded. My experiences also coincide with Dr. Crawford's statement that cyanosis is not a necessary antecedent to toxic jaundice, many cases showing no signs of it when the first trace of yellow showed in the sclerotics.

Chilwell, Notts.

W. BOWER, M.A., M.B., B.O.

A WAX THERMOMETER PRIMARILY DESIGNED FOR USE IN HOT-AIR STERILIZING CHAMBERS.

THE thermometer here shown is intended to be introduced with each batch of clothing. It consists of a metal frame provided with two sets of spring clips, into which fit two glass bulbs—large vaccine ampoules do admirably—the one containing wax melting at the minimum temperature adopted for sterilization, the other wax melting at a temperature beyond which it would be dangerous to expose clothing. In each bulb are a few small black glass beads.

The bulbs are placed in position beads uppermost, and after use, when the wax has rehardened, are slipped out and put back again with the beads at the top end.

Since at the required temperature the wax in the bulb takes ten minutes to melt, the deposition of the beads at the bottom of the bulb indicates, for instance, in the case of the minimum bulb, that this temperature has been reached and maintained for, at any rate, this length of time.

In order to ascertain what reliance might be placed upon the sterilizing effect on lice and their eggs of a temperature of 60° C. maintained for ten minutes, experiments were very kindly carried out by Mr. A. Bacot, of the Lister Institute, both upon lice and their eggs exposed in this manner in a hot-air sterilizing chamber in France, and subsequently dispatched to London for the determination of their viability, and upon lice and eggs similarly

From a photograph of the thermometer.

exposed by Mr. Bacot himself. In each instance the experiment proved that an exposure at 60° C. for ten minutes is lethal to lice and their eggs.

With this knowledge, therefore, a wax melting at not less than 60° C. may be adopted for the minimum bulb, and a wax melting at a temperature not higher than 75° C. or 80° C. for the maximum bulb.

This thermometer is, in essence, an adaptation of Bacot's idea of placing dishes containing wax in hot-air sterilizing chambers, and I take this opportunity of expressing my best thanks for the keen interest he has taken in this appliance during the testing of its practicability.

I wish also to express my thanks to the O.C. — Army Wireless Company, R.E., in whose workshop the original model was made; to Captain W. H. Smith, R.F.C., for the excellent photograph; and to Captain Jacobs, R.A.M.C., for opportunities for testing the appliance in the hot-air sterilizing chambers he has designed.

Note.—Care must be taken to ascertain by actual trial in the bulbs if the wax supplied by the makers complies with the indicated melting point. If necessary, suitable adjustments should be made by mixing waxes of different melting points.

E. EMRYS-ROBERTS, M.D.,
Captain R.A.M.C.

FRACTURE OF INTERNAL CONDYLE OF HUMERUS BY MUSCULAR ACTION.

PTE. R., aged 29, jumped from the ss. —, while she was sinking, on to the deck of a rescuing ship. To break his fall he caught a tightly stretched rope with his left hand, and as he gripped it, felt a sudden pain in his "crazy bone." He did not fall, but landed on his feet with his arms above him holding on to the rope, and is quite certain that nothing hit his elbow. The radiograph showed a separation of the internal condyle, undoubtedly due to muscular action of the flexors of the wrist. At the present time, three months after the fracture, the separated

condyle is displaced downwards, firmly adherent to the humerus, and the joint movements are perfect. All the man complains of is a continuous dragging pain at the site of the fracture. The reattached condyle is very tender to touch, evidently due to injury or implication in callus of the ulnar nerve, although there is no anaesthesia below the elbow.

GERALD LAWRENCE,
Captain R.A.M.C.

Reviews.

AMERICAN ADDRESSES.

IN the autumn of 1917 Sir BERKELEY MOYNIHAN gave some addresses to American audiences, and he now publishes them under the not very perspicuous title of *American Addresses*.¹ The dedication is to G. W. Crile, and the preface indicates that they are intended for the use of American colleagues entering upon war conditions from which we have learnt, and unlearned, many things. That three-fourths of the book is a summary, eclectic certainly, of professional war literature, the author candidly acknowledges when he says on the first page, "I have gathered a posie of other men's flowers." The paper called "The Causes of the War" might, indeed, well have been elaborated, for even if he cull others' blooms, Sir Berkeley is skilled in arranging the bouquet; he carries one in fancy to the native soil of the flowers. There is no question here of diplomacy or armaments or murders. It is the elemental question of Auramazda or Ahiriman, freedom or tyranny, voluntary dedication or authoritative subjection.

"That one man," said Glanvill (*The Vanity of Dogmatizing*), "should be able to bind the thoughts of another, and determine them to their particular objects; will be reckoned in the first rank of *Impossibles*: Yet by the power of *advanc'd Imagination* it may very probably be effected." Sir Berkeley is all for imagination; says of it that "it is the scaffold upon which one stands to build the structure of truth," and thinks it is just because the Prussian state has found another means of binding men's thoughts and determining them to its sinister purposes, that we are at war. The German has deliberately perfected a system of education to mould the mind, from the cradle to the grave, into the conviction that expediency backed by power is "right." To none will the moral appeal more forcibly than to American citizens; where a fundamental ideal is at stake, compromise is out of the question; it must be a fight to a finish. American surgeons and, we believe, the whole people of the United States are in the war to see it to that finish.

The second paper, on "Gunshot Wounds and their Treatment," describes the beyilderment amid which aseptic surgery found itself suddenly out of its depth, with the art of swimming nigh forgotten; describes the recovery of old and the development of novel strokes wherewith to ride the flood. The story is well told in a manner adapted to the author's purpose. It seems doubtful if he has made clear enough the essential difference between the use of bipp and similar agents in wounds excised within six or eight hours of receipt, when the function is to inhibit the development of organisms; and their use in wounds not only "contaminated" but already "infected": in which the bacterial strains are already established.

The third study is on the treatment of injuries of peripheral nerves, which was published in full in our columns on November 3rd, 1917. The experience of some surgeons may dispose them to disagree with the author's dictum that "nerve anastomosis is to be sharply condemned." In cases in which a large defect precludes suture, the careful insertion of peripheral and proximal ends within the sheath of a neighbouring trunk has, we understand, been productive of a result that is, to say the least of it, better than none.

Two other papers, on gunshot wounds of the knee-joint, and of the lungs and pleura, give a good general account of the principles upon which more recent methods are based.

MARITAL PHYSIOLOGY.

In a small work entitled *Married Love*,² Dr. MARIE STOPES has endeavoured to meet the need of healthy young people of the educated class for information as to the sexual responsibilities of marriage. Though not a medical woman, the author has special qualifications for this task: with high scientific attainments she combines literary skill, sympathetic insight, idealism, and more than common courage. As Dr. Jessie Murray points out in a short preface, this aspect of sex relationship has usually been looked on as too sacred or too dangerous for entirely frank treatment; but the modern view is that reticence has been carried so far as to defeat its purpose; everything depends on how the matter is presented. To the married and to those about to marry, provided they are normal in mind and body and not afraid of facing facts, this should prove a most helpful book. It is more than a physiological treatise on the Tree of Knowledge, written from the woman's point of view in popular language; sexual aberrations beloved of German writers and their English and American imitators are left alone. Notwithstanding the vast output of books on sex in recent times, Dr. Stopes has, we think, proved that something remained to be said on this subject if the right person could be found to say it in the right way.

As part of her main argument she sets out a view of the periodicity of sexual desire in women with a degree of precision not hitherto attempted. It is not exactly new, for the idea of periodicity was much canvassed during the discussion of the relation, if any, of menstruation to oestrus some years ago, and in general literature is the undertone of Tolstoi's terrible little book *The Kreutzer Sonata*. Dr. Stopes expresses her intention to publish in scientific form and at greater length the results of her observations. This seems desirable, as the text fails to carry the assurance that the generalization rests on more than a relatively small number of cases, confined to a particular social class. In the meanwhile we may say that the outline as presented to a lay audience tends to explain much that has puzzled students of feminine psychology, and offers a way of married happiness that may prove very helpful to many couples.

Concerning the book as a whole we feel with Professor Starling, whose letter is included in its preface, that such guidance is necessary, since "instinct in man is all insufficient to determine social behaviour, and there is need of instruction in the highest of physiological functions, that of reproduction, as there is in the lower functions of eating and drinking." We therefore commend it to medical men and women, and through them to those of the general public who in their judgement are likely to profit by its teaching.

THE HISTORY OF THE ARMY MEDICAL SERVICE.

THE *Roll of the Army Medical Service*³ makes a fine appearance, and is a worthy memorial of the ability, patience, and accuracy of the late Colonel WILLIAM JOHNSTON; it is, indeed, only what would have been expected by those who knew the man and his work. Owing to the industry and care of Colonel Johnston we now have an accurate biographical record of the Army Medical Service from the beginning of the reign of George II to the year 1898, and those of us who have experienced the difficulty of a search in the Public Record Office and the British Museum will appreciate the load taken off the shoulders of future inquirers by the publication of this book. As a work of reference this book will rank with Munk's *Roll of the Royal College of Physicians* and Crawford's *History of the Indian Medical Service*, and we could wish that someone would undertake a similar work with reference to the Naval Medical Service. No book of this kind can claim infallibility, but after applying several severe tests we have not found any considerable errors. It was fortunate that Colonel Howell could find time to edit the book, and we do not doubt his

well-known expert knowledge of military medical history has contributed to its value.

The development of the Army Medical Service can only be understood by a careful study of its history, and we had hoped that the introduction would have dealt fully with that subject. But in our judgement the history given there of the development of the service is inadequate in length, and, further, is not very clearly written. Forty pages only are devoted to a consideration of this large and important subject, which is worthy of a more extended survey. This is to be regretted, for the famous Fifth Report of the Commissioners for Military Enquiry, published in 1808, contains almost all the information necessary for a complete account of the development of the Army Medical Service down to that date. No doubt space was a consideration, but we should have welcomed a longer account of this part of the subject, especially from the expert pen of Colonel Howell. The report of the Commissioners has indeed been used, but not as fully as it might have been. But however that may be, this valuable and accurate book will find a place in every reference library.

NOTES ON BOOKS.

THE second edition of Dr. PENHALLOW's book on *Military Surgery*⁴ is a great improvement on the first. That was avowedly written from a base hospital in England. Nowadays much of the surgery that really matters to the patient is done at the casualty clearing station. Of course much remains to be done at the base, but the tendency is to do more and more nearer and nearer the front, because if good surgery be done there, there is less and less to be done afterwards. To deserve its title such a book must deal with the first treatment of fresh wounds and injuries, and to a great extent the author has now done this, partly no doubt as a result of what he has seen himself, but largely by analysis of published papers, and of these he gives a very useful bibliography. For the next edition Dr. Penhallow will have still more ample records of the latest developments in primary treatment, and will be able to make room for his account of them by omitting the present case notes, which are out of place in a work of this size.

The volume *A Complete System of Nursing*,⁵ by A. MILLICENT ASHDOWN, fairly deserves its name. It is founded upon a book by the late Miss Honour Merten, but has been thoroughly revised and greatly improved. Chapters on general nursing duties and on general observation of symptoms are followed by others on special departments of medicine and surgery. The section on the preparation of the room for an operation contains a useful enumeration of the various things a nurse must do and prepare. In the various chapters instructions are given for preparing a patient for examination as well as for operation, and this is a valuable feature. There is a chapter on ophthalmic nursing, and others on gynaecological and obstetrical nursing. The book certainly seems to tell everything a nurse can learn from print. Its fault is that in some places, especially in the remarks on treatment, it attempts too much. The description of splints in such a book cannot be complete, and it is just possible that an inexperienced nurse may consider that a case treated by any other splint than those illustrated—and some of them are a little antiquated—has not been properly treated. A warning to this effect might properly have been given in the preface.

The Happy Warrior, and Other Poems,⁶ by Mr. AUGUSTUS COOK, is one of the many small volumes of verse called out by the war. Its author feels keenly the many emotions called up by battle, by the contrasts of war, by the work of women in the present times of stress, and by the part played by medical science in the relief of war's havoc. His verse shows this feeling expressed with sentiment and a clear sense of form; it should give satisfaction to many who, with similar feelings, are less happily able to give them expression.

SATURDAY, MAY 4TH, 1918.

BOTULISM.

THE occurrence of a certain number of cases, the circumstances and symptoms of which recall the description of a form of food poisoning described by van Ermengem in 1895 under the name "botulism," makes it convenient to give a short account of that disease. Though he gave the name *B. botulinus* to it (*botulus*, a sausage), van Ermengem first cultivated the bacillus from a pickled ham which was not decomposed in the ordinary sense. The symptoms in these cases are stated by Muir and Ritchie¹ to correspond closely with those occurring in the so-called sausage poisoning met with in Germany and other countries where sausages and ham are eaten in an imperfectly cooked condition. The cases form a well-defined group, the symptoms of which are chiefly referable to the action of a toxin on the medulla. They include more or less marked disorder of the secretions of the mouth and nose, and internal and also external ophthalmoplegia, especially dilated pupils and ptosis—the last being apparently a very striking symptom—dysphagia, sometimes complete loss of power of swallowing, and loss of voice. Constipation is the rule, and retention of urine common. In fatal cases death is due to interference with the cardiac and respiratory centres. It is stated that there is no fever and no disturbance of the intellectual faculties, but apparently drowsiness may be a marked feature. The symptoms do not come on earlier than twelve to twenty-four hours after ingestion of the infected food.

The bacillus can be cultivated on ordinary media—best, it is said, with added grape sugar—but only under strictly anaërobic conditions. Kempner has obtained it from the intestine of the pig. The bacillus produces a very potent toxin, and the symptoms in the human subject are believed to be due to the absorption of this toxin from the alimentary canal, for it is only after or immediately before death that a few bacilli may enter the tissues. It is stated that some cases have occurred after the consumption of fish and vegetables. Marinesco and other observers who have examined the nerve cells in experimental poisoning with the botulinus toxin agree as to the occurrence of marked degenerative changes, especially in the motor cells of the spinal cord and medulla. Necropsies in man have generally shown hyperaemia of most of the organs, especially of the meninges, lungs, liver, and kidneys, due to the cardiac weakness and dyspnoea occurring at the end of the disease. Microscopically the ganglion cells in the pons, medulla and corpora quadrigemina have shown chromatolytic changes, disappearance of Nissl's granules, displacement, and cloudiness of the nucleus, and finally complete destruction of the cell. In a recent lecture on the subject Dorendorf,² one of the medical consultants to the German army, states that while epidemics of botulism are rare, even in Germany, isolated examples or small groups of cases are not infrequent in that country. Often many of the

persons who have consumed the infected food escape, owing to the fact that only certain parts of the food have been permeated by the bacillus or its toxins. In the course of three months Dorendorf saw 7 cases in a military hospital in the east of Germany; 5 were sporadic, and 2 had contracted their illness from the same source.

Diagnosis is rendered difficult by the fact that in this form of food poisoning the gastro-intestinal phenomena are of secondary importance. The first symptoms, namely, nausea and a feeling of weight or actual pain in the gastric region, may occur, according to Dorendorf, either directly or a few hours after consumption of the tainted food. In almost all cases there is vomiting, which is usually repeated. As a rule the patient complains at an early stage of giddiness, which prevents him from walking or even standing. After twenty-four hours at the earliest, more frequently after two or three days, paralysis develops and dominates the scene. In Dorendorf's cases the sixth nerve and the branch of the third nerve to the levator palpebrae were most affected, and paresis of the pharynx and oesophagus were frequent in severe cases. Palatal palsy was also common; facial and hypoglossal palsies were less frequent. Paralysis of the larynx was present in half of Dorendorf's cases, and as paralysis of the abductors occurs rapidly, regular laryngoscopic examination is indicated in order to perform tracheotomy in cases of bilateral abductor paralysis, the danger of which is increased by the presence of ulcers on the laryngeal mucosa. Paresis of the stomach and intestine is manifested by the feeling of weight after food and obstinate constipation. Even mild cases may complain of difficulty in micturition owing to involvement of the detrusor vesicae. Paralysis of the sphincter is frequent. Disturbances of taste and smell were not observed in Dorendorf's cases, but two of them complained of tinnitus. The extremities were not affected in his cases, but Burger has noted paresis of the lower limbs and loss of the knee-jerks. Paralysis of the diaphragm is not uncommon. Considerable tachycardia, indicating vagus paralysis, has frequently been noted before death. Sensory disturbances do not occur, and Dorendorf did not observe any disturbance of consciousness. Somnolence was observed only in the severest cases; it passed into coma. The temperature was not raised unless complications developed, such as deglutition or hypostatic pneumonia, parotitis, or inflammation of the upper respiratory and digestive tracts. The dryness of the upper respiratory and digestive tracts was constant, and in severe cases was the cause of ulcers in the mouth, fauces, and pharynx, epistaxis, and frequently of parotitis. It also contributed to the difficulty in swallowing invariably present. The diagnosis in Dorendorf's cases was made on clinical grounds, and in one case on the strength of the *post-mortem* findings. Attempts to cultivate the *B. botulinus* from the organs failed. It is suggested that in doubtful cases the diagnosis might be established by injection of the patient's serum into guinea-pigs, as subcutaneous injection of the watery extract of infected ham or cultures produces characteristic paralyses of the extremities, intestine, and bladder in these animals. Dorendorf puts the mortality as high as 60 per cent., death being due to paralysis of the respiratory centres, cardiac paralysis, or pneumonia. Even in favourable cases convalescence is slow, and visual disturbance, muscular weakness, and digestive disorders may persist for weeks. Treatment should consist in washing out the stomach thoroughly, for,

¹ *Manual of Bacteriology*, second edition, 1913.

² *Deut. med. Woch.*, xliii, 1531-1534; 1554-1556.

owing to the early onset of gastric paresis, the poisonous article of diet may remain in the stomach for several days after it has been swallowed. Tube feeding will be required for the palatal and pharyngeal paralysis. Thirst should be relieved by rectal or subcutaneous injections of saline.

The toxin corresponds closely, as regards relative instability, conditions of precipitation, and its readiness to combine with the cells of the brain and spinal cord, with the toxins of diphtheria and tetanus; and Kempner has prepared an antitoxin which has a neutralizing property *in vitro* and considerable therapeutic value when given some hours after the toxin in experimental animals. The antitoxin, it is said, is given preferably by intramuscular injection, but it appears to be difficult to make. From some experiments on animals made by Kobs it would appear that the botulinus toxin is rendered innocuous by the addition of diphtheria antitoxin, so that the use of the latter may be justifiable should the specific antitoxin not be obtainable.

With regard to prevention, it may safely be assumed that the thorough cooking of food—not only sausages, but brawn, chitterlings, trotters, ham, and similar articles—would obviate all risk.

THE PROFESSIONS AND THE EXCESS PROFITS DUTY.

In the course of the Budget debate reference was made to the fact that the earnings of professional men were exempt from the excess profits duty, though in the case of the business man the whole of his profits were brought within the scope of the tax without any regard to the fact that in most cases some portion of that total profit was the result of his personal ability and exertion. More than one speaker suggested that this constituted a legitimate grievance which should be redressed by treating professional earnings as liable to duty in precisely the same way as business profits. The suggestion may be plausible, but does not seem likely to be supported by the Chancellor's official advisers if we may judge by the earlier debates dealing with this comparatively new though highly lucrative duty. At the same time it is desirable that any misapprehensions on the subject should be dispersed; we cannot imagine any intelligent observer considering the idea that the medical profession should be still further burdened as other than absurd, but even unintelligent criticism must sometimes be refuted. We are aware that the speakers in question probably had in mind professional accountants, who are said to have received heavy fees in connexion with their work in settlement of liabilities of their clients to the new Government levies, but one member at least referred to doctors as being fit subjects for assessment to the excess profits duty.

It should be remembered that when the duty was first publicly discussed it was popularly called the "war profits" tax—a name which was really more appropriate to the already existing munitions levy on establishments controlled by the Ministry of Munitions—and that misnomer perpetuated the misconception which it epitomized. Broadly regarded, the excess profits duty was intended to be, and is, a special levy on the enhanced profits of capital employed under war conditions. The two special factors operating to give rise to that enhancement are, first, the general and rapid rise in prices which has inflated the profits of practically every manufacturer or trader, not only by giving him a special, if temporary, profit on stocks in hand or bought in advance of need, but

also by providing him with favourable and frequent opportunities for unnecessarily increasing his prices; and second, the extending activities of the Ministry of Munitions, which has widened the circle of profitable war work far beyond the area covered by the munitions levy. From the operation of these causes the medical profession has been entirely free. To take an illustration at random: a drapery establishment in the neighbourhood of a munition factory will probably make substantially increased profits, but the local medical practitioners will remain practically unaffected. And the reason is not far to seek. Such an establishment is an organized machine capable of coping with additional turnover without radical change, but merely with the addition of new staff, or possibly accommodation; but the "turnover" of a medical man is an index of his personal effort, and is not capable of similar extension.

Nor is this all. In dealing with a comparison of pre-war and present commercial profits, regard can be had to the increased rate of exhaustion of the plant and other business assets, which can be approximately measured and allowed for when the tax is computed; but who can express in terms of money the exhaustion of vigour, health, and brain power suffered, where the additional income represents a corresponding—and almost intolerable—drain on physical and mental assets? The exemption of the medical profession from this tax does not rest on any sentimental regard for the sacrifice which its members are making to the common cause both at home and abroad, but on the reasonable application of economic principles. It may be that these same principles would justify an allowance for the personal factor in business profits which the revenue authorities might find it impossible to carry into practice, but that fact should not prevent them from operating wherever their application is practicable.

Lastly, as our readers are no doubt aware, even if these principles were ignored and all medical incomes were closely scrutinized the annual exempt margins allowed over the pre-war standard of profit would prevent the Exchequer from receiving any duty which could be regarded as an equivalent return for the expenditure of time and labour involved in the investigation.

Members of the medical profession are, of course, liable to the super-tax, which now begins at incomes of £2,500 a year instead of £3,000, and is chargeable at higher rates than last year. The lowering of the limit of income subject to the extra tax will probably affect a not inconsiderable number of medical men.

THE MEDICAL SERVICE IN THE ZEEBRUGGE RAID.

THE graphic official narrative of the naval raid on Zeebrugge in the small hours of St. George's Day made no reference to the work of the medical service during the operations. The following short note may give some idea of the work of the surgeons and their staff in the raid. Staff Surgeon McCutcheon, who was in charge of the medical arrangements, had with him three medical officers in the *Vindictive*, the medical staff numbering twenty-nine in all, distributed in four parties. A considerable proportion of the subordinate staff belonged to non-combatant ratings specially trained for the raid, and included two non-combatant officers—a chaplain and an assistant paymaster—who both rendered valuable services. In the *Iris*, which carried the special landing unit of marines, there was one medical officer with a bearer party of sixteen marines, and six men of the sick berth rating. In the *Vindictive* there was also a party of nine stokers and seamen under

the charge of a medical officer, told off for such special duties as might arise. These got on to the Mole and did good work in collecting casualties and transferring them to the ship. Special arrangements had been made in the *Vindictive* for the reception of a large number of wounded, the medical officers and their staff being grouped in three stations—forward, aft, and amidships. Directly the boarding party was landed the port side of the mess deck was converted into a reception place for the wounded, and all available cabins and compartments were cleared for the purpose. More than 170 cases were treated in the *Vindictive*; most of the wounds were multiple and extensive, and there was much severe haemorrhage needing application of the tourniquet. The wounded were eight or nine hours on board, but first aid was all that was possible in most cases; this included the administration of morphine and saline injections, and the application of temporary dressings. Darkness and the artificial fog added much to the difficulties of collecting and transferring wounded on board ship. The Medical Department R.N. received notice that the attack had been made, and when the first batch of casualties was landed at the base in the morning naval ambulance trains were awaiting them at the ship's side. They were rapidly dispatched to various naval hospitals, and the last contingent of patients was comfortably settled in hospital by 6 p.m. The bulk of the wounded were sent to the Royal Naval Hospital at Chatham, where they were visited on April 30th by the King and Queen, who expressed high appreciation of the medical arrangements. Although there were a number of casualties among the stretcher-bearers of the Marine and special units, no medical officer received any injury.

CARE OF THE BLIND SOLDIER IN GERMANY.

THE German War Office has accepted a reduction of vision to $\frac{1}{5}$ as a definition of blindness. A rough estimate of the number of soldiers in Germany coming within this definition by the spring of 1917 was 2,000. The estimated number of the blind before the war was 40,000, so that the magnitude of the problem has not been very greatly increased, but some of the conditions have been altered. For example, before the war only 0.2 per cent. of the blind—that is, only 75 to 80—had had a university education, but among the soldiers blinded in the present war from 10 to 15 per cent. according to one estimate, and as many as 20 per cent. according to another, have received higher education. In order to discuss the problems thus raised, Professor Bielschowsky, in December, 1916, called a conference in Leipzig. The facilities in existence for the education of this minority were very inadequate. The central library for the blind in Hamburg, founded in 1900, had, indeed, by 1915 lent out 20,000 books, but it possessed practically no works in Greek, Latin, or Hebrew, nor any scientific works. The conference appointed a commission of six members to inquire into these and kindred matters; it also undertook to make a selection of standard works on various subjects, including the sciences, suitable for blind script. German and Austrian authorities in the various faculties appear to have settled this matter satisfactorily. Marburg has been selected as the centre for the blind of the educated classes on account of its central position in Germany, its university, the absence of crowded street traffic, and its facilities for cheap living. In the first academic term of 1917, this institution, which is only a few minutes' walk from the university, received seventeen pupils, whose education was undertaken by three blind university teachers. It has been calculated that the thirty-three schools and forty-three workshops already in existence will be capable of absorbing the blind soldiers of the uneducated classes. Private enterprise is to be discouraged, as homes for the blind soldier conducted at the expense of independent persons have been found to pamper instead of teach, and to be unnecessarily costly. The blind are kept in military hospitals till medical treatment is no

longer necessary. They are then transferred for three months, still under army control, to schools for convalescents. The pension for the blind private is from 1,300 to 1,400 marks, and if he chooses to prolong his residence in the school he may do so at a charge of one mark a day. Massage as a means of livelihood for the blind has proved disappointing, as the German is said to distrust the blind masseur. As a rule one year is required to teach blind script and a simple handicraft such as basket-making. Many blind soldiers have returned to their former work—to baking, cigar-making, shoe-making, and even watch-making. About 20 per cent. of the blind soldiers were agricultural labourers; their return to work on the land has been successfully effected in many cases. Schemes have been formulated for diluting blind labour, but the aid of companions with good sight is a doubtful gain; the blind who are well equipped in body and mind are better served by the independence which a thorough education in a school for the blind offers. The training of dogs as leaders of the blind has also been taken up.¹

AORTIC REFLUX DUE TO SHELL EXPLOSION.

THREE cases of traumatic aortic regurgitation in soldiers previously healthy, and especially free from evidence of syphilis or rheumatism, and noticed after having been blown up by shell or grenade explosions, have recently been reported. Usually in traumatic rupture of a cardiac valve there is sudden onset of severe distress, but in Cramer's² case, and in one of the two reported by Brossard and Heitz,³ the symptoms did not supervene until eight and three days after the explosion. In these two cases the soldiers were blown up and fell on their backs, and the traumatic rupture is ascribable to this injury; whereas in the third case, reported by Brossard and Heitz, in which there was in addition immediate and severe nervous shell shock, the explanation adopted is that the sudden alteration in the atmospheric pressure produced by the explosion damaged the nervous system and at the same time ruptured the aortic valves. The sudden alteration of pressure caused by explosions has been known to rupture the lungs without external injury (Sencert), to cause haemorrhage into the central nervous system, and haematuria, and it seems reasonable to believe that similarly the aortic valves, which according to Barié are the most delicate of the cardiac valves, might thus be ruptured.

TREATMENT OF GONORRHOEA IN ANTIQUITY.

ALEX RENAUD in a recent Paris thesis gives some details of the ideas which prevailed as to the nature of gonorrhoea in the early days of medicine. Hippocrates, in the fifth century before Christ, believed that purulent discharge from the urethra depended on carnosities in the canal; Galen, in the second century of the Christian era, held that it was an involuntary emission of semen—hence the name "gonorrhoea" by which he called it. This was also the teaching of Coelius Aurelianus in the sixth century, and of Bernard Gordon in the thirteenth. In the ninth century the Arab physician Rhazes recommended an antiphlogistic therapy together with injections of honey water with decoction of quince seeds. To cicatrize the canal he injected white lead or antimony. Gordon advised bleeding, emesis, and red cerate. For retention he prescribed water baths, combined with the application of living or crushed bugs to the penis. In this he may have imitated the practice of Avicenna, who, to excite the flow of urine, introduced a louse into the patient's urethra. In the eleventh century Constantine the African recommended injections of woman's milk. In the fifteenth century Marcellus Cumanus used cow's, goat's, or woman's milk in the same way, with purging, diet and oil inunctions as adjuvants. As a preventive measure the school of

³ J. Brossard et J. Heitz: *Ibid.*, 71–74.

Salerno recommended micturition immediately after coitus. In the thirteenth century William, of Salicet advised washing out with water after suspicious intercourse, and his pupil Lanfranc used ablutions with equal parts of water and vinegar to which the patient's urine was sometimes added. John of Gaddesden is credited with the invention of the suspensory bandage; at the end of the fourteenth century the same device was used by Guy de Chauliac. For the treatment of the discharge he used injections of oil of scorpions or pigeon's droppings diluted in lye and strained. Like Avicenna and Gordon, he believed in the efficacy of lice and bugs applied to the meatus.

THE PREVENTION OF SUICIDE.

THE Registrar-General for England and Wales in his report for 1915 recorded a remarkable diminution in the number of male suicides. The rate per million living, which was 157 in the decennium ending 1910, and 151 in 1914, fell to 104 in 1915. In 1916 there was a slight rise, the rate being 111. Taking the group of males between 15 and 45, the mortality, which had fallen from 145 per million in 1914 to 102 in 1915, rose again in 1916 to 117. The rate for women also shows a fall, but the numbers are much smaller; the rate was 47 in the decennium ending 1910, 45 in 1914 and 1915, and 38 in 1916. The only age at which male suicides do not greatly outnumber female is 15 to 20, when the two sexes were in normal times about equal, but in the war years the number of female suicides was higher than that of males; this is to be accounted for by the diminution of the civilian male population. Among women the suicide rate at ages 20 to 55 showed a marked reduction on the 1901-1910 standard. Dr. Stevenson points out that it is noteworthy that this change should have accompanied such a period of stress as the women of the country passed through in 1916, and adds that it does not suggest that their moral has been in any way injured by their widespread employment upon work hitherto thought suitable only for men. For women beyond the working age the suicide rate has not fallen, whereas in the male sex the greatest reduction has occurred at the ages 45 to 65. The experience in both sexes seems to point to employment as an effective preventive of suicide, for except that there may have been possibly some increase of household duties, owing to the absence of younger members of the family, women over 55 have probably had little additional work thrown upon them, whereas there has been increased employment of men even at the higher ages. The fact that the reduction set in first and has been carried furthest in the male sex harmonizes with this hypothesis, for increase of employment began earlier for men than for women, and the demand for male labour has remained in excess of that for female. It is suggested that increased employment would operate in at least two ways: in the first place, it would provide an interest in life calculated to divert the mind from personal worries, and in the second place the opportunity of useful work at a living wage would suggest an alternative to suicide in cases in which loss of capital or of employment would otherwise lead to despair. The decrease in alcoholism may also have contributed to the general reduction in suicides, but it would not explain the change in age and sex distribution. It should be added that cases of attempted suicide coming to the knowledge of the police declined to an even greater extent than deaths from suicide. The frequency of suicide among men in military employment increased regularly with age, as amongst civilians; as the men were all subject to military conditions, which are similar for all, the progressive increase in mortality must be attributed to increasing innate tendency to suicide as age advances rather than to increasing difficulty of circumstances, to which it might in the light of purely civilian experience be attributed.

TWO BOARDS BETTER THAN ONE?

WE stated last week that the Ministry of National Service is now concerned in the discharge of men from the army, but that a cumbrous dual system is at present maintained. The procedure now in force appears to be that laid down in a recent circular letter issued by the War Office to general officers commanding at home. All soldiers sent to a discharge centre, whether for discharge or transfer to the Reserve, are in the first instance to be brought before a civilian medical board attached to the centre. Detailed instructions are given to the officer commanding the discharge centre, who in every case is the approving authority for discharge or transfer to the Reserve, and is responsible for producing to the board all the documents properly completed for each case. "The object of bringing the soldier before the civilian medical board is to ascertain whether he has been impaired or not in health since his entry into the service." The civilian board is accordingly instructed to answer this question, and also to recategorize the soldier. The procedure thereafter varies according to the finding of the civilian medical board. Special instructions are given for the disposal of a soldier the board is not able to recategorize. In this event the man and his documents are to be brought before a military board at the discharge centre, which will either recommend the soldier's discharge or, if it considers him unfit for any medical category required in the army, will recategorize him—which may be easier than it sounds. The documents then come again before the officer commanding the discharge centre, who will approve the soldier's discharge in accordance with the King's Regulations. Where a soldier has been sent to the centre not with a view to discharge from the army, but for the purpose of transfer to the Reserve, the procedure varies slightly in detail. Pending the issue of a new Army Council Instruction, all discharges from discharge centres and transfers to the Reserve are to be effected under the provisions of this War Office letter. A sidelight on the amount of clerical work thrown upon all concerned appears to be given by the statement that in the event of one civilian board being insufficient to give effect to the instructions contained in this letter, a wire is to be sent to the War Office stating how many more boards are needed.

INTERALLIED SCIENTIFIC FOOD COMMITTEE.

THE second meeting of the Interallied Scientific Food Committee was opened in Rome on April 30th by Signor Crespi, Italian Commissary-General of Food Supply. A Reuter's telegram states that, after welcoming the delegates, Signor Crespi explained Italy's requirements during and after the war, and described the legislation recently adopted there to restrict supply and consumption. Signor Crespi's welcome was acknowledged by Professor E. Gley (France), Professor R. H. Chittenden (U.S.A.), and Professor E. H. Starling (Great Britain). The first meeting of the committee, it may be remembered, was held in Paris from March 25th to March 29th. Many important questions relating to the minimum food requirements of man and to the production and distribution of food supplies were then discussed. It is hoped that the labours of the conference now sitting in Rome may result in early action. Italy is following the example of France in instituting meatless days. In France the new order, which comes into force on May 15th, forbids the sale of meat on three days a week—Wednesday, Thursday, and Friday—or the supply of meat dishes in any public place, whether hotel, restaurant, dining car, or club, on those days. The only exception is that the sale of horse-flesh is permitted, but only in shops exclusively devoted to it. The abattoirs will be closed from Monday evening till Friday morning. The number of animals that may be killed is restricted to two-thirds of the average number in the weeks of March, 1918. In Italy the same days are selected to be meatless, but there

mutton, lamb, and goat's flesh may be sold on Wednesdays, and bacon and salt pork and offal of all kinds, but not sausages or trotters, on any day. The sale of fowls is limited to three days a week, and in hotels and restaurants no meat of any sort may be served on the three meatless days with the exception of offal and rabbit. In Rome the proportion of maize and rice in bread is to be increased during the next fortnight at least. The price of meat in Italy, as also of ham and bacou, is very high.

THE Allied Conference on the after-care of disabled sailors and soldiers will meet again in London at the end of this month. In connexion with it an exhibition will be arranged of appliances in use in the British and allied nations for the benefit of the maimed and disabled; it will include a considerable collection of such appliances used in military orthopaedic hospitals in this country.

SEVERAL cases of the disease presenting cerebral symptoms, generally believed to be botulism, are now under treatment in Guy's Hospital. Two of the physicians to the hospital will be pleased to demonstrate them to any medical practitioners who may care to visit the wards at 3.30 and 4 p.m. on Monday next, May 6th.

Medical Notes in Parliament.

The Budget.

THE salient features of the Budget were summarized in our last issue; it may be convenient to record here a few notes of the subsequent debate. As the Chancellor remarked towards the end of the discussion, the Budget was well received on the whole, though every increase in taxation was criticized with some force by one member or another. On many points opinions were almost, if not quite, unanimous, as, for example, that Mr. Bonar Law deserved hearty thanks for his clear statement and a personal tribute to his tenacious memory for facts and figures, that his proposals were on the whole reasonable enough, that the luxury tax was a difficult but desirable departure, that the country was anxious that Treasury activity should be concerned not only with raising money but also with discouraging avoidable extravagance, that there were difficult times ahead needing much financial acumen on the part of the Government and severe sacrifice on the part of all, and last—and perhaps not least—that the Chancellor would find his smaller taxes—the additional penny per cheque and the increased postal rates—the most difficult to get through.

One or two members—including Mr. McKenna, the ex-Chancellor—would have been willing to see the income tax still further increased to 6s. 8d., or even 7s. 6d.—at any rate, during the continuance of the war; and from the Labour benches came a plea for the increase of the rate of excess profits duty from 80 per cent. to 90 per cent. or 100 per cent.; the force of this plea was weakened, if not destroyed, by the arguments brought forward by Mr. Baldwin, Joint Secretary to the Treasury. The suggestion made in some quarters—as was the case last year—that this duty should be extended to professional as well as business incomes, is dealt with in a leading article this week. The addition to the income tax to be paid by farmers met with ungrudging support from some and opposition from others. Mr. Wiles made a legitimate debating point by quoting cases in which farmers had alleged large pre-war profits when claiming compensation from the Losses Commission—for example, on being displaced when an aerodrome was established. He suggested that although when it was a question of taxing profits a farmer kept no accounts, figures were usually available for compensation purposes. Generally the feeling was that farmers had no reason to complain, as in any case they could claim to pay on their profits instead of on the artificial basis of twice the amount of their rent if they felt aggrieved.

The raising of the income limit for relief in respect of children from £700 to £800 was appreciated, though that

change has apparently been due rather to the exaggerated effect of the £700 limit last year, which barred both the £70 abatement as well as the £25 per child, than to any deliberate intention to extend the latter allowance. Mr. H. Samuel suggested, and the Government spokesman (Mr. Baldwin) accepted the suggestion, that there was a continuing tendency to put the income tax more upon a family than upon an individual basis, and that that principle will have to be taken into consideration by the Income Tax Committee to be set up at the conclusion of the war.

The Budget for 1918 does not affect medical men as such, though they come within the class of income-tax payers which is substantially affected by the new rates in force for incomes over £500 per annum. Those who are drawing pay as officers in the army or navy will join those members who expressed their pleasure that the Chancellor had left last year's special "service" rates of income tax to hold good for 1918.

Promotion in Royal Army Medical Corps.—Mr. Macpherson stated in answer to Sir William Collins, on April 29th, that seventeen officers in the Army Medical Service had been promoted to the rank of major-general during the last five months. Of these five were men who held world-wide reputations for scientific and professional work, and twelve were promoted for both professional and administrative work.

Medical Examinations for the Army.—Replying, on April 25th, to a question by Mr. Jowett as to the arrangement for newly enlisted men and volunteers at military depôts, Mr. Macpherson said that the recruit was medically examined and graded before being handed over to the army by the Ministry of National Service. The subsequent examination at the reception depôt (prior to posting) was merely for the purpose of detecting whether a man was suffering from an infectious disease.

Mesopotamia Campaign: Surgeon-General MacNeece exonerated.—Mr. Macpherson, in a written answer to a question by Sir Watson Cheyne on May 1st, said that the Army Council had received and considered a statement by Surgeon-General MacNeece on the findings of the Mesopotamia Commission in his case, and they had formed the opinion that no blame could be attached to him in regard to the manner in which he carried out his duties in connexion with the medical services during the campaign.

Temporary Medical Officers in France.—Mr. Watt asked, on May 1st, whether a memorandum had recently been sent to temporary medical officers in France, when yearly contracts were about to expire, stating that they would be required to renew their agreements unless their release were asked for by some public body, or by a medical practitioner, requiring their services at home. Mr. Macpherson replied that he was not aware of any memorandum of the nature suggested. A letter from the Ministry of National Service had been sent to all such officers requesting them to continue their services in the R.A.M.C. on the expiration of their contracts. The letter also stated that the privilege which had hitherto been accorded, that such officers might put before the Central Professional Committees any difficulties which individuals might have in continuing their services, would not be affected.

British Prisoners of War in Turkey.—Mr. Fitzalan Hope, on April 29th, said that the first thousand British invalided prisoners to be repatriated from Turkey will be chosen by the Turkish authorities without the formality of official medical inspection in order to save time. The further selection would be made by medical commissions composed of two Turkish doctors and one British prisoner doctor. The standard of disability for repatriation from Turkey under the agreement was the same as that in force with Germany for the purpose of transfer from that country for internment in Switzerland. The Netherlands Minister (Constantinople) had been requested to carry out the provisions of the Berne agreement as to the inspection of internment camps by his representatives.

MR. FORSTER has stated that the reduction made some time ago in the rations of sedentary troops had not been found successful and the subject was being further considered.

IN the new case installed in the Central Hall of the Natural History Museum, Cromwell Road, London, the subject of plant foods is dealt with. The several sections of the exhibit comprise cereals, bread, roots, and tubers and other "vegetables," nuts, the pulses, fresh fruits, beverages, and sugar and its substitutes. The plants most generally used in the United Kingdom for foodstuffs are shown by specimens, models, drawings, and diagrams. The values of some typical foods in energy and in building power are shown in a series of coloured diagrams, and comparison is easy, as all the diagrams are on the same scale and each colour has the same significance throughout.

THE WAR.

TREATMENT OF WOUNDS IN WAR.

(Continued from p. 490.)

The following are further sections of the conclusions of the Inter-Allied Surgical Conference at Val-de-Grâce from March 11th to 16th.

II. TRENCH FOOT.

1. Trench foot is a pathological condition provoked by moist cold and complicated as a rule by secondary infection.

2. The disorder presents four stages, as follows: (1) Painful anaesthesia; (2) oedema; (3) phlyctenules; (4) sloughing. Three clinical forms may be described—(a) slight (85 to 90 per cent. of the cases), characterized by painful anaesthesia, oedema, and redness; (b) moderate (13 to 14 per cent.), characterized by phlyctenules and limited sloughs; (c) severe (1 per cent. on an average), characterized by extension of sloughing and the appearance of septicaemic complication. This form may produce serious mutilation or death.

3. Trench foot, especially the more serious forms, is not infrequently complicated by tetanus or gas gangrene, and relapses and recurrences may take place. Trench foot occurs almost exclusively in soldiers who live in the trenches, more particularly in certain trenches. Soldiers coming from hot countries, dark-skinned races particularly, are more frequently attacked than Europeans. (In Italy soldiers from the south have suffered more often than soldiers from the north.) Youth, hyperidrosis, and a previous attack are predisposing causes.

4. Blood stasis due to prolonged standing, to long immobility, and to a bad attitude (stooping), compression of the leg and interference with the venous circulation, particularly by puttees, and more especially remaining long in cold and damp (muddy and flooded ditches and shell holes), are the principal causes of trench foot.

5. Trench foot may be confused with true frost-bite and with chilblains. True frost-bite is characterized by sudden massive mortification of a part of a limb (the front of the foot, the whole foot, etc.); trench foot, on the contrary, is characterized by limited destruction (gangrenous patches on the dorsum of the foot, the sole, or the toes) and by progressive invasion of the tissues of the foot. Frost-bite is met with in severe dry cold, especially in mountainous regions. Trench foot occurs only in damp weather and at low altitudes (valleys, plains); it disappears in frost. Chilblains are characterized—at any rate, in their early stages—by very severe itching, whereas those forms of trench foot—that is to say, the slight forms—which are liable to be confused with chilblains produce painful anaesthesia without any itching. It has to be admitted, however, that sometimes the diagnosis between ulcerated chilblains and the ulcerated phlyctenules of trench foot may be doubtful.

6. The treatment of trench foot is preventive and curative. Preventive treatment energetically applied and supervised may be followed by the disappearance of cases of trench foot, or may at least render them very rare. The treatment includes (a) collective measures—hygiene and draining of the trenches, gratings, trench boots, dry warmed shelters, with, if necessary, frequent reliefs; and (b) individual preventive precautions taken daily (drying, cleansing and massage of the feet, change of socks in the shelters, supervision of puttees and of everything which can cause compression of the lower limbs). Belgian medical officers attribute the extreme rarity of cases of trench foot in their army to the disuse of puttees. The curative treatment of trench foot includes the following measures: (a) Slight cases; a warm foot bath should be taken every two or three days and the feet washed with borie camphor soap. A large moist borie camphor dressing should be applied to the foot every day. (b) Severe cases; when phlyctenules only are present they should be opened and touched with camphorated ether, and a moist borie camphor dressing applied. If there are sloughs the same treatment should be persistently applied. Sloughs should not be removed with the knife; they should only be scarified, without causing bleeding, so that the drugs used may act on the subjacent tissues. Spontaneous separation must be awaited, and complications carefully

watched and thoroughly treated surgically and fully at their onset. The principle by which operation ought to be guided is that it should be late and confined to the rectification of stumps which are defective from a functional point of view. Amputation should be performed only in cases in which the surgeon's hand is forced by serious general complications. In every case preventive antitetanic treatment should be used (injection of antitetanic serum repeated every week until the wound is cicatrized).

III. THE TREATMENT OF WOUNDS OF THE PELVIS, AND OF THE BLADDER AND RECTUM IN PARTICULAR.

Of the Pelvis Alone.—The general principles are the same as for war wounds of soft and bony parts. Comminuted fractures of the ilium call in particular for large trephining. The removal of projectiles or bony fragments which are often driven into the psoas and iliacus muscles is particularly difficult, and must be carried out systematically.

Of the Bladder.—(a) Intraperitoneal wounds are amenable to laparotomy and suture; (b) extraperitoneal wounds, if suprapubic, should be treated by primary suture of the bladder. Wounds of the walls or base of the bladder inaccessible to operation do not entail immediate cystotomy as a matter of routine. Surgical treatment of the wound of entry and of its track will assure sufficient drainage. Later on tying in of a sound will favour the closing of the urinary fistula. Primary cystotomy should be reserved for wounds of the bladder with retention or progressive perivesical infiltration. Serious haematuria or the presence of a foreign body in the bladder justify early cystotomy. Secondary infection of the bladder calls for cystotomy with drainage.

Of the Rectum.—(a) Intraperitoneal wounds, like all other wounds of the intestine, are amenable to laparotomy with suture; (b) the majority of cases of extraperitoneal wounds should be treated by the laying open of the traumatic centre, followed by plugging of the rectal wound. An indispensable adjuvant to this treatment is to keep the bowels constipated. In rupture with extensive detachment the method of choice is free opening up, with, if necessary, posterior rectotomy. Primary colostomy is only exceptionally required.

Combined Wounds of Bladder and Rectum.—The greater number of cases will recover under surgical treatment of the extravascular tract of the projectile. Colostomy should be reserved for cases in which the communications between the bladder and rectum are very extensive. Primary cystotomy is often useless; the tying in of a sound, ventral decubitus, and micturition in the genu-pectoral position favour spontaneous closure of the vesico-rectal fistula.

(To be continued.)

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Missing.

Surgeon H. C. Broadhurst, R.N.

Surgeon W. A. McKerrow, R.N.

ARMY.

Killed in Action.

MAJOR J. S. WALLACE, M.C., R.A.M.C. (T.F.).

Major Joseph Stephen Wallace, whose death in action was recorded in our issue of April 20th, held a commission in the Territorial Force, and not a temporary commission as stated. He was gazetted to the 2/2nd Welsh Field Ambulance on December 25th, 1915, and received his captaincy on July 25th, 1916. He joined the 2/3rd London Field Ambulance on August 9th, 1916. His commanding officer writes that Major Wallace was an exceptionally brilliant bearer officer, always ready for any work, and absolutely regardless of himself. He was awarded the M.C. on July 26th, 1917, for brilliant services during the battle of Arras, and a bar to the M.C. on January 8th, 1918, for exceptional work during the battle of Cambrai. He was held in the highest esteem by every member of the mess, and his stretcher-bearers worshipped him. He met his death while gallantly going to try and find another officer who was reported missing.

CAPTAIN B. S. BROWNE, M.C., R.A.M.C.

Captain Bernard Score Browne, M.C., R.A.M.C., was killed in action on April 15th. He was the son of Colonel A. Walker Browne of Londonderry, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1908. He then went out to China, where he served as a medical missionary of the C.M.S., and also as surgeon to the Chinese Customs Service at Ningpo, and received the Chinese Order of the Dragon. He took a temporary commission as lieutenant in the R.A.M.C. on April 2nd, 1915, and was promoted to captain after a year's service. He got the Military Cross on November 4th, 1915.

Wounded.

Lieut.-Colonel A. C. Rankin, Canadian A.M.C.
Major W. T. Brown, M.C., R.A.M.C. (temporary).
Major T. W. Clarke, M.C., R.A.M.C. (S.R.).
Major C. B. Davies, M.C., R.A.M.C. (temporary).
Major W. S. Garnett, Australian A.M.C.
Captain M. Avent, R.A.M.C. (S.R.).
Captain T. Bennett, R.A.M.C. (temporary).
Captain A. G. Cook, R.A.M.C. (temporary).
Captain R. Donald, R.A.M.C. (temporary).
Captain F. G. Foster, R.A.M.C. (S.R.).
Captain F. P. Freeman, M.C., R.A.M.C. (S.R.).
Captain M. R. Graham, Canadian A.M.C.
Captain C. H. Harbinson, R.A.M.C. (temporary).
Captain S. P. Hodgkinson, R.A.M.C. (temporary).
Captain D. L. Kennedy, Canadian A.M.C.
Captain G. D. Latimer, R.A.M.C. (temporary).
Captain T. McEwen, M.C., R.A.M.C. (S.R.).
Captain H. G. Oliver, R.A.M.C. (temporary).
Captain A. R. Oram, R.A.M.C. (temporary).
Captain R. H. C. Pryn, R.A.M.C. (temporary).
Captain I. A. N. Scott, R.A.M.C. (temporary).
Captain J. Smith, R.A.M.C. (temporary).
Captain G. Steel, R.A.M.C. (temporary).
Captain R. I. Sullivan, M.C., R.A.M.C. (S.R.).
Captain W. A. Troup, M.C., R.A.M.C. (temporary).
Captain F. W. White, R.A.M.C. (temporary).
Captain G. Wilson, Canadian A.M.C.

Missing.

Captain W. J. Isbister, M.C., R.A.M.C. (temporary).
Captain G. L. Jones, R.A.M.C. (S.R.).
Captain L. C. Maclean, D.S.O., R.A.M.C. (temporary).
Captain F. P. Smith, R.A.M.C. (temporary).
Lieutenant J. F. Hornsey, R.A.M.C. (temporary).
Lieutenant E. S. Phillips, R.A.M.C. (temporary).

Formerly reported Missing, now not Missing.

Captain E. J. Storer, R.A.M.C. (temporary).

Prisoners of War.

Captain A. G. Bisset, M.C., R.A.M.C. (temporary).
Captain P. B. Corbett, R.A.M.C. (S.R.).
Captain D. R. E. Roberts, R.A.M.C. (temporary).
Captain H. A. Sandiford, R.A.M.C. (T.F.).
Captain W. Warburton, R.A.M.C. (temporary).
Lieutenant O. Le F. Milburn, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Awdry, W. W., Lieutenant Wiltshire Regiment, eldest son of Dr. W. R. Awdry of Berkeley, Gloucestershire, died of wounds on April 14th, aged 22. He was educated at Sherborne, entered Sandhurst in 1915, got his commission in 1916, went to France soon after, was wounded at Thiepval, and returned to the front only fourteen days before his death.

Chamberlain, Arthur Beaumont Goddard Twyford, Lieutenant Royal Navy, only son of Dr. E. Twyford Chamberlain of Billingham, killed April 23rd, aged 28. He had seniority as lieutenant from June 26th, 1911.

Hamilton, Ronald Eric, Second Lieutenant Devonshire Regiment, younger son of Dr. E. A. Hamilton of Manea, Cambridgeshire, reported wounded and missing, now presumed killed, April 23rd, 1917, aged 20.

Kent, Percival Naylor, Lieutenant-Colonel Dragoon Guards, son of the late Dr. J. G. Kent of Kingston, died of appendicitis in a base hospital abroad, April 18th. He was born in 1870, got his first commission in 1894, and retired as captain in 1912, when he joined the reserve of officers. He became major in the Notts Yeomanry, Sherwood Rangers, on May 13th, 1914, and was promoted to lieutenant-colonel in 1917.

Lawson, James Burnett, Lieutenant (Cameronians) Scottish Rifles, youngest son of Dr. J. B. Lawson of Rothesay, killed in action March 27th, aged 21. He had completed his first year as a medical student and passed his first professional examination at Glasgow University. He was a member of the University O.T.C., and obtained his commission in August, 1915. He took

part in the battles of the Somme in 1916, and was promoted lieutenant in October, 1916. He was acting captain at the Ypres battle on July 31st, 1917. He was expected to return to resume studies on April 24th.

Loudon, James Brugh, Lieutenant Scottish Rifles (Cameronians), son of Surgeon-Major Livingstone Loudon, killed April 15th, aged 21. His commission was dated March 17th, 1915.

Maclean, Harold Daniel, Royal Field Artillery, younger son of Dr. Maclean of Stonehouse, Lanark, killed April 12th, aged 20.

Murray, George Anthony, M.C., Captain Royal Field Artillery, son of Lieut.-Colonel C. F. K. Murray, M.D., President of the Medical Council of South Africa, and grandson of Sir John Molteno, died of wounds on April 5th, aged 24. He was educated at Bedales and at Trinity College, Cambridge, where he graduated B.A. in June, 1915. He received his commission on July 8th, 1915, went to France on September 18th, 1915, and had been at the front ever since, taking part in the battles of Ypres, the Somme, Arras, and Passchendaele. He received the M.C. on September 15th, 1916, was promoted to lieutenant early in 1917, and to acting captain in November, 1917.

Nolan, M. K., Second Lieutenant Australian Infantry, killed in the heavy fighting on the Somme at the end of March, was the elder son of the late Dr. H. Russell Nolan, formerly anral surgeon to the Royal Prince Alfred Hospital and lecturer on diseases of the nose and throat in the University of Sydney. Lieutenant Nolan was educated at Newington College, Sydney, and at the time of enlistment was studying law at the Sydney University.

Parkinson, George Robert, Flight Lieutenant Royal Navy, only son of the late Dr. Parkinson of Henley-on-Thames, killed flying on patrol, April 13th, aged 19.

Reid, Erio Archdall, Second Lieutenant Hampshire Regiment, only son of Dr. Archdall Reid of Southsea, killed March 28th, aged 19.

MEDICAL STUDENT.

Grant, Thomas F., Second Lieutenant Seaforth Highlanders only son of the late Thomas Grant of Banahrew, killed recently before the war he was a medical student at Edinburgh University. He gained the Military Cross in 1917.

Dr. H. Edmondson (Burnley) informs us that the injury through a shell explosion received by his son, Second Lieutenant I. E. Edmondson, A.S.C., reported killed in our last issue, did not prove fatal, and that he is now making satisfactory progress towards recovery.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

THE following is a continuation from p. 492 of our last issue of the particulars of acts of conspicuous gallantry and devotion to duty for which the decorations announced in the BRITISH MEDICAL JOURNAL, December 22nd, 1917, p. 839, were conferred:

Military Cross.

Temporary Captain Everard Cecil Abraham, R.A.M.C.

When in charge of a bearer division during seven days' operations the rapid and efficient clearing of wounded from the field was largely due to his efforts. During a heavy gas shell bombardment he led his bearers through the barrage to rescue men affected by the gas.

Temporary Captain William Robert Addis, R.A.M.C.

He superintended the clearing of wounded from regimental aid posts while the whole area was being heavily shelled, and during the latter part of the period he was gassed, but remained at work until the relief was finished.

Captain Matthew Thomas Ascongh, R.A.M.C.

He dressed wounded in the open for forty-eight hours, without sleep or rest, under heavy shell fire, after his shelter had been rendered untenable by four direct hits.

Lieutenant Robert Hector Baxter, N.Z.M.C.

He worked for three days at his regimental aid posts under continual exposure to shell and machine-gun fire.

Temporary Captain Arthur Cecil Barker Biggs, R.A.M.C.

He supervised the removal of the wounded under very heavy fire during two days' operations. It was due to his extraordinary energy that the battlefield was always kept clear of the wounded, in spite of very adverse conditions.

Temporary Captain George Alexander Birnie, R.A.M.C.

In going forward with two stretcher-bearers to form an advanced aid post he was wounded in the shoulder by a piece of shell, one of the stretcher-bearers being killed at the same time. He continued dressing the wounded in our most advanced line, and even penetrated the enemy line of posts in search of casualties, keeping at his work until relieved some eight hours later.

Temporary Lieutenant Charles Herbert Booth, R.A.M.C.

He tended the wounded in the open under continuous heavy shell fire. His skilful organizing of stretcher-bearers was undoubtedly the means of saving many lives.

Temporary Captain Robert Briffault, R.A.M.C.

He organized an aid post through which all casualties of the brigade and those of many other units of the division passed. He personally went up to the post and attended to men lying out in shell holes under very heavy fire. Although relieved, he actually went up beyond our forward posts to search for a wounded officer. Throughout the whole action he showed the utmost disregard for his personal safety.

Temporary Captain George Edwin Chissell, R.A.M.C.

He tended the wounded both of his own battalion and others and organized their evacuation. He worked continuously in the open for twenty-four hours under heavy shell and machine-gun fire. When the battalion was relieved he remained until the last man of his brigade had been taken away.

Temporary Captain Edward James Clark, R.A.M.C.

As medical officer to a battalion, though continuously under heavy shell fire, he moved about in the open attending to the wounded, and undoubtedly saved many lives.

Temporary Lieutenant Arthur Philip Draper, R.A.M.C.

He set a splendid example of courage and self-sacrifice in attending to the wounded during an action. He went forward and attended to the wounded in the open when heavy casualties had been caused among the stretcher-bearers, and by his gallant conduct undoubtedly saved several lives.

Temporary Captain Frederick Pearson Fisher, R.A.M.C.

On learning that the enemy had projected gas into one of our deep mine galleries, he descended to the bottom of the main shaft and established an aid post there. He then advanced with his party into the gassed area and rescued several miners. He remained at his post without relief for fourteen hours and saved many lives.

Temporary Captain Alistair Gordon Forbes, S.A.M.C.

After continuous dressing of thirty wounded he personally took a place in one of the squads of bearers under heavy fire of gas and other shells, and so stimulated his exhausted bearers to special efforts. Though suffering from mustard-gas poisoning, he remained at work until ordered back as a casualty two days later.

Captain Hartas Foxton, R.A.M.C.

When in charge of the collection of wounded he personally directed and visited all the regimental posts many times a day, often under heavy fire. By his energy he kept his bearers working, though exhausted, until the completion of the evacuation.

Captain Reginald Douglas Gawn, R.A.M.C.

He worked untiringly, attending to the wounded under heavy fire during an attack. He made several journeys over most difficult ground to reach wounded men who were lying out in the open, and showed splendid courage and gallantry throughout.

Captain Norman Bell Graham, R.A.M.C.(S.R.).

He worked unceasingly under very heavy shell fire, attending to the wounded of several units. He organized stretcher parties, and also went out himself to attend to the wounded. He set a splendid example of contempt of danger, and undoubtedly saved many lives.

Lieutenant Arthur Robert Hill, R.A.M.C.(S.R.).

He attended to the wounded during an attack in a very exposed position under heavy shell fire. He often moved about over the open, searching for the wounded and assisting to remove them. He showed great coolness and resource under the most difficult and dangerous conditions.

Captain William Baly Jepson, R.A.M.C.(S.R.).

When a shell had smashed in battalion head quarters, although severely shaken himself, he dug out his commanding officer and the adjutant, and attended to them. He continuously took stretcher-bearers to the front line in daylight through intense shell fire. He established a new forward dressing-station after the battalion had been relieved, and did not return till he had searched the whole front for wounded.

Captain Frederick William Lumsden, N.Z.M.C.

He dressed wounded in the open when the regimental aid post which was within 700 yards of the enemy "pill-boxes" and in full view of them, was still full of wounded left by the previous battalion. Casualties were inflicted even on the stretcher cases. Though exposed to this fire, he worked unrelentingly for three days, with practically no sleep and very little food, until quite exhausted.

Captain Duncan Macfadyen, R.A.M.C.(S.R.).

He repeatedly went out to shell holes under heavy fire to dress the wounded and help bring them in. He attended to the wounded of another battalion in addition to those of his own. He showed splendid courage and self-sacrifice.

Captain John McGhie, N.Z.M.C.

When in charge of bearers time after time he took stretcher parties forward through heavy mud and enemy barages to the regimental aid post, and did not stop till he was certain that all men lying out had been collected.

Captain James McKay, M.B., R.A.M.C.(S.R.).

He arranged the evacuation of stretcher cases from the front line, and continually dressed wounded, regardless of heavy shelling, in the open, owing to limited accommodation.

Captain Hugh Agnew Macmillan, R.A.M.C.

He passed some 600 cases through his regimental aid post, though it was heavily bombarded. His staff being much depleted, he had to treat the majority of cases himself.

Temporary Surgeon Richard Glyn Morgan, R.N.

When wounded he carried on his duties under very heavy shell and rifle fire. Even when wounded a second time he worked with the stretcher-bearers in the open for thirty-six hours, until all the ground had been cleared of wounded. It was largely owing to his wonderful example and great exertions that the ground was cleared so quickly.

Captain John Pinder, R.A.M.C.

He attended to wounded under continuous shell fire. During two days and nights he worked in a shell hole and sent back a large number of wounded men who would otherwise have died from exposure. He also went forward several times to the front line to attend to wounded men.

Temporary Captain Charles Leslie Grove Powell, R.A.M.C.

He carried on his work in the open under fire, though his advanced aid post was a special target for the enemy's artillery. He also visited the front line when it was being heavily shelled to attend to cases that could not be moved.

Lieutenant (temporary Captain) William Leonard Eliot Reynolds, R.A.M.C.

He worked continuously for twenty-four hours amongst the wounded. In addition to his work at the regimental aid post he

went to the front line frequently, by day and night attending the wounded under heavy fire.

Captain Sydney Devenish Rhind, N.Z.M.C.

For three days and nights at his regimental aid post he repeatedly attended to men outside under heavy fire. He also organized parties of stretcher-bearers for their removal.

Captain William Jack Scade, R.A.M.C.

When there was a large number of wounded in the aid post and no stretcher-bearers were available, he went back a distance of over a mile through a very heavy barrage, brought back stretcher-bearers and removed all the wounded. On the following day he went up to the front line under snipers' fire and brought back several wounded men. His courage and initiative were the means of saving many lives.

Captain Samuel Llewellyn Serpell, N.Z.M.C.

He attended to the wounded at the regimental aid post under heavy fire. Although twice wounded, he went on with his work until ordered to hospital by his commanding officer.

Captain Charles Nixon Smith, R.A.M.C.

When in charge of the collection of casualties from the whole of the divisional front during active operations he worked unceasingly for seven days without adequate sleep or food, and it was largely owing to his personal influence that the exhausted bearers were able and anxious to remain at work for so long a time.

Captain Walter Leonard Smith, A.A.M.C.

While in charge of stretcher-bearers and posts he did magnificent work in attending to the wounded and organizing their removal, and by his fearlessness and determination set a splendid example to his stretcher-bearers.

Temporary Captain William Steadman, R.A.M.C.

He superintended the loading of wounded men on to the tramway, and assisted the stretcher-bearers, under heavy fire. He also repeatedly went in search of wounded, and was the means of bringing a large number to safety. Later, though gassed, he continued at duty.

Temporary Captain Frederick Naylor Stewart, R.A.M.C.

He attended to the wounded during an action with utter disregard of danger, working in the open most of the day under persistent shell fire. He was untiring in his efforts on behalf of the wounded, and showed splendid courage and determination.

Temporary Lieutenant (temporary Captain) Robert Ievers Sullivan, R.A.M.C.

He attended the wounded under heavy fire. He organized the stretcher-bearers, and for thirty-six hours searched in front of our outposts for wounded men, thereby saving many lives.

Temporary Captain Norman Charles Talbot, R.A.M.C.

On hearing that the batteries of the brigade were being heavily shelled he dashed forward and dressed and collected over twenty wounded men.

Captain Robert Fowler Walker, R.A.M.C.(S.R.).

He tended the wounded in the open after the aid post had become a target for the enemy's howitzers. He was severely wounded, but would not allow the bearers to remove him until he had given instructions to his N.C.O. and made all possible arrangements for the care and comfort of the wounded.

Temporary Captain Henry Currie Watson, R.A.M.C.

He worked continuously for three days at an advanced dressing station which was being constantly shelled. Although gassed he persisted in remaining at duty.

Temporary Lieutenant Robert Everard Whitting, R.A.M.C.

He attended to the wounded during an engagement continuously for forty hours, working most of the time in the open under heavy shell fire. His courage and devotion to duty undoubtedly saved a very large number of lives.

Temporary Captain Frederick Edward Saxby Willis, R.A.M.C.

He attended the wounded of his own and other units in advance of our front line and in forward positions which were fully exposed under heavy fire. It was largely due to his careful training and skilful arrangements that his bearers evacuated such a large proportion of the wounded of three units from the front area during the two days.

The honour of C.I.E. has been conferred upon Major (Brevet Lieut.-Colonel) Cecil M. Goodbody, D.S.O., I.M.S., Major (temporary Lieut.-Colonel) James G. Swan, I.M.S., and Major William D. H. Stevenson, I.M.S., in recognition of meritorious services in Mesopotamia under the command of the late Lieut.-General Sir Stanley Maude.

NOTES.**SHELL SPLINTERS IN THE AXILLARY ARTERY.**

PATEL, who in civil life is surgeon to the hospitals of Lyons, has recorded in *Paris médical* a case in which a fragment of shell was removed from the interior of the axillary artery. The man was struck on the right side of the thorax, a little below the nipple, and the projectile lodged in the corresponding axilla. There was slight tingling in the right arm; the right hand was weaker than the left and the pulse was smaller. An incision as for ligature of the axillary artery was made, the median nerve exposed and held back; the fragment of shell was not found in the periarterial cellular tissue but appeared to be embedded in the arterial wall. On cutting directly on to the foreign body it was found to be lying within the lumen of the vessel. It was removed. There was some haemorrhage and the artery was sutured with five stitches. Healing took place by first intention and the pulse became normal. Patel thinks the foreign body lodged first in the outer coat of the artery and was

gradually pushed into the interior by the force of the pulse beat or by pressure against the outer wall of the axilla. The process was made easy by the fact that there was a miniature aneurysm in course of development at the point of penetration and the vessel was thus weakened.

VENEREAL DISEASES IN THE FRENCH ARMY.

The problem of prostitution in armies has always been a difficultly, and has been dealt with in different ways by commanding officers. The Duke of Alva had the female camp followers in the Netherlands regularly organized. The higher grade for the officers rode on horseback in fashionable attire, while the common women for the rank and file went on foot. On the other hand, Strozzi cast 800 prostitutes into a river at one fell swoop. In a Huguenot army in the sixteenth century soldiers were compelled to marry the women. In other campaigns soldiers and prostitutes were impartially flogged, pilloried, and put in the stocks. Women were made to "run the gauntlet" between two files of men who beat them as they passed, but none of these measures was of any use. In the eighteenth century Voltaire, in *L'Homme aux quarante écus*, attributed the dissemination of syphilis among the civil population to the troops, and suggested the institution of an international crusade for the suppression of the scourge. In a volume on the sexual pathology of the soldier which has lately appeared, Dr. Fiaux estimates that late in the eighteenth century two out of every three men in the French army were syphilitic. During the French Revolution three admissions to a hospital were considered to make a man "unworthy to serve his country." The necessity of prompt cure was recognized, and barracks and camps were flooded with so-called "specialists," who vaunted their nostrums. One Boyveau-La-Hauteur had a specific which he called "206." In Berlin, when under French rule, and in Paris at the same time, an attempt was made to regulate prostitution, and any breach of the ordinances was severely punished. In 1814 it was shown that in houses under police supervision only one woman in seven was infected, whereas among clandestine prostitutes the rate was one in four. The close of the Napoleonic wars brought some change, but the percentage of infection remained very high. In the middle of the nineteenth century the average incidence was 10 per cent., but in some places it was much higher. After the Franco-Prussian war the figures were better: in 1889 the ratio of infections fell to about 5 per cent., and in 1895 to 3.75. Syphilis showed the largest reduction; in 1911 the ratio was below 2.5 per cent. Gonorrhoea was reduced by one-half between 1880 and 1911. Before the war the troops were professional soldiers, while to day there is a citizen army which sooner or later must be disbanded; it is feared in France that, unless drastic precautions are taken, the disease will be widely disseminated among the population.

Scotland.

THE CHAIR OF MATERIA MEDICA, EDINBURGH.

SIR THOMAS R. FRASER, who succeeded Sir Robert Christison as professor of materia medica in the University of Edinburgh in 1877, has tendered his resignation, to take effect at the end of the present financial year. He has been professor of clinical medicine also since 1878. Sir Thomas Fraser is physician to the King in Scotland. He graduated M.D. Edin. in 1862, and was President of the Royal College of Physicians of Edinburgh in 1900-1902.

OVERCROWDED MEDICAL CLASSES.

At a meeting of the Glasgow University Court a letter was read from Professor Noel Paton, stating that an abnormal increase in the number of students was causing great pressure on the accommodation and teaching staff of the physiological department. The class had been conducted in three sections, and the strain upon the staff was very severe. He suggested that junior students should be excluded from the class in histology, but the question of providing more accommodation and an adequate staff would have to be faced in the near future. Principal Sir Donald MacAlister, who presided, stated that in the botany class there were 337 students, and in the anatomy class 480. It was further stated that the same condition of affairs did not exist in Edinburgh, the increase in Glasgow being much larger. The Principal acknowledged the manifold way in which the reduced staff were working double and treble time. It was agreed to suggest to the senate that the practical course in histology should be suspended during the present summer session.

GEORGE GUTHRIE'S FUND.

A sum in investments amounting to £21,044 has been given by Mrs. Lucy Wortham James, of St. James,

Missouri, U.S.A., to form a "George Guthrie's Fund" in memory of Lieutenant George Watson Guthrie, R.A.M.C., who was killed in action at Beaucourt, France, on November 13th, 1916. The fund has been placed in the hands of trustees, and the income is to be used for educating and training for professional life or business the sons of Scottish officers, warrant officers, non-commissioned officers and men of the British navy and army who have served in the war, and who have either been killed in action, drowned, or died of wounds, accidents, or illness contracted in the course of active service, or who have been so disabled during such service as to be unable to give their sons such a position, education, and training as would otherwise have been possible. The trustees are to hold the fund until twenty-five years from the final cessation of hostilities. It is then to be handed over to the University Court of Edinburgh to found and endow post-graduate fellowships, to be known as "George Guthrie's Fellowships," to encourage research work in the laboratories of the University of Edinburgh in regard to the maintenance of health and the prevention of disease in children, priority being given to preventable conditions such as poliomyelitis or other diseases which may be of immediate importance.

A MINISTRY OF HEALTH.

The Council of the Royal Faculty of Physicians and Surgeons of Glasgow and a special committee of Fellows have recently considered the proposal to institute a Ministry of Health, and their report was submitted to a meeting of the Faculty on April 8th. After discussion, the following resolutions were approved:

1. That a Department of Government should be created to deal exclusively with matters pertaining to the national health.
2. That the administration of existing enactments, in so far as they deal with health, should be transferred to the proposed Department.
3. That this Department should be empowered to initiate any further legislation necessary in order to give full effect to Resolution No. 1.
4. That such Department should be presided over and be represented in Parliament by a Minister of Cabinet rank.
5. That the autonomy of the several parts of the United Kingdom should be conserved by the formation of a Board of Health for each.
6. That such Board should contain *inter alios* persons representative of both the preventive and curative aspects of medicine in all departments, and be competent to advise the Minister as to the adequacy of the public medical, nursing, and hospital services of the country.
7. That the said Board should be aided by an Advisory Committee composed in part of members of the medical profession in groups and numbers to be subsequently considered.

The Faculty unanimously held that in any proposed legislation respecting a Ministry of Health the universities and medical corporations in Scotland should be given ample time to consider such measure before it becomes a statute of the realm.

England and Wales.

INSTITUTIONAL TREATMENT OF DISCHARGED SOLDIERS.

At the meeting of the London Insurance Committee on April 25th it was stated that considerable difficulties were being experienced on account of the competing claims for sanatorium treatment of discharged soldiers and civilian males. The number of discharged soldiers now occupying beds under the Committee's arrangements for the treatment of tuberculosis if 150, and of civilian males 206, and the numbers on the waiting list are respectively 205 and 157. The sum available to the Committee this year for institutional accommodation, including a special grant estimated to amount to £10,000 for the discharged men, is approximately £50,000, which is sufficient to provide an average of 500 beds a week, of which beds 335 are for male patients. If discharged soldiers are consistently to be given preference over civilians (as the Insurance Commissioners have agreed with the Pensions Ministry), and also are to be given treatment for the period regarded as necessary by the Committee's medical adviser, the whole of the available accommodation for males will be occupied

by them, to the exclusion of civilian male patients. The special grant of £10 in respect of each discharged man is the only contribution from outside sources receivable in respect of the treatment afforded to this class, and does not more than pay for five or six weeks' treatment, whereas the average length of stay should be at least twelve weeks. The feeling was expressed that the cost of giving adequate treatment to discharged soldiers should not in the main fall upon funds contributed by or in respect of the civilian male population, to the almost total exclusion of these contributors. A letter was read from the Commissioners stating that the treatment of discharged soldiers must not be excluded from the Committee's scheme; the Committee was responsible for the arrangements in these cases as for other classes of the population who were eligible for benefit, but the Commissioners added that they hoped to be in a position to supplement existing funds by an Exchequer grant. The Committee proposes to send a deputation to the Commissioners in relation to sanatorium benefit arrangements generally.

Correspondence.

UNIVERSITY REPRESENTATION IN PARLIAMENT.

SIR,—In your issue of April 20th Dr. E. Rowland Fothergill takes exception to the formation of a political association in connexion with the combined English universities, though at the same time he somewhat inconsistently suggests that those who think like him should support a candidate who holds views similar to his, forgetting that any association supporting parliamentary candidates is of necessity a political association. His letter is inaccurate in certain particulars, as he must be aware from our reply to a postcard from him some weeks ago. Our committee is not self-constituted, but was elected at a meeting to which were invited all the graduates resident in London whose names and addresses could be found. In addition to those who accepted the invitation, a very much larger number wrote expressing approval of the proposed association.

Dr. Fothergill suggests that we are endeavouring to secure the election of a candidate who holds our views. This, of course, is obvious, and it would also be the purpose of the association which he suggests should be formed. As there are, however, to be two members, and not one, and as these are to be elected under proportional representation, there is no question of our trying to monopolize the representation of the seven universities. He indulges in the gratuitous assumption that our candidate will not be keen on social questions. In this we think he will prove to be wrong, though we would point out to him that many of the so-called "social reforms" merely aggravate the disease which they profess to cure.

In any event, we think it a *sine qua non* that the members who represent the seven universities should be graduates of one or more of them.

While our association has certain definite political objects, it also intends to interest itself in all appropriate educational matters.

Perhaps the best justification for our action lies in the fact that already more than twice as many graduates have expressed approval as there are members of the senates of the seven universities. We mention this because these are presumably the official bodies whom he suggests should wake up. We must protest against the proposal that these official bodies should take any part in the matter, particularly as most of the members thereof will not be electors in the division, being graduates of other universities.—We are, etc.,

W. M. ABBOT ANDERSON,
Chairman.

HERBERT G. WILLIAMS,
Honorary Secretary.

Combined Universities Conservative
and Unionist Association.

130, Ashley Gardens, S.W.1,
April 27th.

THE MILITARY SERVICE ACT, 1918.

SIR,—There is no class in the community who have given their services more freely and ungrudgingly to the nation during these years of stress than the medical pro-

fession. Their reward is to be singled out for compulsory service to an age five years beyond anyone else—an invidious distinction in which Sir Watson Cheyne finds "an honour,"¹ but many of his professional brethren see rather a slight. I have yet to find the medical man here who approves it.

We have heard enough since the war began to convince us that the average general practitioner at home has been working harder than the average man with a commission, either at home or abroad. There are many men from 56 to 65, say, who are still vigorous and active; if the men below this age are largely absorbed into the army, as is suggested by the drift of the Act, these older men will be called upon to bear a very heavy additional strain.

At this stage, surely, the object of the authorities should be to take for the easier work and more regular hours of hospitals, etc., at home and base hospitals abroad, the oldest men fit for them rather than the youngest, and to leave for the severer test of endurance in depleted general practice those who are more active and have a greater reserve of energy.

If the War Office offered commissions for a limited period to those up to 60 or 65, I have no doubt they would have many applications from fit and capable practitioners; and fewer of these older men would break down than under the system which the Act foreshadows.—I am, etc.,

Edinburgh, April 23rd.

R. A. LUNDIE.

P.S.—I am pleased to see a suggestion in the same direction in yesterday's JOURNAL, from an anonymous F.R.C.S.

April 28th.

SIR,—It may be practically futile at this date to say a word more on this question, but it may not, as things have not infrequently been changed or modified during the past three years. I have just learnt that in fixing the age limit the National Service Ministry consulted the English and Welsh war emergency committee, but not the Scottish. Considering the more than generous way in which Scotland has responded to the demands for medical and man service, it surely deserved better treatment than to be ignored. I strongly protest against this action of the National Service Ministry. It would have been wiser to have refrained altogether from fixing an age limit as applied to doctors, for obvious reasons. It has for long been my conviction that the best use has not been, and is not being, made of the medical man service at home and abroad. Great things were hoped for when the Commission appointed to investigate the medical service in France issued its report. Has that report been published?

I believe that a great many more men could be spared for home and foreign service, provided it is gone about in the right way. The only and proper way is by organization.

1. In cities and large towns bureaux should be established, whereby the attendance on the public could be equally distributed among those who are left without doing harm to any one in particular.

2. In one or two men districts the position should be left undisturbed. Substitution would be bad for doctors and public.

3. In populous districts greater use should be made of registered midwives for labour cases, thereby relieving many doctors of the hardship of loss of sleep.

4. Many men over 55 who are retired or semi-retired are perfectly able to undertake part-time service at home, thus relieving younger men for foreign service who at the present time are engaged in clerical work.

5. The public should be educated to expect war-time attendance, not peace attendance.

—I am, etc.,

Edinburgh, April 30th.

MICHAEL DEWAR.

THE EXTRA MILEAGE GRANT.

SIR,—It seems to be little realized that the method of distributing this grant, agreed upon in consultation between the Insurance Commissioners and the Insurance Acts Committee, will result in a very large number of rural practitioners being ruled out of participation in the grant. For instance, in Shropshire, where every practitioner on the panel is a rural practitioner, probably 50 per cent. will receive nothing from the new grant, although every one of the doctors on the panel has incurred increased cost in travelling owing to war conditions. The following case is

¹ BRITISH MEDICAL JOURNAL, April 20th, p. 462.

one I can vouch for: A panel practice of 2,000, 1,200 of whom live more than one mile from a chemist, and up to seven and a half miles from the practitioner, who travels between 9,000 and 10,000 miles a year. This practitioner will not receive anything from the new or extra mileage grant because of the method of distribution which the Insurance Acts Committee agreed to as being equitable. As the mover of the only resolution dealing with this subject at the Conference of Panel Committees, I regret that my remarks were not more fully reported in the account published in the SUPPLEMENT of April 20th.—I am, etc.,

Newport, Salop, April 21st.

THEO. MARTIN CUTHBERT.

Obituary.

J. MICHELL CLARKE, M.D. CANTAB., F.R.C.P. LOND.,

Physician to the Bristol General Hospital and Professor of Medicine in the University.

WE announced last week the death of Dr. J. Michell Clarke of Bristol; he had been ill for some time, and died at Looe, Cornwall, where he had gone for the benefit of his health. He was the son of the late Mr. W. Michell Clarke, surgeon to the Bristol General Hospital, and was 58 years of age. He was educated at Clifton, Caius College, Cambridge, Bristol, and St. Thomas's. He was for a time junior demonstrator of anatomy at Cambridge and afterwards house-physician to St. Thomas's Hospital. He graduated M.B. Camb. in 1885 and M.D. in 1892, became M.R.C.P. in 1887 and Fellow in 1896, and was elected a member of the Council of the College in 1917. His association with the Bristol General Hospital began early, and continued to the time of his death, when he was senior physician. He took a leading part in the establishment of the University of Bristol and its medical faculty, as related below by Dr. Parker. He had been lecturer on practical physiology, and became professor of pathology in the university, and afterwards of medicine, and the esteem in which he was held by his colleagues is shown by the fact that he was holding the office of pro-Vice-Chancellor at the time of his death.

Dr. Michell Clarke had given special attention to diseases of the nervous system. His Long Fox lecture at Bristol in 1910 was on cerebro-spinal syphilis, and his Bradshaw lecture before the Royal College of Physicians in 1915 was on nervous affections of the sixth and seventh decades of life. He was the author of a work on hysteria and neurasthenia published in 1905, and contributed a number of papers to *Brain* and to our columns, including a case of removal of an intrathecal tumour of the lumbar region of the spinal cord, followed by a remarkable degree of recovery. Dr. Michell Clarke, as Dr. Parker notes, was an active member of the British Medical Association. He was for many years honorary secretary of the Bath and Bristol Branch, and was afterwards its president. He was secretary of the Section of Medicine at the annual meeting in Bristol in 1894, vice-president of the Section of Pathology in 1903, and vice-president of the Section of Medicine in 1912. He was also president in 1909 of the Bristol Medico-Chirurgical Society.

We are indebted to Dr. GEORGE PARKER, his colleague at the General Hospital, for the following tribute to his character and attainments:

The death of Dr. J. Michell Clarke in the full vigour of his powers is an irreparable loss to his numerous friends, to his colleagues, and to the medical profession. In his life I look back on one of the finest characters I have ever met. From the day when, as old Cambridge students, we met trembling on the steps of the College of Surgeons (there was no Joint Board then) to the end of his days he was always the same able, kind-hearted man, with a boundless capacity for work, and a wonderful power of self-restraint and sound judgement.

From his earliest years he had made up his mind to excel in whatever he took up, whether it was science or golf, and to this he added an unwearied industry which made his life a fountain, ever pouring out a full stream of valuable work without a moment's loss. His fellow workers hardly realized the greatness of the output, for it came so regularly and quietly and with so little display of effort through his ceaseless devotion to his duties. As a scientific man he threw himself from the beginning

of his career into the development of neurology, especially on the pathological side. His brilliant and careful work in this department has a permanent value in the great structure which has been raised during the last thirty years. To the last he took the keenest interest in the subject and found time for a steady output of papers and laboratory work of the highest order. But he had endless other duties. He had to take a large share in the changes which led to the Bristol Medical School becoming a faculty of the new university, and here, as in everything else, his clear judgement, his quiet determined energy, and his capacity for grasping a complicated problem were of enormous value.

For the British Medical Association, too, he did yeoman's work. How few consultants there are who have toiled year after year in carrying out the routine work of honorary secretary for a large Branch and the delicate and troublesome duties under an ethical committee in composing local disagreements; and again, in representing on the local Insurance Committee the needs of panel practitioners at a time when party feeling ran high; and finally, as a member of the Central and Local War Committees, in taking on the terribly responsible duty of deciding who could be spared to offer their lives and services. It is to the strain of all these duties in addition to his military functions as Lieutenant-Colonel R.A.M.C.(T.) when in charge of some 1,300 beds in the 2nd Southern General Hospital that we must ascribe the fatal breakdown.

His work at the Bristol General Hospital in Guinea Street, where his father had served before him, was marked by the same thoroughness, punctuality, and breadth of view. Both the lay committee and his colleagues constantly looked to him to grapple with difficulties and to compose differences. For thirty years he showed what excellent work could be done at a voluntary hospital, and his methodical and exact teaching was eagerly sought for by students, who cherish the deepest affection for his memory. He had a large and widely spread practice throughout the West of England, as his high character and scientific attainments were recognized on all hands.

I do not recollect his ever being drawn into an angry discussion. His uniform good temper and quiet determination always enabled him to state his side of a question with clearness and dignity, and an Aristotelian discretion and tact gave weight to his judgements. In his scanty leisure he ever found delight in the best literature, in the pages of Saint Beuve, or in some historical or philosophical writer. In his last illness he pressed upon me a review of McKenna's new work on Plotinus which had charmed him, and nothing gave him more delight than a discussion on such subjects. He bore up bravely under the loss of his second son, who was killed in action, but the strain of the war told upon his keen patriotic feelings. It is difficult to speak of the generous kindness and toil he gave to those in need around him, but it must suffice to say that few men of his time will be more regretted than our good colleague and friend.

HENRY MACNAUGHTON-JONES, M.D., M.Ch., M.A.O.,

F.R.C.S.I. AND EDIN.

DR. HENRY MACNAUGHTON-JONES died on April 26th, at High Barnet, at the age of 73. He was the son of the late William Thomas Jones, M.D., of Cork. He received his education at Queen's College, Cork, where for ten years he was demonstrator and lecturer on anatomy, and subsequently professor of midwifery. He obtained the degrees of M.D. and M.Ch. of Queen's University of Ireland in 1864, the diplomas L.R.C.P.I. and L.A.H. Dubl. in 1865, and F.R.C.S.I. in 1870; in 1886 he was awarded the M.A.O. degree of the Royal University of Ireland (*honoris causa*). After a varied experience of Poor Law dispensary work in the city of Cork, he served for eleven years as physician to the Cork Fever Hospital. During this period of his career he founded the Cork Eye, Ear, and Throat Hospital, and some years later was largely concerned with the foundation of the Women and Children's Hospital, now the Victoria Hospital. Coming to London in 1883, Dr. Macnaughton-Jones devoted himself to obstetrical and gynaecological work, in which he took for many years a prominent position. Among the offices which he held were the presidency of the British Gynaecological

Society and the presidency and vice-presidency of the Obstetrical and Gynaecological Section of the Royal Society of Medicine. He was also an honorary member of the Obstetrical Societies of Leipzig, Munich, Belgium, and Rome, and he was honorary president of the International Obstetrical and Gynaecological Congresses held at Amsterdam, Rome, Paris, and Berlin, and president of the British Section at the Congress at Petrograd. Dr. Macnaughton-Jones was a ready writer and a fluent public speaker. His work on *Diseases of Women*, in two volumes, reached its ninth edition in 1904, and the *Handbook on Diseases of the Ear and Naso-pharynx* passed through six editions. He was one of the founders and an early president of the first Branch of the British Medical Association formed in Ireland. At the annual meeting at Bath, in 1878, he was vice-president of the Section of Obstetric Medicine, and he held the same office two years later at the Cambridge meeting. He was for long one of the leading spirits of the Irish Medical Schools' and Graduates' Association, of which he was thrice president.

By the death of Dr. SEYMOUR H. MUNRO of Nantwich, at the age of 85, a fine example of the old school of country practitioners has passed away. He studied medicine at Edinburgh University, graduating M.D. in 1857, and took the L.R.C.S.E. diploma in the same year. Settling down in practice at Nantwich fifty-three years ago, his great energy and ability soon established his reputation and secured a large practice in the town and neighbourhood, whilst his kindness endeared him to his patients. Outside his profession he threw himself into every phase of public life; every movement likely to promote the welfare of the community or the good of the individual had his whole-hearted support. A lover of country life, an expert judge of horses, he was a familiar figure in the show ground and the sale yard, and his horsemanship is now a tradition amongst the people. He was for many years a justice of peace of the county, and took an active part in all magisterial duties. He leaves a widow, a daughter, and six sons, of whom two are in the profession—Dr. J. D. Munro, who succeeds him, and Dr. Ronald Munro of Northenden. The funeral service bore striking testimony to the esteem and affection in which he was held and the grief felt at his death.

THE LATE MR. GUY ELLISTON.—Mr. George C. Franklin, M.B.E., who was president of the Association when the annual meeting was held in Leicester in 1905, desires to add to the appreciations of Mr. Elliston, published last week, an expression of his recognition of the excellence of the arrangements made by Mr. Elliston for the week's work in Leicester and of his management generally. His loss, Mr. Franklin adds, will be most keenly felt by every member of the British Medical Association who knew him.

The Services.

ROYAL NAVY.

Deputy Inspector-General R. Gavin Brown, R.N., has been awarded a Greenwich Hospital pension of £150 a year in the vacancy caused by the death of Deputy Inspector-General Stephen Sweetman.

INDIAN MEDICAL SERVICE.

Temporary Rules for Accelerated Promotion.

Pending the resumption of normal conditions, the following Rules shall govern the claims of officers of the Indian Medical Service to accelerated promotion:

(i) (a) Officers under twelve years' service at outbreak of war: Those who qualified in part, and those on study leave or combined study leave, who were recalled to duty, shall receive accelerated promotion with pay and position.

(b) Officers who have completed twelve years' service and over at outbreak of war: Those who qualified in part, or who were recalled from study leave or combined study leave, shall receive accelerated promotion with advantages of position but without back pay; provided that in the opinion of the Director-General, Indian Medical Service, such officers produce satisfactory evidence of their intention to have qualified fully before the expiry of sixteen years' service.

(ii) In the case of all other officers, the period within which they are required to qualify for accelerated promotion (that is, while in the rank of captain or within four years of their promotion to the rank of major) shall be extended by a period equivalent to the duration of the

war. Officers qualifying within the latter period shall receive exactly the same concessions as if they had qualified within the prescribed time.

Badges.

The introduction of a collar badge of the following description has been approved of for wear by officers of the Indian Medical Service with the service dress jacket in place of the departmental gorget patches which have been abolished:

Description.—An eight-pointed star encircled by a laurel wreath and surmounted by a Tudor crown. On the star, the garter and motto; within the garter, the rod of Aesculapius with a serpent entwined. Below the star, a scroll inscribed "Indian Medical Service."

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation, held on April 26th, the following medical degrees were conferred:

M.D.—H. F. Marriss.*
M.B., B.C.—R. French.
B.C.—H. W. Hales.*

* Admitted by proxy.

UNIVERSITY OF GLASGOW.

THE degree of M.D. (with commendation) was conferred, on April 23rd, upon Margaret E. Robertson.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At an ordinary comitia on April 25th, when the President, Dr. Norman Moore, was in the chair, the following candidates were admitted as Members of the College:

Wm. John Hart, L.R.C.P.; Helen Ingleby, M.B.Lond., L.R.C.P.; George Carmichael Low, M.D.Edin.; Arthur Lisle Panch, M.B.Lond., L.R.C.P.; Walter Rupert Reynell, M.D.Oxf., L.R.C.P.; George Riddoch, M.D.Aberd.; Adam Niven Robertson, M.D.Edin.; Douglas Robert Chaplin Shephard, M.B.Lond., L.R.C.P.; Erio Wordley, M.B.Camb., L.R.C.P.

The Censors Board recommended that the licence to practise be restored to Mr. Alfred Banks. Licences to practise physio were granted to 101 candidates who had passed the required examinations, having conformed to the by-laws and regulations. The following elections to the Fellowship of the College were made on the nomination of the Council:

Walter Broadbent, M.D.Camb.; Hugh James Moore Playfair, M.D.Lond.; Sydney Walter Curl, M.D.Camb.; Frederick Lucien Golla, M.D.Oxf.; Archibald Montague Henry Gray, M.D.Lond.; Harold Benjamin Day, M.D.Lond.; Alfred Ellington Stansfeld, M.D.Camb.; William Whiteman Carlton Topley, M.B.Camb.; Charles Hubert Bond, M.D.Edin.; Percy William Bassett-Smith, C.B.

Nominated by the Council under By-law LXXI, Regulation 3, and proposed to the College for election to the Fellowship:

Sir Walter Morley Fletcher, M.D.Camb., F.R.S.; Sir George Newman, K.C.B., M.D.Edin.

The President resigned the office of member of the Committee of Management, and appointed Dr. W. Hale White to succeed him. He informed the College of the names of the Fellows nominated to serve on the committee to consider the proposed Ministry of Health.

On the motion of Dr. H. Russell Andrews, it was resolved that a committee be appointed to consider questions arising out of the "twilight sleep" method.

On recommendations of the Committee of Management the Technical Institute, Newport, already recognized for instruction in chemistry and physics, was recognized for instruction in biology; Brighton College was added to the list of schools recognized in chemistry and physics; and the following universities were added to the list of universities whose graduates in medicine are admissible to the final examination of the Examining Board in England, under the conditions of paragraph IV, section 3, of the Regulations, namely: (a) Creighton University, Omaha; (b) Georgetown University, Washington; (c) the University of Maryland and College of Physicians and Surgeons, Baltimore.

In 1915 Gorter and Ten Bokkel Huinink described a method for determining in advance if a given typhoid vaccine would prove protective for man. This consisted in finding that the vaccine would protect guinea-pigs against an intraperitoneal injection of typhoid bacilli that would be fatal to control animals, and was considered to be most satisfactory. But it assumes that what holds true for guinea-pigs can be applied to man, and Aldershoff (*Folia microbiologica*, Delft, 1917, v) has repeated the work on guinea-pigs and investigated its practical application by estimating the agglutinating and bactericidal powers of men inoculated with the vaccine. The object of his research was to find out if in man a vaccine that fulfils the guinea-pig test gives better results than one that fails completely or partially when thus tested; he concludes that the criterion set up by Gorter and Ten Bokkel Huinink cannot be relied on in practice.

Medical News.

THE next session of the General Medical Council will commence at 2 p.m. on Tuesday, May 28th.

MR. CHARLES J. HEATH, F.R.C.S., has been elected President of the Wildfowlers Association of Great Britain and Ireland.

THE annual general meeting of the London and Counties Medical Protection Society will be held at 32, Craven Street, Strand, W.C., on May 15th, at 4 p.m.

MR. CHARLES W. DEAN, F.R.C.S. Edin., surgeon to the Lancaster Royal Infirmary, has been appointed deputy coroner for Lancashire (Lancaster Division).

DR. W. HANDFIELD HASLETT, J.P., C.C., chairman of the South Middlesex Division of the British Medical Association, has been unanimously elected, for the fifth year in succession, chairman of the Sunbury-on-Thames Urban District Council.

SIR A. GRIFFITH-BOSCAWEN has stated that the Insurance Commissioners accept responsibility for cases of tuberculosis in an early stage, but not for those that are far advanced. The Pensions Ministry is making arrangements for the use of annexes to sanatoriums belonging to the Metropolitan Asylums Board in London.

THE Lord Roberts Memorial Fund (122, Brompton Road, S.W.) is giving permanent employment to nearly 1,200 disabled men at its workshops in London and the provinces. A special appeal is to be made in London in the week beginning May 20th for contributions to an extension fund.

THE "Earlsmead" Home of Recovery, Hornsey, providing 35 beds for the use of the Great Northern Central Hospital, was opened on April 30th by Lady Crossfield in the presence of the Mayor of Hornsey, Mr. H. J. Tennant, M.P., deputy chairman of the hospital, and others interested in its welfare, including the donor, Mr. Harrop.

THE Osiris prize of the value of £4,000 was founded for the recognition of the most important discovery or work in science, letters, arts, industries, or generally anything for the public benefit. The prize has been held in abeyance since the beginning of the war, but the Institute of France has decided to make an award this year.

THE report presented to the annual meeting of the Invalid Children's Aid Association stated that during last year 9,185 invalid children had been assisted, of whom 423 had been sent away to convalescence; 584 surgical appliances had been supplied and 211 children apprenticed and trained. Of the £30,707 raised, £7,526 had been collected from parents. Owing to the difficulty of obtaining accommodation at hospitals four new convalescent homes had been opened.

THE committee appointed last October, with Sir George Makins as chairman, to report on the organization and equipment of hospitals for British troops in India, has concluded its labours, but its report has not yet been published. We note, however, that in the Indian Budget for 1918-19 a vote of £200,000 is taken for the introduction of the station hospital system for India and improvements of hospitals.

IN consequence of the passing of the Military Service No. 2 Act, 1918, the Local Government Board and the Secretary for Scotland have issued new regulations which came into operation on May 2nd, 1918. Provisions have been inserted excepting disabled men who have been discharged, and who by reason of the Review of Exceptions Act (now repealed) or of pledges given by the Minister of National Service were not to be called up for service. The members of local tribunals in England and Wales are in future to be appointed by the Local Government Board, and the new regulations provide that the existing tribunals and their members shall be deemed to have been appointed by the Local Government Board. Considerable changes of details are made by the new regulations, the principal object being to accelerate the decisions of cases. The grounds on which exemption may be claimed remain as at present, but the need for men being greater than ever the standard must be stricter. Exemptions must not in future be granted for more than six months, except where the National Service representative otherwise agrees, or in the cases of certificates on the ground of ill health or infirmity or of conscientious objection. Special regulations will be issued relating to applications concerning qualified medical practitioners, and the regulations now issued do not apply to any such applications. It is not necessary for any qualified medical practitioner who wishes to claim exemption to take any action until the special regulations are issued.

Letters, Notes, and Answers.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Attilology, Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL, SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES AND ANSWERS.

C. T. S. wishes to hear of a substitute for glycerin for enemata.

HAY FEVER.

A CORRESPONDENT asks for advice as to some suitable substance with which to spray the nose in severe hay fever. Reference to Sir St. Clair Thomson's recent book on *Diseases of the Nose and Throat* shows that quinine in a spray (gr. j to 3j) or ointment (gr. xxx to 3j of vaseline) has been well reported on, and its employment is so easy that it is worth trying. Dr. Watson-Williams recommends that at the beginning of the hay fever season the nasal passages should receive one spraying with a solution of mercury biniodide (2 to 5 per cent.), the application being preceded by cocaine and followed by a hypodermic injection of morphine. Sir Andrew Clark recommended painting the nasal mucosa with the following: Glycerin of carbolic acid 3j, quinine hydrochloride 3j, mercury perchloride gr. 4. Its use, which should be preceded by the application of cocaine, is often followed by considerable reaction. If necessary it may be repeated on the second to the fourth day, but not more than three applications are required. If any readers can make better suggestions we should be very glad to receive them.

LETTERS, NOTES, ETC.

THE VALUE OF THE WASSERMANN TEST.

DR. A. S. LEYTON (Oxford) writes: A most remarkable factor in the discussion about the value of the so-called "Wassermann test" (it is a bad habit into which we have fallen to label these biological reactions with the names of the alleged inventors, often regardless of historical accuracy) is the unanimity with which the question has been begged, that because the complement deviation test is positive, therefore the case is one of syphilis. A more flagrant example of begging the question has rarely happened in scientific literature. We know much too little about the factors involved in the reaction to make such an assertion, and the result obtained by a positive reaction is in many cases quite as contradictory, from a clinical aspect, as it is in the case of a negative reaction. Personally, I do not regard the complement deviation test as any more pathognomonic than the agglutination test, and I think we should be as slow in diagnosing syphilis on account of a positive complement deviation test as we should in diagnosing typhoid on the result of a positive agglutination test.

DR. H. MILLER GALT, Pathologist, Stephen Rall Memorial Laboratory, Royal Sussex County Hospital, Brighton, makes the following observations in the course of a letter on this subject: Perhaps the commonest error into which the practitioner falls when presented with the results of Wassermann tests is to assume that the results admit of no other interpretation than the words "positive" and "negative" imply. A negative Wassermann reaction does not necessarily prove syphilis absent any more than a positive result proves in all cases its presence. The positive or negative result is simply a link in the chain of evidence; and while its value is usually great, it may actually be misleading in a small proportion of cases. No pathologist claims 100 per cent. of results which are in accordance with the clinical evidence, but the 95 per cent. or so of such results form a most valuable help to diagnosis. The medical officer in charge of the venereal diseases clinic at this hospital informs me that he has never failed to obtain a positive Wassermann reaction where the case was clinically one of syphilitic sore. After discussing possible fallacies in the cases reported by Dr. J. S. Robertson, April 13th (p. 427), Dr. Galt concludes as follows: Certainly a negative Wassermann reaction in a patient as the result of treatment is of slight value as a sign of cure. How many such negative results should be obtained, and over what period, are points still undecided.

DR. JAMES S. ROBERTSON writes with reference to the case mentioned by him in his note on April 13th (p. 427), of the pregnant woman who complained of a small, painless, persistent, slowly-growing vulval "spot," that the pathologist consulted was attached to a large London general hospital; it

was he who, without visual examination, tried to assure her that the test would give the correct answer. I was only asked by a colleague to give the injection, and when I visited her she was in the secondary stage. The question of my ability need not necessarily have arisen, for all the cases had been previously diagnosed, except one, which others had missed. Had the diagnosis not been definite, I do not think I should have wished for a Wassermann test, for even Professor Beattie is not prepared to say that the test is infallible. He says it aids. It aids also to make an indefinite diagnosis more indefinite by its indefiniteness.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

Subscriptions to the Second Appeal.

Subscriptions to the Fund should be sent to the Treasurer, Dr. H. A. Des Vaux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

MEDICAL STUDENTS AND MILITARY SERVICE.

PERPLEXED writes: I am afraid, when the fact becomes generally known, as it undoubtedly will be, that the passing of the first medical examination releases a man from army service, that the entrance to our profession may become a shelter for slackers. The following case, however, I think deserves passing notice: Graded A.1, and called up at the age of 19, having just passed his first medical examination. Joining an O.T.C., he in due course obtained a commission. After receiving £50 kit allowance from a generous Government, and having completed twelve months' pleasant training in England, now, when the call for men is urgent and the age limit is being raised, he is released at the age of 20 in order to resume—should I say commence?—his medical studies, still holding his commission as second lieutenant and wearing khaki.

** The matter appears to be governed by National Service Instruction No. 35 of 1918, dated March 5th, 1918, and entitled "Protection from Military Service of Medical Students." It provides *inter alia* that a medical student who at the date of the instruction was a full-time student of a recognized medical school and had passed his first professional examination in chemistry, physics, and biology (or botany and zoology) for his degree or licence, is not, subject to provisions in later paragraphs, to be called up, whatever his medical category or grade, so long as he remains a full-time medical student. One of these provisions is that he must pass his professional examination in anatomy and physiology within thirty-six months of the date of commencing his professional studies; another, that if he is delaying his qualification unnecessarily or otherwise not satisfactorily pursuing his medical studies, the case is to be referred to the Director of National Service for the region. A third proviso is that the student must, if requested, offer his services as a surgeon probationer in the navy. It is probable that in a case such as that quoted by our correspondent this call will come within eighteen months.

CO-OPERATION I

PUBLIC VACCINATOR writes: There is, I understand, a shortage of army doctors, and the co-operation of civilian doctors is requested. In January of this year, being public vaccinator, I vaccinated a prospective cadet with Government lymph in four places, all of which took, and presumably the marks remain. I then inoculated him with 1,000 and 2,000 million typhoid vaccine, keeping him in bed on one day on each occasion. He has joined up and is told "that the vaccination and inoculation of civilian doctors cannot be recognized, and he must be done again"!

LESIONS OF PERIPHERAL NERVES: ERRATUM.

In the report of a paper read by Captain C. B. Alexander before the recent Neurological Congress at Alder Hey Hospital, which appeared in the JOURNAL of March 30th, two decimal points were omitted. In the table showing the relative frequency with which various peripheral nerves were involved (p. 381): Radial 25 per cent., and posterior interosseous 25 per cent. should both be 2.5 per cent.

LECTURES AND DISCUSSIONS.

The course of public lectures on biological problems of to-day will be resumed at University College on Monday next at 5 p.m., when Major Martin Flack, R.A.M.C., will speak on the physiological aspects of flying. On the following Monday Dr. H. H. Vernon, of Oxford, will speak on industrial efficiency and fatigue. The fifth course of lectures on public health problems under war and after war conditions was resumed last Wednesday at the Royal Institute of Public Health (37, Russell Street, W.C.) by Sir James Cantlie, who spoke on ambulance work. Professor Bayliss will deal with accessory components of food on Wednesday, May 15th, at 4 p.m. At a meeting of the Royal Sanitary Institute, at Hereford, on May 10th, at 5 p.m., Dr. D. Gold, M.O.H. Herefordshire, will open a discussion on tuberculosis.

The following appointment of certifying factory surgeon is vacant: Tunstall (Stafford).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

				£	s.	d.
Seven lines and under	0	6 0
Each additional line	0	0 9
Whole single column	4	0 0
Whole page	12	0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE PROPHYLACTIC USE OF QUININE IN MALARIA:

WITH SPECIAL REFERENCE TO EXPERIENCES
IN MACEDONIA.

BY

C. H. TREADGOLD, M.A., M.D.CAMB., D.T.M.PARIS,
CAPTAIN R.A.M.C.

BETWEEN the beginning of February and the end of April, 1917, I examined the various units of a certain division in Macedonia with a view to determining the proportion of men on duty who were infected with malaria. Smears from 540 men were stained and searched for parasites, and the results are summarized in Table I. Plasmodia were found in over 30 per cent. of the men who had been in Macedonia during the previous summer, while the altered differential leucocyte count suggested that over 60 per cent. of such men were in reality infected. Had it been possible to reckon the absentees in the Malta and Salonica hospitals, the total percentage of infected men would of course have been much greater. Parasites were found in nearly 8 per cent. of men with no history of fever; if we regard the increased hyaline count as evidence of infection, their number increases to over 37 per cent.

As no evidence of infection was found in recent drafts, it may be assumed that the great majority, if not all the men in whom parasites were present, had been infected during 1916 or earlier.

Technicalities.—The average time spent over each slide was about ten minutes, and no man's blood was examined more than once. Gametes were found in over 90 per cent. of the positive slides, and schizonts were also present in a large proportion. *P. vivax* was the common parasite found; *P. falciparum* was noticed on seven occasions, *P. vivax* being also present in four out of the seven; *P. malariae* was only diagnosed once. To simplify matters, *P. falciparum* and *P. malariae* have been reckoned in the table as *P. vivax*.

TABLE I.

Groups I to III are comprised of men who were in Macedonia during the summer of 1916; Group IV of drafts reaching Macedonia between September 1st and December 31st, 1916; and Group V of drafts reaching Macedonia in 1917. Members of the last two groups had never before been out of Britain.

Group.	Total Examined.	<i>P. vivax</i> Present.	Hyaline Leucocytes.*	
				Increasing presumably infected to
I. Fever within 3 months of examination	300	120=40%	89	69.6%
II. Fever during summer, but none within 3 months of examination	93	16=17.2%	33	52.6%
III. No history of fever ...	63	5=7.9%	20	39.6%
IV. No history of fever ...	40	3=7.5%	11	35.0%
V. No history of fever ...	44	—		

*15 per cent. or over in men in whom no parasites were found.

The Results of Quinine Prophylaxis.

By quinine prophylaxis is meant the regular administration of quinine with a view to preventing the development or recrudescence of clinical malaria.

Method of Administration.—The salt employed was the sulphate, shown by analysis to be pure; the daily dose (gr. v-xxx) was given either in acid solution or in tablets.

The men in Groups I, II, and III of Table I had been taking quinine during the greater part of 1916, and I was assured by the regimental medical officers that many were taking it at the time I made the blood films. The kind of evidence available is illustrated by a group of twelve men belonging to the same brigade, the majority to a regiment whose medical officer had had considerable experience of malaria in the East, and who was positive that the prescribed dose was being taken; all the men had been taking daily doses of quinine varying from 30 to 10 grains. The length of time since the last relapse varied from eight days to three months. There was tinnitus and deafness in

three cases (one taking 30 and two taking 10 grains daily), and deafness in three cases (one taking 30 and two 10 grains daily). In all the 12 cases *vivax* schizonts and gametes were present in the peripheral circulation.

Owing to the varying amounts of quinine ordered by the medical officers attached to the different regiments it was possible to place 125 out of the 150 men examined during February into one or other of the following groups (Table II). Whether the quinine was given in small or large doses or not at all, seemed to make little difference either to the number of relapses or to the proportion of cases in which parasites were found; many of these men were constantly relapsing.

TABLE II.

Groups.	No. of Cases Examined.	No. of Men in Whom Parasites were Found.
I. No quinine between attacks ...	26	16 = 61.5 %
II. 30 gr. daily ...	21	11 = 50.2 %
III. 20 gr. daily ...	9	6 = 66.6 %
IV. 15 gr. daily ...	6	4 = 66.6 %
V. 10 gr. daily ...	48	22 = 45.8 %
VI. 15 to 30 gr. biweekly ...	11	3 = 27.2 %
VII. 6 gr. daily and 12 gr. biweekly ...	4	3 = 75.0 %

The evidence so far considered indicates (1) that, despite infection, a fair proportion of men examined had, temporarily at any rate, resisted illness or got the upper hand of the disease. (2) That a great deal of sickness due to malaria nevertheless existed in the division, much of it being little influenced by the administration of quinine.

The figures available from French sources show an even higher degree of infection. For example, Garin¹ claims that plasmodia (usually gametes) can be found in the blood of from 60 to 80 per cent. of troops returning from Macedonia without a history of malaria, while Abrami² states that from 85 to 95 per cent. of the French Macedonian army was attacked by malaria in spite of early and general preventive quinization! An early and correct solution of the following problems is therefore urgently needed:

I. Is any appreciable proportion of the Macedonian force saved illness through the administration of prophylactic quinine? If so, what proportion?

II. Is the general course of the disease ever affected by the previous administration of prophylactic quinine? If so, is the sum of such influences favourable or the reverse?

To answer these questions demands an exact knowledge of the conditions upon which the usefulness of the drug, both as a prophylactic and as a curative agent, depends. Unfortunately these conditions have never been thoroughly investigated on scientific lines, and large gaps in our knowledge exist. In spite of these drawbacks I have been tempted to analyse and draw conclusions from the data available in the literature of the subject.

I.—WHAT PROPORTION OF THE MACEDONIAN FORCE IS SAVED ILLNESS THROUGH THE PROPHYLACTIC ADMINISTRATION OF QUININE?

A. General Considerations and Analysis of Statistical Evidence.

Altogether I had access to some two hundred original articles, reports of medical societies, etc., in which the question of quinine prophylaxis was either dealt with or discussed. Nearly all of them were written in English, French, or German, and all—with one exception—were published between the discovery of the malaria parasite in 1880 and the present time. Of the authors 52.2 per cent. gave no details of their personal experience, while only 16.9 per cent. made use of controls. Table III gives an idea of the opinions expressed by these different writers, no less than 80 per cent. of whom were in favour of quinine prophylaxis.

TABLE III.—Views of Writers on Quinine Prophylaxis.

	In Favour of Quinine.	In Favour of Quinine with Reservations.	Against.	Total.
No statistics	65	21	20	106
cs but no controls	43	6	12	61
cs with controls...	26	0	8	34
Total	134	27	40	201

The majority of these papers were, however, devoid of interest. No doubt a large number of writers were unfavourably influenced by the difficulties in the way of controlling their results, and realized the impossibility of appreciably increasing our knowledge in the absence of such controls; be this as it may, the difficulties in the way of experimental research have unfortunately brought extremists to the fore, and such statements as the following are scattered throughout the literature:

The whole trend of recent inquiry and the results of clinical experiment have been to show that at the present day, more than ever before, the scientific administration of quinine is established as a measure of very great value and that it is indispensable in the general prevention of the disease.*

Quinine has its position in relief and cure, but in sanitary administration it has none.⁴

Knowing as we do that resistance to malarial disease is considerably greater in the inhabitants of malarial countries than it is in immigrants from non-malarial ones, it would seem natural to suppose that, other things being equal, the benefit derived from the use of prophylactic quinine varies directly as the resistance of the individual taking it—in other words, the greater the resistance the better the statistics. The truth of this supposition can only be tested in the present state of our knowledge by analysing the statistical evidence from different countries, taking care to distinguish between the natives of such countries and immigrants.* This has been accordingly done in Tables IV to VII.

TABLE IV.—Countries bordering on Mediterranean Basin.

	Statistics but no Controls.	Statistics with Controls.
In favour of quinine	16 ...	18
In favour of quinine with reservations	0 ...	0
Against	1 ...	0
Total	17 ...	18

All thirty-four papers in favour of quinine prophylaxis deal with the question in so far as it affects the permanent inhabitants of the respective countries; the single paper against deals with temporary inhabitants—namely, the French army in Macedonia.

TABLE V.—Africa excluding the Mediterranean Area.

	Statistics but no Controls.	Statistics with Controls.
In favour of quinine	13 ...	2
In favour of quinine with reservations	1 ...	0
Against	3 ...	2
Total	17 ...	4

One of the four papers in which controls were used deals with natives and is in favour of quinine prophylaxis; the remaining three deal with immigrant whites, one paper being in favour and two against.

TABLE VI.—Southern Asia.

	Statistics but no Controls.	Statistics with Controls.
In favour of quinine	14 ...	5
In favour of quinine with reservations	1 ...	0
Against	6 ...	4
Total	21 ...	9

Three out of the nine papers in which controls were used deal with natives, and are in favour of quinine prophylaxis. The remaining six deal either with immigrants or with partly immigrant populations, such as coolies on rubber plantations; two were in favour of quinine prophylaxis, four against.

* The full bibliography of the authors whose views are summarized in Tables IV to VII will be published in the *Journal of the Royal Army Medical Corps* for June.

TABLE VII.—North and South America, including West Indies.

	Statistics but no Controls.	Statistics with Controls.
In favour of quinine	3 ...	1
In favour of quinine with reservations	3 ...	0
Against	1 ...	2
Total	7 ...	3

One out of the three papers in which controls were used deals with natives, and is in favour of quinine prophylaxis; the other two deal with immigrants, and are against.

A study of these tables reveals the existence of a state of affairs very different from what might have been anticipated from merely glancing over the opinions of the various writers summarized in Table III, especially when we remember that controlled results are the only results of any scientific value. When controls were used and natives of the respective countries investigated, no less than twenty-three, or 100 per cent. of workers, were in favour of prophylactic quinine. When controls were used and immigrants dealt with, only three out of eleven, or 27.2 per cent., were in its favour. The evidence available would therefore seem to justify the enunciation of the following conclusion: "Other things being equal, the natives of malarial districts derive more benefit from quinine prophylaxis than immigrants from non-malarial ones."

Value of Prophylactic Quinine to the Natives of Malarial Countries in the Mediterranean Area.

We have seen that all the available statistical evidence is in favour of administering prophylactic quinine to the inhabitants of Mediterranean districts in which malaria is endemic. What does this really amount to? Celli, one of the best known of the Italian workers, thus expresses himself:

The daily use of quinine is as necessary as daily bread during certain months.⁵

He who takes quinine every day, and therefore has always a supply of quinine in the blood stream, can undergo with impunity inoculations of blood full of malarial parasites, and can expose himself with little or no danger to the bites of infected mosquitoes.⁶

Yet at a later date the following analysis of very extensive clinical material was published by the same author.⁷

TABLE VIII.—Quinine and Mosquito Prophylaxis (Celli).

Mosquito prophylaxis plus quinine prophylaxis	Symptoms in 1.75 % = 1 in 57.
Mosquito prophylaxis only...	Symptoms in 2.5 % = 1 in 40.
Quinine prophylaxis only ...	Symptoms in 20 % = 1 in 5.
No protection	Symptoms in 33 % = 1 in 3.

Clearly the quinine given produced some effect, but compared with the results obtained by mosquito prophylaxis, its action was almost negligible.

The brothers Sergent, who have investigated the subject for many years in Algeria, seem less enthusiastic than they used to be. The last paper I have seen gives details of the quinine given to native children in 1910.⁸ One of their tables is reproduced, and the authors content themselves with the observation that all methods give appreciable results.

TABLE IX.—Quinine Prophylaxis with Controls (Ed. and E. Sergent).

Dose of Quinine.	Improvement.	No Change.	Worse.
0.2 gram daily	19 = 5.5 %	315 = 83.5 %	7 = 2.02 %
0.6 gram every 3 days ...	19 = 4.2 %	425 = 94.6 %	4 = 0.9 %
0.6 gram every 6 days ...	35 = 9.7 %	300 = 80.4 %	16 = 4.8 %
Controls (no quinine) ...	6 = 0.8 %	220 = 90.5 %	21 = 8.7 %

These Italian and North African results are not very impressive, especially when it be remembered that we are dealing with the only type of case in which a consideration of the general statistical evidence led us to suppose that really striking benefit would be uniformly attained—namely, natives who have presumably inherited and acquired a certain amount of immunity against the parasites of their own country.

B. Methods of Giving Prophylactic Quinine.

The two methods usually employed are: (1) A small daily dose (5 grains, for example); (2) a larger quantity (usually 15 grains, taken on two consecutive days at intervals of from a week to ten days).

The advocates of the first method claim that quinine taken in this way is always circulating in the blood, and object to the other because it leaves the individual defenceless for several days owing to the rapid excretion of the quinine absorbed. The partisans of the second method maintain that by giving quinine in this manner the curative effect of the drug is not interfered with, but that the use of the first method may lead to the production of quinine-proof strains of parasites. I have searched the literature, but can find no evidence of one method having any appreciable advantage over the other.

In Italy, Greece, and North Africa, 3 to 6 grains daily is the ordinary dose, and larger quantities are not usually supposed to give any better results. It is seen from Table II that, on the whole, the smallest percentage of cases was diagnosed in those who were taking least quinine. The possible significance of these facts will be considered later.

C. "Suggestion" in Quinine Prophylaxis.

In quinine prophylaxis, as in all forms of medical treatment, the personality of the physician is not without influence, while the extent of his confidence in the treatment proposed can usually be gauged by the patient with considerable accuracy.

Laveran,⁹ in his book on malaria, published in 1898, comments on the fact that the English, who previously wrote so much in favour of prophylactic quinine, seem to have got tired of it. The psychological aspect of malaria prophylaxis has received considerable attention from American writers, several of whom regard the co-operation of the public as essential, and agree that no means of stimulating its curiosity and of keeping its sympathy should be neglected.^{10, 11} In Macedonia the French authorities advertise the merits of quinine by means of humorous coloured posters and picture post cards, which must go far towards reconciling the *poilu* to his daily dose. In Algeria the brothers Sergent have initiated the use of pink tablets containing three parts of sugar and two of quinine bilydrochloride, and state that these are everywhere accepted by the natives with the greatest alacrity, in marked contrast to their attitude towards the classical method. The striking possibilities of suggestion are vividly brought home by the following incident, related in all seriousness by Henrot.¹²

Dr. Nonat, head of the military hospital, Calcutta, was consulted by the Governor of Bengal as to the best way of protecting messengers against malaria. So many died from pernicious malaria as a result of the unhealthy country they had to cross that messengers had become unobtainable. Dr. Nonat, acting on a theory prevalent at the time—that infection took place via the respiratory tract—constructed respirators containing finely divided animal charcoal, and made the messengers wear them; the effect was excellent, for the messengers, although taking exactly the same route as their predecessors, ceased being ill.

D. Conclusions as to the Effect of Quinine in Preventing Clinical Malaria in Macedonia.

1. *Primary Malaria.*—From Table I it is seen that some of the men exposed to the risk of infection escaped, evidently because: (a) They had never been bitten by infected mosquitoes; or (b) if infected, their powers of resistance were equal to the occasion, and no clinical symptoms ensued. If it be asked to what extent the natural resistance of these latter had been reinforced by taking quinine, the answer is that although the drug must have been the decisive factor in a few cases, the evidence points to their number having been very limited. No matter what disease we take, a proportion of any population is always more or less refractory. Moreover, malaria may be a very chronic condition, and the presence of parasites in the blood of people who have never developed symptoms and who have never taken quinine is well known. As Bass¹³ says: "No doubt many people get infected without ever knowing anything about it; others infected under similar conditions may be ill, and in some cases die." Further, the absence of symptoms in such apyrexial carriers is no guarantee of permanent immunity; in many cases all that is needed to produce an attack is such slight lowering

of vitality as is produced, for example, by a chill, a surgical operation, or a broken bone.

2. *Recurrent Malaria.*—I have come across no evidence which leads me to suppose that quinine is any more efficient in preventing relapse than it is in aborting the initial attack (see Table II).

II.—IS THE GENERAL COURSE OF THE DISEASE EVER AFFECTED BY PREVIOUS QUININE PROPHYLAXIS?

A. The Clinical Evidence and Its Significance.

The following examples are taken from the literature of the subject:

1. Celli states that both doctors and patients are unanimous that daily prophylactic quinine very frequently aborts primary infections, notably diminishes relapses, and prevents cachexia.¹⁴

2. So far back as the American civil war the responsible medical authorities¹⁵ state that men were saved from attack and preserved in perfect health for the time being by the use of prophylactic quinine, but that the method was abandoned owing to the shortage of quinine and to the eventual sickness of such men.

3. Neiva (Brazil), who was in charge of 3,000 men in a highly malarial district, found that to obtain the same therapeutic effect the dose of quinine had to be increased in proportion to the length of exposure to infection.¹⁶

4. Bell (Panama) states that men who were receiving the drug, in comparison with those who were not, under otherwise identical conditions, furnished fewer cases in the proportion of three to four; that such men were, however, more refractory to treatment, had a more prolonged convalescence, and relapsed more frequently.¹⁷

5. Stitt¹⁸ is of the opinion that quinine in reasonable doses has little or no effect, while those who take it are less amenable to its curative action, and relapse more frequently than those who only take the drug at the time of an attack; he also maintains that quinine prophylaxis does not prevent either anaemia or splenic enlargement, while Jacobson¹⁹ goes so far as to say that although symptoms may be masked for a time, the actual damage is as great as though no quinine had been given.

6. We have seen that in Macedonia quinine alone is quite unable to prevent malaria, while very large doses have to be given in many cases to obtain clinical amelioration. Only a few weeks ago, at a meeting of the Society of Tropical Medicine and Hygiene, a paper was read by Sir Ronald Ross in which details were given of various intensive forms of quinine treatment in chronic cases of malaria invalided from Macedonia. No matter how high the dose or what route was chosen for its administration, frequent relapses still occurred.

After studying this and similar evidence, we are bound to admit that the general course of the disease may be adversely influenced by the previous taking of quinine.

Why does Quinine give Variable Clinical Results?

In ordinary circumstances the key to the problem undoubtedly lies in the constitution of the patient and in his state of health both at the time of infection and subsequently. Under good social conditions intermittent malaria tends to cure itself both temporarily and permanently, and whether quinine be given or not the temperature returns to normal in a few days. If only a little outside help is required to change the balance in favour of the patient, good hygienic conditions, an enthusiastic physician, and a little quinine will suffice either definitely to cure the individual or, at any rate, to prevent his relapsing for a considerable time in the absence of reinfection. If, on the other hand, the resistance of the patient falls short of this, no marked benefit will result.

Clinical evidence favours the view that the course of malaria may be unfavourably affected by the previous taking of quinine, but we have seen that under relatively favourable conditions a small daily dose of quinine tends to prevent clinical malaria, or at all events to lengthen the incubation period. This, however, cuts both ways, and should an individual run the risk of being frequently infected, the tendency will be for him to receive more massive doses of sporozoites as the result of taking prophylactic quinine. Can we wonder if his malaria is of a severer type when it does develop? It is universally assumed that the sporozoites resulting from conjugation in the insect host possess a greater potential capacity for mischief in the vertebrate host than merozoites derived from many generations of asexual multiplication. A European in the tropics who stays out at night and is generally careless with regard to mosquito prophylaxis is much more likely to suffer from, and to be eventually invalidated home with, chronic malaria than the individual who is careful in these respects. Experiments on protozoa

infections in sparrows are said to show that the severity of the disease largely depends on the dose, that is to say, on the number of sporozoites inoculated.²⁰

We are now in a position to appreciate the inadvisability of giving prophylactic quinine over long periods, and to realize that the severity of malaria in Macedonia has been increased in some cases by previous quinine prophylaxis.

B. The Probable Mode of Action of Quinine in Malaria.

1. As a Prophylactic.—Cushny says:

Quinine differs from most other important alkaloids in acting, not on some specialized form of living matter, but on the general nutrition of almost all forms of protoplasm. Experimental evidence indicates that a number of ferments act more vigorously in very dilute solutions of quinine, while their action is retarded by larger quantities.²¹

It is possible, therefore, that the lytic action of human plasma on malarial parasites is increased when quinine is present in suitable concentration. It is equally possible that too great a concentration of quinine retards this activity; also that the long-continued administration of the drug sets up a tolerance to its presence which necessitates an increase of concentration to get the original effect.

We have previously noted that certain doctors in Mediterranean countries regard 0.2 gram (about 3 grains) daily as sufficient; the few cases I had the opportunity of examining in Macedonia appeared to justify the view that a maximum daily dose for prophylactic quinine exists, and that it is not a very big one. It is also possible that the mechanism about to be considered is not without influence.

2. *The Action of Quinine as a Curative Agent.*—Barlow, as the result of experimental work, thinks that quinine in therapeutic doses does not directly destroy the plasmodium, but tends to poison infected red blood corpuscles in such a way that they are more easily acted upon by the excretory products of the parasite. This results in its liberation before segmentation has taken place and facilitates its destruction. Gametes escape because their less active metabolism does not liberate sufficient toxin to destroy even the quinine-poisoned cell.²²

This explanation is in harmony with the facts. We know, for example, that quinine, given at the beginning of an attack of intermittent malaria, does not appreciably influence the train of clinical events, but tends to prevent subsequent attacks. It would seem to do this by poisoning infected red corpuscles and accelerating their disintegration, thus making the conditions less favourable for the multiplication of the parasite, which is unlikely to be present in sufficient numbers to produce symptoms when the next attack is due. This would give the resisting powers of the individual time to rally. Should his vitality be insufficient to dispose of all the plasmodia the metabolism of the survivors may be assumed to slow down, and even very large doses of quinine may be unable to poison the red cells sufficiently for the parasitic toxins to destroy them with sufficient speed, the plasmodium reacting by slowing its metabolism still further. In many cases it successfully avoids extermination, and, in the event of the host's vitality being sufficiently lowered, a relapse occurs.

In severe and chronic cases resulting either from massive infection or from the feeble resisting power of the individual, or from a combination of the two, large doses of quinine are usually given over long periods; according to the above theory, the poor results obtained would be largely due to an increased tolerance of the red cells for quinine.

Both clinical and theoretical considerations compel us to admit that the general course of the disease may be noticeably affected by the previous taking of quinine, and that the sum of such influences is frequently unfavourable. So far as the allied armies in Macedonia are concerned, there is every reason to suppose that quinine taken daily over periods of many months has increased the severity and chronicity of the disease in a certain proportion of cases. Taking one thing with another, the available evidence indicates that in Macedonia, at any rate, the disadvantages of quinine prophylaxis outweigh the advantages.

GENERAL SUMMARY OF CONCLUSIONS.

1. Small doses of prophylactic quinine—not too long continued—are of proved utility to the natives of malarial

countries, both in the absence of antimosquito measures, and when such measures are incomplete.

2. Quinine may be given with advantage to immigrants under the following conditions:

(a) During short journeys when conditions with regard to mosquito prophylaxis are less favourable than usual.

(b) An occasional dose after an unusually tiring day.

(c) Nervous people may be advised to take an occasional course as an additional precaution in spite of efficient mosquito prophylaxis.

Speaking generally, it may be stated that quinine prophylaxis is usually a bad investment for immigrants in the absence of protection against mosquito bites; taking one thing with another, the practice would in their case seem to be little more than a pious fraud, which has been perpetuated from one generation to the next simply because public opinion throughout the world has never been sufficiently enlightened to encourage the working out of the problem on scientific lines. A few well-planned experiments, carefully and simultaneously conducted in several countries, and these conclusions might have been reached many years ago. We know the experimental method to be at the bottom of all scientific and industrial progress, yet we refuse to admit its very obvious utility in preventive medicine. The following observation applies only too literally to the subject under discussion: "En dehors des sujets dont le contrôle expérimentale est facile, bien peu d'opinions s'appuient sur la logique rationnelle. Sur l'interprétation de faits au fond assez clairs, mais que n'étaient pas des expériences suffisamment tangibles, le désaccord est complet."²³ Surely this lamentable state of affairs cannot continue much longer. The experimental evidence exists, but unfortunately its neglected fragments lie embedded in a very extensive literature, much of which is of little value owing to lack of detail and to the impressions of the writers being uncontrolled by clinical experiment.

APPENDIX.

Although the difficulties in the way of efficient mosquito prophylaxis in non-immune armies operating in highly malarial countries are very great, the failure of quinine prophylaxis shows that more serious efforts must be made to overcome them. A few methods of procedure are therefore mentioned, and their value briefly discussed.

A. The Destruction of Mosquito Larvae.

1. *Subsoil Drainage.*—This is the ideal method, but finance and labour difficulties militate against its general adoption. In Panama, where both money and labour were available, this method was little used, because the engineering works constantly interfered with the drains.²⁴

2. *The Oiling of Surface Water.*—In Panama the system of oiling seems to have been perfect, the whole area for about half a mile round all dwelling places being oiled once a week so thoroughly that all mosquito larvae were killed.²⁴ The method is obviously good when sufficient oil can be obtained.

3. *The Piping of Streams.*—In ravine country, when mosquitoes breed in the pools associated with fast running but temporary streams, such streams may be piped with advantage within half a mile of camps.

B. Mechanical Prophylaxis against Mosquito Bites.

In countries where the reduction of mosquito larvae is difficult the importance of mechanical prophylaxis can hardly be exaggerated. The question will be briefly considered under the following headings:

1. *The Screening of Dwellings.*—In the canal zone all houses occupied by Americans had double doors, the windows being protected with copper-bronze screens—18 mesh to the inch. Orenstein²⁵ concludes that properly screened dwellings alone can be depended upon to reduce by at least one-third the malaria incidence in a locality where malaria is endemic.

2. *Net Prophylaxis.*—Stott²⁶ and others have emphasized the great value of supervised net prophylaxis for soldiers.

3. *Veils and Gloves with Gauntlets.*—These have been employed on sentry duty, etc. If properly used, such methods should be fairly effective, but adequate supervision is obviously difficult or impossible.

4. *Essential Oils.*—Oil of citronella, etc., either pure or in the form of ointment, has been tried for men on night duty, but without much success. According to Celli and others, such methods have a very restricted action.

5. *Night Work.*—The employment of African or Greek troops for sentry duty and all forms of night work during the summer and autumn months would seem to be worthy of serious consideration. After going carefully into the matter, the advantages might be found to outweigh the disadvantages.

6. *Education*.—The last, but certainly not least important, method is the education of officers and men as to the habits of the mosquito and the means of avoiding infection. Pamphlets, posters, lectures, lantern slides, cinema films, all have their place according to circumstance and opportunity.

In conclusion, I should like to thank my brother, Captain H. A. Treadgold, R.A.M.C., for valuable assistance.

INTERLOBAR EMPYEMA AND OTHER SURGICAL COMPLICATIONS OF THE THORAX.*

BY

WALTER BROADBENT, M.A., M.D., F.R.C.P.,

MAJOR R.A.M.C.T.,

PHYSICIAN TO THE ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

EMPYEMA is the commonest complication in the thorax needing surgical treatment. In most cases it is quite easy to diagnose, as it occurs after pneumonia; an increasing rise of evening temperature, with morning remissions and dullness and silence at the base of the lung, with displacement of the heart, pointing definitely to it; but, in quite a number of cases, matters are not so simple.

In rare instances there is no history of pneumonia. This is more common in poor children with bad mothers. I can recollect instances of children being brought to the outpatient department with a chest half full of pus who have not been a day in bed. They have had a cough for some time, are short of breath, and have lost flesh. I have never seen it in better class children.

In an adult it is very rare. About five years ago I was asked to see a shopkeeper's wife who for some weeks had had night sweats, with a temperature of about 100° F. each night and 97° in the mornings. There had been no acute illness, and there was very little cough and no sputum. The suggested diagnosis was phthisis, but no physical signs had been found. The upper lungs were normal, but there was dullness and silence below the angle of the right scapula, and the heart was slightly displaced to the left. My diagnosis was pleural effusion, probably tuberculous, but on inserting a needle pus was found.

Difficulties may occur from the situation of an empyema; it is not altogether uncommon between the lobes of the lungs, where it is often undiagnosed. If untreated such an empyema may burst into a bronchus, and after weeks of coughing, sometimes of fetid sputum, may clear up, or chronic bronchiectasis may result.

CASE I.

A man, aged 47, was admitted under me this spring. He had had left-sided pneumonia six or seven months before, but had recovered and been working at Newhaven until shortly before admission. He had a severe cough and a good deal of expectoration; the temperature was 100° at night. There was dullness in the second and third right spaces in front and diminished resonance below; bronchial breathing at the apex, distant tubular breathing in the second and third spaces, weak breathing below, with coarse crepitations. Over the right back breathing was bronchial and rather weak in the upper half, but there was no dullness. The left chest was normal except for some rhonchi.

The previous pneumonia had been on the left side and was too long ago to count, but I thought the case was one of interlobar empyema. A needle was introduced in the second space, over the dull area, that afternoon without getting pus.

Owing to an attack of influenza I did not go up to the hospital again for a fortnight; by that time Captain Prowse had examined the man with x rays, and reported a large abscess cavity in the upper part of the right side of the thorax rather more than half filled with fluid, on which waves could be seen when the man was shaken. In the meantime the patient was coughing up large quantities of sputum, and, when I saw him again, all dullness had disappeared and breath sounds were almost normal over the right upper chest. He had coughed up the whole empyema.

These interlobar empyemata may burst into the general pleural cavity. Of this I have seen three cases.

CASE II.

A youth, aged about 18, had a very severe pneumonia, implicating both lobes of the left lung and part of the lower lobe of the right. His temperature came down gradually for ten days, and then began to rise in a hectic manner. The left chest remained dull, but tubular breathing and crepitations could be heard all over. I could not detect any special dullness over the interlobar area. One day his temperature and pulse-rate both fell and he said he felt better, but I was surprised to find a large area of absolute dullness and silence at the left base, where the day before had been breath sounds. On putting in a needle pus was found, and at the operation there was a good pint of it. I believe that his empyema was originally interlobar, and, when it burst into the general pleural cavity, the relief of tension caused the fall of pulse-rate and temperature.

CASE III.

A soldier, admitted under me last autumn with dullness from the spine of the left scapula down to the base. A needle drew off pus. Major Buck operated in the usual situation and found very little pus. A few days later the temperature was still high and the man was worse. I then found that the lower part of the back was slightly resonant, but just below the level of the spine of the scapula there was an area of absolute dullness about three inches in depth. An aspirator inserted here withdrew much pus, which, however, reaccumulated, and Major Buck removed a portion of the fourth rib between the scapula and the spine, and opened a large empyema between the upper and middle lobes of the lung. The operation was one of some difficulty owing to the depth of muscle. In this case the original empyema was evidently interlobar and some of the pus had leaked down over the lower lobe, where it was found at the first operation.

CASE IV.

In this case an operation for empyema of the right side of the chest in a child set free only a very small quantity of pus, but a few hours later a sudden gush of quite half a pint of pus soaked the dressings. This must have come from between the lobes.

My father, Sir William Broadbent, described three cases of interlobar empyema in the *Practitioner* in 1905.

In the first pus made its way to the surface above and just outside the left mamma, and the patient made a good recovery.

In the second several unsuccessful aspirations had been made in the lower part of the right chest before he saw the case. It had been noted that breath sounds could sometimes be heard lower on the right front one day than the day before. This led him to suspect interlobar empyema. He found a band of dullness above the spine of the scapula and in the apex of the axilla. Pus was found on passing in a needle high up in the axilla. A piece of rib was removed in this situation, and half a pint of pus was evacuated, with rapid recovery.

The third was a boy, aged 10, who had a left-sided influenzal pneumonia spreading from base to apex. After a crisis on the ninth day, the temperature assumed a suppurative type. The doctor, finding dullness on the whole left base up to the spine of the scapula, absence of vocal fremitus and marked oegophony, put in a needle in three different places, but without success. He noted that the upper part of the lung was becoming duller and more silent. When seen by my father there was absolute dullness with no vocal fremitus or resonance or breath sounds from the apex down to the fourth space, whereas the lower part of the chest in front was comparatively resonant. At his suggestion a needle was put in at the lower edge of the pectoralis with the arm at right angles to the chest. A whole pint of pus was withdrawn. After operation at the site of puncture, a large collection of sloughs came away, and the boy ultimately made a good recovery.

When much pus collects in an interlobar fissure the lower lobe of the lung is so compressed that it becomes dull and airless, leading to the belief that there is an ordinary empyema, until exploration in the usual areas finds no pus. In the last case mentioned both upper and lower lobes were so compressed.

The characteristic of interlobar empyema appears to be a very dull band, either in the second and third spaces in front or just below the spine of the scapula behind. As a rule, there is much diminished resonance over the lower part of the chest, but not the flat dullness of the band of fluid, and breath sounds are very weak and usually absent at the base. The best place to insert a needle is the

* Read before the Medical Society of London.

second or third space in the anterior axillary region, with the arm extended above the head.

Even clear fluid may be confined between the lobes. Quite recently I saw a child with a high evening temperature in whom the physical signs were very similar to those of the last case mentioned, and two needles had already been inserted in the lower part of the chest without result. I put in a needle high up in the axilla and was surprised to find clear fluid, of which ten ounces were withdrawn. Microscopically, lymphocytes were present in abundance; the effusion was probably tuberculous.

A very rare position for an empyema is between the mediastinum and the lung. I have only seen one case:

CASE V.

An elderly gentleman had a very severe influenzal pneumonia of the left lung, during which he was desperately ill. He had a good deal of pleurisy over the left lower lobe. After a fall by lysis the temperature rose again, and the lower lobe of the lung, which had appeared to be clearing, became dull and silent, but no pus was found by exploration. After some days he suddenly coughed up a quantity of pus, and continued to do so, the temperature meanwhile remaining hectic, and the lung dull and silent. The patient was then seen by Sir William Osler, who found a strip of resonance about three inches broad just to the left of the vertebral column over the angles of the sixth, seventh, and eighth ribs. He pointed out that, as the patient was spitting up pus, there was probably a pyo-pneumothorax, and he had a needle put into the resonant area just external to the angle of the eighth rib. Pus was at once obtained. Later a piece of rib, just beyond the angle, was resected, and a large empyema opened, which extended forward to a depth of eight inches, but was bounded externally by the lung, which was completely adherent to the parietal pleura.

In this case the pressure of the pus had collapsed the adherent lung and rendered it absolutely dull and silent. To take a different complication:

CASE VI.

A man was admitted to hospital under me, having had a bad cough for ten days and having been in bed for four days. He looked very ill, and his temperature was 102° to 103° F. He had signs of bronchopneumonia of the right middle and lower lobes, tubular breathing being most marked between the middle of the scapula and its angle. The numerous crepitations were coarser than those of lobar pneumonia. He was very thin, and myxodema was obtainable in unusually striking degree.

Three days later he spat about an ounce of blood, and the day after his sputum became most offensive. A small patch of cavernous breathing could then be heard in the centre of the tubular area. There was no history of any possible foreign body having been inhaled. A radiograph taken by Captain Morton showed a round abscess cavity surrounded by inflammatory thickening at the level of the sixth rib.

My corresponding surgeon was anxious to attack this, but my small experience of operation for abscess of the lung was so unfavourable that I decided to treat it medically by inhalation of creosote, carbolic, and iodine from a Burney Yeo inhaler for several hours a day. The result was complete cure in about six weeks, cough ceasing, physical signs all clearing up, and the man putting on over a stone in weight.

Another interesting case was one admitted to St. Mary's Hospital when I was house-physician in 1894.

CASE VII.

A soldier who had been spitting blood for a fortnight and complained of pain in the right side was found to have impaired resonance below the angle of the right scapula. Breath sounds were good down to the angle, but diminished below with fine crepitations; vocal resonance was increased. The right front was normal. The haemoptysis increased and his sputum consisted of nummulated sticky masses of bright red blood. No tubercle bacilli could be found nor cancer cells. In six weeks he lost $1\frac{1}{2}$ st. in weight. Signs in the chest had greatly increased. On the right front dullness began at the fifth space in the nipple line, and ran to above this level in the axilla. Breath sounds were diminished below the second space and entirely absent over the dull area. The right back was dull from the middle of the scapula downwards, there was some friction in the upper part, silence below. The heart was not displaced to the left, the apex being within the nipple line. Exploration of the back several times yielded no fluid or pus. The temperature was irregularly raised from 99° to 102° , but not of a hectic character. As the heart was not displaced the case was considered one of malignant disease of the lung. In another month the right side of the chest was dull up to the third rib and the spine of the scapula.

Post mortem a large ragged abscess was found in the front part of the middle and lower lobes of the lung into which large bronchi opened. The abscess was in contact with the chest wall as far as the mid-axillary line. Behind that, over the whole back, inflamed lung was adherent to the chest wall, the lung being two or three inches in thickness, which accounted for the exploring needles failing to reach the pus. Further, an abscess of the right lobe of the liver was found which projected

through the diaphragm, and on examining the large intestine typical recently healed ulcers of dysentery were seen.

The course of events in this case had evidently been dysentery, tropical abscess of the liver, which burst through the diaphragm and led to abscess of the lung. The lesson to be learnt is that exploration should be tried in front of the chest when no fluid is found at the back. This was illustrated by a case under my care quite recently.

CASE VIII.

The patient was a soldier who had had a long illness with continued pyrexia and occasional attacks of diarrhoea. The stools had been found negative to typhoid, paratyphoid, and dysentery. There was dullness and silence over the lower half of the right chest, back and front. The liver was felt an inch below the costal margin, and appeared rather more enlarged towards the middle line, where it was also tender. I failed to get fluid by a needle inserted into the back of the chest, but in the anterior axillary line I drew off a pint of chocolate-coloured pus, typical of hepatic abscess. Colonel Jowers subsequently opened a large abscess in the upper part of the liver, and the man is doing well.

The next case was supposed to be an empyema of the right side of the chest, but needles had been put in in four different places without obtaining any pus before I saw him.

CASE IX.

The man looked very ill, and had been running a hectic temperature for a couple of weeks. The back of the right chest was dull up to three inches above the angle of the scapula.

Breath sounds were absent and vocal resonance was much diminished. In front of the right chest there was dullness from the fourth rib downwards external to the nipple line, but, between the nipple line and the sternum, instead of the usual liver dullness, there was an area of tympanitic resonance. On percussing over this with two coins a loud bell note could be heard with the stethoscope, and the same bell note could be heard as far as the left anterior axillary line, and down to the umbilical level. On rolling the man over on to his right side most of this tympanitic area to the right of the sternum was replaced by the absolute dullness of fluid. Obviously here was a gas-containing cavity, and the diagnosis was subphrenic abscess due to perforated duodenal ulcer. A needle passed deeply into the right sixth space in the tympanitic area immediately drew off foul-smelling pus. After operation the patient made a slow recovery.

By a singular coincidence, since the meeting was adjourned, a case has been sent into hospital under me as pneumonia, because there was tubular breathing and some fine crepitations over the lower half of the right back with a temperature of 102° .

CASE X.

On listening to the front of the right chest breath sounds were fairly normal down to the level of the nipple, below which they ceased abruptly. On percussion resonance was good down to the fourth rib, but hyper-resonant below over the liver area. On tapping one coin on another a bell note could be heard from the fourth rib down to the umbilical level in the mammary line.

The edge of the bell note area curved upwards to an inch above the umbilicus, and passed three inches to the left of the middle line, crossing the left costal cartilages, and then back across the sternum, about an inch below the level of the mamma. External to the right mamma the bell note area extended beyond the posterior axillary line round to the lower part of the back of the chest. The heart was pushed upwards and outwards, the apex beat being in the fourth space, two inches outside the nipple. It was impossible to feel anything in the abdomen itself as it was kept so rigid. The diagnosis was, of course, a right subphrenic abscess. A needle inserted in the eighth space in the anterior axillary line brought away foul gas and thin fetid pus. The same evening a portion of the tenth rib in the mid-axillary line was removed and a large amount of pus and gas let out. When this had been done an irregular hard mass could be felt in the right side of the abdomen, about the umbilical level, which might have led to further operation if the condition of the patient had not been so bad. Unfortunately the man died two days later.

At the *post-mortem* examination a perforation of the duodenum was found, $\frac{1}{2}$ in. in diameter, which had thick edges, as if of some weeks' standing. The abscess was limited below by

FIG. 1.

FIG. 2.

adhesions of the colon and edge of the liver to the abdominal wall with thick inflammatory tissue; this was the hard irregular mass felt at the operation. The falciform ligament formed the left limit.

A subphrenic gas-containing abscess under the left wing of the diaphragm is caused by perforation of a gastric or duodenal ulcer with a slow leak of the stomach contents, so slow that there is often no history pointing to ulcer. The abscess is limited below by adhesions of the great omentum and the front of the stomach to the abdominal wall, to the left by the spleen and gastro-splenic omentum. On the right it is bounded by the falciform ligament of the liver, which, as the abscess enlarges, is pushed very much to the right of its normal position, even to the right nipple line, as in the first case described. Abscess under the right wing of the diaphragm is much rarer, and is more usually due to inflammation of a retrocolic appendix causing an abscess communicating with the colon than to a perforated duodenal ulcer. Its boundaries are by adhesions of the edge of the liver, the transverse colon, and the omentum to the abdominal wall, the mesocolon, and the falciform ligament, which in this case is pushed well over to the left of the middle line. The gas evolved in these foul abscesses makes the area over them tympanitic, and the bell note is heard on the use of two coins.

The pressure upwards of the diaphragm and the inflammation invariably cause changes at the base of the lungs. With gastric ulcer it is the left lung which is affected; with duodenal ulcer sometimes the left and sometimes the right. At first a pleural friction is very often heard over the lower part of the lung, usually at the back, but sometimes in front as high as the fifth rib. In a case of perforated duodenal ulcer where there was no vomiting, this friction over the right lower front led to a few hours' hesitation as to whether it was only a case of diaphragmatic pleurisy, but commencing loss of liver dullness soon settled the diagnosis. The friction is usually followed by adhesion of the pleural surfaces and progressive collapse of the lung, or by a low form of pneumonia. In a few cases there is a clear pleural effusion, and instances have occurred where, a needle having been inserted and clear fluid withdrawn, an accidental push of the needle has sent it through the diaphragm, and the clear fluid has been followed by pus. For some reason it is very rare indeed for pus to form above the diaphragm in these cases. The usual condition is for the lower half of the back of the left chest to become quite dull and silent. The temperature is hectic and suggestive of empyema, and the left base is suspected. But, on examining the heart, instead of finding it displaced to the right, its apex beat will be found external to the left nipple and up in the fourth space, owing to the pushing up of the diaphragm, and there will be a large tympanitic area from the fourth rib downwards.

CHOLEDOCHO-ENTEROSTOMY FOR CONSTRICTION OF THE COMMON BILE DUCT FOLLOWING A PERFORATED DUODENAL ULCER.

By W. A. SNEATH, M.B., CH.B., M.R.C.S.,

LATE HOUSE-SURGEON AT THE DREADNOUGHT HOSPITAL, GREENWICH.

This case is of interest as a rare sequel of perforated duodenal ulcer.

A German, aged 54, was admitted to the Seamen's Hospital, Greenwich, under the care of Mr. E. Rock Carling, on December 14th, 1912. The history was that he had been operated upon in Bremen in June. He stated that bile drained from the wound for several weeks; the flow ceased towards the end of October, when he was discharged. When he started work an incisional hernia developed in the epigastrium, and it was for this he came to the hospital.

Condition on Admission.

He was emaciated and slightly jaundiced, his appetite was capricious, and he had a special distaste for protein and fatty foods. There was a healed scar in the right iliac fossa and a transverse scar running from the tip of the ninth costal cartilage across the right rectus muscle to about two inches beyond the linea alba; it was stretched, and near the costal margin was superficially ulcerated. When the patient strained a large ventral hernia, the size of a football, protruded through the cut recti muscles. The opening in the

latter measured 3½ in. from above downwards and 6 in. from side to side. At the right margin of the scar was a depression, apparently at the place where the abdominal cavity had been drained. There was some thickening and induration of the wound, and more deeply could be felt a vague resistant tender mass passing backwards into the right loin. The faeces were clay-coloured and contained no bile. The urine contained bile; no sugar was present.

The resistant mass on the right side increased, and the jaundice became more pronounced. The temperature rose to 100° F., and five days after admission a sinus formed at the side of the depression in the upper scar, and large quantities of bile escaped. The jaundice rapidly disappeared, but the faeces still contained no bile. After some days the sinus closed, but it opened again subsequently. Consequently, on January 2nd, 1913, Mr. Carling decided to operate.

First Operation.

An incision was made along the upper transverse scar. The omentum, which was adherent to the sac of the hernia, was dissected off and found to be tucked up over the front of the liver. After this had been separated the transverse colon, which was also adherent to the liver, was drawn down. At this stage some coils of small intestine adherent to the sac of the hernia had to be repaired after damage in detaching them.

The biliary sinus was then dissected out and traced downwards and backwards, where it entered a large cystic swelling situated deeply in the right loin on the outer side of the duodenum. This was opened, and 6 oz. of thick, viscid, green bile escaped. The wall of this swelling was lined by mucous membrane; on further investigation it proved to be a dilatation of the common bile duct; the gall bladder was fibrosed and contracted, and contained a small quantity of glairy mucus only. On dissecting out the cystic duct a small quantity of non-odorous, thick yellow pus was discovered between the first part of the duodenum and the liver. The pylorus was adherent to the neck of the gall bladder. There were other adhesions between the omentum, small intestines, and stomach, but these were too numerous to separate.

Diagrammatic schema showing the dilated common bile duct and the site of constriction of the duct. A, Site of obliteration of common bile duct; B, fibrosed gall bladder and obliterated cystic duct; C, choledocho-enterostomy; D, entero-enterostomy; E, transverse mesocolon.

The opening in the dilated common bile duct was brought forwards and sutured to the peritoneum at the right margin of the wound and a drainage tube inserted into the cyst. A tube was also sutured in the gall bladder, and cigarette drains were put above and below the cyst, on account of the escape of bile that occurred during the manipulations. The sac of the hernia, along with the adherent skin, was cut away, and the margins of the neck of the sac drawn together by strong silk mattress sutures. The skin wound was closed by silkworm-gut sutures. The operation was attended by a good deal of shock.

After-History.

The tube in the gall bladder was removed the next day as no bile was draining through it; the upper cigarette drain was removed on the second day and the lower drain on the fifth day. Bile drained through the tube in the dilated common bile duct freely (3x a day). The wound was kept dry by draining the bile away with a Sprengel's pump. The wound healed very well and the deep sutures held perfectly. After the operation the faeces continued to be clay-coloured, and the sinus showed no attempt to close.

On thinking over the problem which the case presented, it seemed clear from the many peritoneal adhesions present that there had been a general peritonitis, probably of perforative origin. The lower incision in the right

iliac fossa pointed to it being appendicular, but the history that the patient gave of bile draining from the upper wound for several months suggested that it either had something to do with the gall bladder or the second part of the duodenum. From the huge dilatation of the common bile duct it was concluded that there must be some blockage of the common bile duct, and this could only have arisen from an impacted gall stone or from a perforated duodenal ulcer. The most likely explanation of the condition was thought to be that there had been a perforated duodenal ulcer the cicatrix of which had constricted the common bile duct. The local inflammation around the gall bladder had at the same time involved and obliterated the cystic duct, so that the gall bladder had not yielded to the pressure of the secreted bile.

A letter from Dr. Sattler of Bremen subsequently confirmed these surmises. He stated that he operated upon the patient on June 12th, 1912, for a perforated duodenal ulcer with general peritonitis. The surroundings of the ulcer were very necrotic and there were many adhesions to the stomach and gall bladder; the peritoneal cavity was full of pus and bile, so that a counter-opening for drainage was made in the right iliac fossa.

Thus it was evident we were dealing with a case of constriction of the common bile duct following a perforated ulcer of the duodenum. As there was no bile entering the intestine it was decided to endeavour to construct a new channel for it by making an opening between the dilated common bile duct and the small intestine.

Second Operation.

On January 23rd, 1913, a vertical incision was made through the outer margin of the right rectus muscle. The sinus was dissected out and traced to the dilatation of the common bile duct. The latter had contracted down markedly since the previous operation. The sinus was cut away and the opening in the bile duct so made was clamped. The bile duct was freed and the clamp brought as far forward as possible, but owing to the density of the adhesions and the contraction of the bile duct since the previous operation very little relaxation could be obtained.

A loop of jejunum was then brought up through the transverse mesocolon and an anastomosis was made between this loop and the dilated bile duct by two rows of silk sutures. This was rendered difficult by the fixity and the depth of the "duct" and the friability of its walls. The sutures were unevenly placed and there was considerable tension on them. When completed the opening would admit two fingers. Owing to the fixity of the bile duct it was impossible to draw back the loop of jejunum through the aperture in the mesocolon; hence it was found necessary to perform a lateral anastomosis between the afferent-efferent portions of the loop on the under surface of the transverse mesocolon in order to prevent intestinal obstruction.

A cigarette drain was put in the region of the choledoch-enterostomy, and the abdominal wall was closed by through-and-through silkworm gut sutures.

The patient stood the operation extremely well, owing, no doubt, to his greatly improved general condition.

After-History.

Two days after the operation, on the removal of the cigarette drain, bile was noticed coming along the track, but as the faeces contained bile it was obvious that some bile was finding its way into the intestine.

The condition of the patient at this time gave rise to anxiety. He was vomiting freely, the temperature was 101° F., and the pulse 120. A drainage tube was again put in, and shortly afterwards, besides bile, the discharge contained digestive juices. The skin around the sinus rapidly became excoriated, but this was controlled by bismuth and paraffin. The patient became emaciated, the faeces were pale and fatty, and the appetite poor.

After six days the amount of bile and digestive juices escaping gradually diminished and the appetite rapidly improved. The stools became darker and he began to put on weight.

At the end of a fortnight the discharge ceased, the sinus rapidly closed, and the faeces became normal in colour and content.

On March 3rd, when the patient was discharged, he looked extremely well. The abdominal wall was quite strong save at the right margin of the transverse incision where the drainage tubes were at the first operation.

The size of the hernial opening and the difficulty of dealing with it suggest the inadvisability of transverse division of the recti in suppurative conditions which preclude adequate suture.

Although a sinus obviously formed at the site of the choledoch-enterostomy owing to the difficulty of adequately suturing the anastomosis, it healed rapidly and did not interfere with the efficiency of the new passage.

An account of constriction of the bile ducts following

the cicatricial contraction of a duodenal ulcer is given by Moynihan in *Duodenal Ulcer* (1910). He describes two conditions:

1. When the ulcer was situated near Vater's ampulla, and constricted both the common bile duct and the pancreatic ducts.

2. When the common bile duct alone may be involved as it runs behind the first and second parts of the duodenum.

Details of eleven cases of the first class are given, and of five cases of the second class, of which one was his own. No case is recorded in which the constriction followed a perforation of a duodenal ulcer. The cases recorded are all of the very chronic type of ulcer, in which there is marked induration around the base.

The case described here falls in the second group of cases, in which the common bile duct alone was involved. Since the ulcer perforated into the peritoneal cavity, and not into the retroperitoneal tissue, the ulcer must have been situated in the free part of the duodenum—that is, in the first or at the junction of the first and second parts.

The fact that bile was present in large quantities in the peritoneal cavity suggests that the ulcer had perforated through the bile duct in addition to the posterior wall of the duodenum. Whether the bile duct was caught in the sutures which were used to close the ulcer, or whether the constriction followed the cicatrization of the ulcer, is not clear. The fact, however, suggests that in these cases great care should be exercised in suturing the perforation lest the bile duct be involved.

In this case it was impossible to perform an anastomosis between the bile duct and the duodenum owing to the numerous adhesions around the latter. The comparative ease with which the anastomosis can be performed by bringing a loop of jejunum through the transverse mesocolon, and the perfectly satisfactory result ultimately obtained, points to choledoch-jejunostomy being the operation of preference in these cases.

My best thanks are due to Mr. E. Rock Carling for permission to publish this case, and also for the kind assistance he has given me in reporting it.

A CASE OF HAEMATIDROSIS.

BY

CHARLES T. SCOTT, M.B.CANTAB.,

MARKET HARBOROUGH.

THE following case was brought to my notice by Dr. H. Adcock, of Middleton, Northants, in conjunction with whom these notes are written.

Madeline —, aged 11 years, a bright intelligent girl of rather nervous temperament, commenced to have abnormal perspirations about four months ago, following a "chill on the liver"; since then they have been gradually growing more and more frequent and severe.

The sweats occur upon the forehead only, from the eyebrows to the roots of the hair, and as far as the outer margins of the orbits laterally; they consist of either clear watery fluid or white froth or bright pink fluid. At the present time they recur at intervals of from a minute to an hour, but during waking hours there is rarely a lapse of more than five to ten minutes, and often there are as many as eight "sweats" in ten minutes.

The "frothy" are the most common variety, accounting for 60 of a counted consecutive hundred; the red variety formed 34 per cent. and the watery 6 per cent. They are most frequent soon after waking in the morning and towards bedtime. The quantity secreted at each "sweat" is from 10 minims to 1 drachm; the secretion invariably appears rapidly, so that in a second the forehead is bathed in sweat, and occasionally it is so rapid that it can be seen as it issues from the forehead in a fine jet and can be heard upon the bedclothes. There is a distinct aura, which takes the form of a faint "sick feeling" in the epigastrium, more severe when a coloured sweat is heralded, so that the child will say, "A pink one is coming now," or "Now there is a frothy one," and her prognosis is invariably correct.

There are no sweats during sleep, but she is frequently awakened by one coming on; as a rule she sleeps for some hours at night with no sweats, but her rest is always disturbed by waking for sweats.

During the last few weeks the salivary glands have been affected in a similar manner to the sweat glands of the forehead, and the same aura may herald a sweat or a "mouthful," which latter may also be pink or white.

For the last fortnight she has had attacks of tonic spasm of the muscles of the arms, so that the hands may become rigid in the "accoucheur's position," or she may involuntarily grasp some object, or the hands may be raised and tightly pressed against the back of the head, causing pain in the back and sides, suggesting hysteria. She has suffered from almost continuous headache, frontal and occipital, since the sweating began. She has had no vomiting.

From a scraping of the skin of the forehead staphylococci and streptococci were grown in small numbers only. Histological examination of the sweat shows red and white blood corpuscles in all three types of sweat, but far more in the "pink" sweat than in the others. Bacteriological examination shows staphylococci, a few streptococci, and a Gram-negative bacillus, apparently of the Friedländer group.

The patient was a premature child (eight months); her mother was badly frightened shortly before the birth by being stabbed in the head by a burglar. She has always been addicted to walking and talking in her sleep, but has had no serious illness. A few years ago tenotomy was performed upon both eyes for strabismus. She has not shown any signs of menstruation. There is no tendency to haemophilia in the patient or her family.

Just a week before the sweats commenced she had a very severe shock. Being particularly nervous of air raids, her parents tried to keep her out of their way; one day a gas explosion occurred in the next house while the child was in bed; she was frightened by the noise.

Examination reveals no abnormal signs in the nervous system, heart, lungs, or digestive system. The urine is copious, up to 6 pints daily, is acid, sp. gr. 1020, and contains no albumin or sugar. The reflexes are very brisk and the fundi healthy.

The case would appear to be one of an unusual type of functional disturbance consequent upon the shock of the explosion. It has not hitherto proved amenable to treatment.

INTERMITTENT HAEMATEMESIS FOLLOWING ON AN INJURY TO THE CHEST.

BY

CAPTAIN A. H. D. SMITH, M.B., CH.B. EDIN., M.C.,
ROYAL ARMY MEDICAL CORPS.

THE interesting point about the following case is that there were no symptoms of any sort until the patient was injured in 1915. The haemorrhages have all taken place after excessive exertion. Apart from the discomfort and fright caused by the haemorrhages he is in no way handicapped by the condition.

History.

Private K., aged 39, consulted me on March 4th, 1918, on account of haematemesis. In October, 1915, when a cavalryman, he was kicked in the precordial region by a horse. He attended hospital for eight weeks as an out-patient. As far as he knows the ribs were not broken, but he was in strapping for the whole eight weeks. He was said to be suffering from a severe contusion of the chest; there was no vomiting or spitting of blood after the injury, and beyond pain there were no symptoms of any sort; previous to the injury he was quite well, and had been training for service overseas since June, 1915.

Before enlistment he was in extensive business as a book-maker. Both his parents are alive and well; there is no history of heart disease, lung disease, or apoplexy in the family. He has three children alive and well; his wife is healthy, and there have been no miscarriages.

The patient's history is as follows: He has always enjoyed excellent health; there is no specific history. For many years he was a heavy spirit drinker, on occasions drinking as much as one and a half bottles of whisky a day, and he averaged three-quarters of a bottle of whisky daily for ten years. Some three years ago he consulted a medical man, who told him he had a diseased condition of the liver, and advised him to give up spirit drinking; since then he has been for all practical purposes a total abstainer.

Since the injury he has suffered from intermittent precordial pain; about every six months he has had attacks of haematemesis. The attacks come on suddenly without warning, usually during violent exertion. About half a teacupful of blood comes away with a gush; there is no pain at the time

but for a short time after the vomiting he has difficulty in breathing. In the intervals between the attacks he is quite well, but since the accident he has suffered from insomnia.

On February 27th, 1918, while walking up a slope against a very strong wind, he found difficulty in breathing, and blood suddenly rushed into his mouth. Again, on March 3rd, while walking sharply uphill, the same thing happened, only in this case the blood was clotted. He was short of breath for some time after the attack, but was able to walk four miles home and carry on his work next day.

Physical Examination.

Respiratory system: Nothing abnormal found; no evidence of old fracture of ribs.

Circulatory system: Nothing abnormal; no thickening of vessels; no varicose veins.

Nervous system: No objective symptoms.

Abdomen: Much tenderness on palpation over liver; this organ (by percussion) decreased in size; spleen also tender, but not as tender as liver; no history of jaundice; nothing abnormal found otherwise.

Genito-urinary system: No abnormal condition discovered; urine normal.

Haematopoietic system: Nothing abnormal.

Facilities for a more elaborate examination were absent at the time.

Differential Diagnosis.

The haematemesis has, of course, to be differentiated from haemoptysis. In this case there is no history of cough, or of pulmonary or heart disease. Apart from the injury in 1915 there is no reference to any chest trouble. The patient states that the blood is in his mouth before he has any warning, and that on March 3rd the blood was clotted.

The patient can give no information as to the presence of food in the vomit. There is no history of melaena. The absence of pain in the intervals helps to differentiate from gastric, duodenal, and oesophageal ulcers (peptic). The absence of wasting helps to differentiate from malignant disease. The absence of anaemia is a strong point in excluding ulceration of any sort.

There is no haemophilia or abnormal blood condition; there is no affection of throat or nose which might account for the haemorrhage. The history of excessive spirit drinking spread over many years (confirmed by condition of liver and spleen found on examination) points to the condition being secondary to the hepatic (or splenic) condition.

Treatment.

The patient has been advised to abstain from spirit drinking and lead a normal, active, healthy life, but to avoid all undue exertions, such as rushing upstairs and walking quickly up hills. He has been advised to take his meals slowly and not bolt his food, and to abstain from drinking very warm fluids. No drug treatment has been given.

I think the probable cause of the recurrent haemorrhages is a varicose condition of the veins at the lower end of the oesophagus. The absence of any arterio-sclerosis excludes a small aneurysm. The veins may have been injured by the trauma to the chest, and so an extra strain has been thrown on veins already weakened by cirrhosis of the liver and spleen.

I beg to acknowledge the kindness of Surgeon-General Julian, D.D.M.S. Western Command, for permission to publish this case.

THE PHAGOCYTIC RESPONSE TO THE INTRODUCTION OF BACTERIA INTO CLEAN WOUNDS.

By W. JAMES WILSON, M.D., D.Sc.,

BREVET MAJOR R.A.M.C.(T.F.).

(From the Laboratory of — General Hospital, B.E.F., France.)

IN the course of an extensive experience of the bacterial flora of war wounds I have been struck by the small numbers of *B. coli* which are present as the wound tends to clean. Even wounds of the buttock which are repeatedly contaminated with faeces contain after a few days comparatively few *B. coli* although they are swarming with enterococci.

At first I imagined that the explanation of the selective effect of the wound on faecal flora might be that the wound fluids offered an unsuitable medium for the growth of *B. coli*. No doubt this is an important factor, but the following few experiments show that the immunity is an active one, and that the phagocyte plays an effective part in its production.

Experiment I.—Fate of Living Culture of *B. coli* Introduced into a Clean Wound.

The patient (R.) had a wound (6 cm. by 5 cm.) of right forearm just below the elbow-joint. On November 23rd, 1917, the wound was granulating, and a swab taken on that date gave a growth

of enterococci but no *B. coli*. On November 22nd a culture of *B. coli* had been made from patient's faeces, and on November 23rd 1 c.cm. of a very thick emulsion of the growth was introduced into a small depression of the wound, and films were made at intervals so as to study the effects.

After five minutes a few leucocytes and many *B. coli* were seen. After sixty minutes numerous leucocytes were present, and many of the bacilli were intracellular. After two hours the fluid in the wound had become thicker, stringy, and contained plenty of leucocytes. It was, in fact, becoming purulent. After six hours the majority of the bacilli were intracellular. After twenty-four hours no bacilli could be seen on direct examination of films, but in culture numerous discrete colonies were obtained. After forty-eight hours the wound, which was now quite clean again, showed leucocytes and connective tissue cells in film, but no micro-organisms were visible. On culture *B. coli* was absent, but enterococci were still present.

Experiment II.—Effects of Brilliant Green on Phagocytosis of *B. coli* in a Clean Wound.

On November 27th, 1917, in the same wound as used in Experiment I, 0.5 c.cm. of a thick suspension of *B. coli* was added, and immediately followed by an equal volume of 1 in 1,000 brilliant green solution.

Films made after five minutes showed leucocytes and numerous *B. coli*; after fifteen minutes more leucocytes and some phagocytosis; after two hours there were still leucocytes and some phagocytes, and after six hours a fair number of pus cells; no bacilli visible. On culture a few *B. coli* colonies developed as well as the persistent enterococci. On November 28th cultures yielded no *B. coli*.

Experiment III.

There was a little saucer-shaped wound (3 cm. in diameter) in the front of the chest, just over the right pectoral muscle. The bottom of the wound involved the muscle fibres. On November 26th, 1917, this wound appeared very clean and no bacteria could be seen on films made from it. The addition of distilled water to the little wound cavity led to the emigration of leucocytes into the cavity, and a loopful planted out yielded four colonies of a long chained streptococcus; 0.5 c.cm. of a thick suspension of *B. coli*, derived from a culture from the patient's intestine, was added to the wound on November 27th and immediately followed by 0.5 c.cm. of 1 in 1,000 brilliant green solution.

Films made after five minutes showed many *B. coli* and no leucocytes; after fifteen minutes many *B. coli* and a few leucocytes; after two hours some phagocytosis of the *B. coli*. At this stage the edges of the wound were stained green and its cavity contained a clear watery fluid. At the end of six hours the wound cavity was full of yellowish pus; no bacilli could be seen on films made at this stage. Cultures made from the pus yielded a considerable number of discrete colonies of *B. coli* on an agar slope. At the end of twenty-four hours a few *B. coli* were seen in films and cultures were still positive. At the end of forty-eight hours the film showed very few leucocytes, and some of these contained bacilli; the cells present were mainly of the mononuclear connective tissue type. On culture a loopful of wound secretion yielded 100 discrete colonies of *B. coli* on an agar slope.

A culture made after seventy-two hours yielded twenty discrete colonies. On November 30th, a swab was taken from the wound (this yielded about twenty colonies of *B. coli*), and then the wound was moistened with an emulsion killed by heating to 70° C. There was a free exudation of leucocytes, and films showed, at the end of one hour, phagocytosis and bacteriolysis of the cocci; at the end of seven hours no cocci could be seen in the cells or outside them; they had been completely destroyed.

A culture made on agar at this stage yielded no growth. In Experiment III the wound was covered over with a watchglass, and the pus in it remained in its saucer-shaped cavity, and was not lost by adhering to dressings. There was no question, therefore, of the mechanical removal of the bacilli and cocci. The wound was left covered with the watchglass until December 2nd, and when examined then (that is, forty-eight hours after the vaccine was put in) yielded only two colonies of *B. coli* when an ose was planted out.

Experiment IV.

A gunshot wound of shoulder which was healing offered a suitable little pocket for holding emulsion of bacteria. A swab taken on December 5th, 1917, yielded twenty colonies of streptococci on an agar slope; 0.33 c.cm. of a very thick emulsion of dead staphylococci was introduced into the wound on December 7th. A film made immediately afterwards showed no pus cells but enormous numbers of well-stained cocci. At the end of one hour the great majority of the staphylococci were inside the leucocytes, many of the latter being crammed with them. The staphylococci stained badly, and were evidently being digested. After six hours the majority of the cocci had disappeared, but an occasional leucocyte could be found filled with them. At the end of twenty-four hours little pus was present and no trace of staphylococci except a few intracellular cocci. A culture on agar at this stage yielded seven colonies of streptococci.

Experiment V.

From a wound of the right wrist a foreign body had been removed on December 7th and a clean gutter-shaped wound was left. On December 10th a film showed very few cells and no bacteria. On December 11th a thick emulsion of *B. welchii*

was introduced; this was really a vaccine, as the culture contained no spores and had been heated to 70° C. After one hour there was a fair degree of emigration of leucocytes and pronounced phagocytosis; after six hours there was no trace of bacilli.

In a patient with I.C.T. of the right leg the introduction of a thick emulsion of dead staphylococci led to a zone of redness round the ulcer.

CONCLUSIONS.

1. Experiments *in vivo* demonstrate the rapidity with which leucocytes migrate out and destroy micro-organisms introduced into a healing wound.

2. Experiment II indicates that brilliant green momentarily arrests this protective action, but later on, when the dye has been absorbed by the skin, etc., the process goes on. Whether the rapid bactericidal effect of chemical substances on free bacteria compensates for their inhibitory action on the leucocytes is open to doubt.

3. Circular wounds a few centimetres in diameter can in a few hours destroy thousands of millions of *B. coli*.

4. Vaccines introduced into a wound lead to a prompt leucocytic reaction, and this fact might be of service in the treatment of sluggish sores and ulcers.

5. These few *in vivo* experiments would convince the most sceptical of the truth of Metchnikoff's theory of phagocytosis, and confirm what has been long ago demonstrated *in vitro* by Leishman and Wright.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PERFORATING WOUND OF THE HEART: DEATH ON THE FIFTH DAY.

PERFORATING wounds of the heart are sufficiently rare in civil life to justify a record of the following case.

A boy 16 years of age was stabbed with a large pocket knife on April 1st by another boy aged 12, after leaving a cinema performance. Helped by a friend, the injured boy walked about six yards, then collapsed and fell down.

He was conveyed to the local hospital, where I saw him a few minutes after admission. He was very pale, collapsed, and pulseless. There was a vertical incised wound in the third intercostal space immediately to the left of the sternum; there was fairly free venous haemorrhage. Cardiac dullness was completely absent, and the heart sounds were muffled. Pulmonary resonance and the breath sounds were normal, as was the temperature. The wound was cleaned and lightly plugged with cyanide gauze. Half a pint of warm water was given by the rectum.

The next day the patient was comfortable with a temperature of 98° F. The pulse was 112 and irregular; the respirations 17. Cardiac dullness, though less than normal, could be made out. No pericardial friction was heard. On April 3rd the temperature was 101.8° F.; he was flushed, and complained of some pain in the region of the wound. There was no pericardial friction; the heart sounds were still muffled. Pulmonary resonance and breath sounds were normal. On April 4th the temperature came down to 99.4° F. There was less pain, and the patient was altogether more comfortable. Cardiac dullness slightly more than normal; no friction.

On April 5th the temperature rose to 101.8° F.; breathing was short and shallow, and a small patch of pleurisy could be made out at the base of the left lung. Pulmonary resonance was normal, the pulse 110, and the respirations 20.

On April 6th the patient died quite suddenly after drinking a little warm milk.

Post-mortem Examination.—A quarter of an inch to the left of the sternum in the third intercostal space was a clean vertical incised wound half an inch long dividing the cartilage of the fourth rib. There was a vertical wound of the pericardium corresponding to the skin wound. The pericardium was distended with blood-stained serum, and contained one large clot. Pericarditis was marked. An incised wound of the anterior wall of the right ventricle penetrated to the cavity, and a small abrasion and some ecchymosis was found on the septum between the two ventricles. Otherwise the heart was quite healthy. There was a small patch of pleurisy at the base of the left lung,

which was slightly congested. The anterior edge of the right lung was slightly collapsed; otherwise the organ was healthy.

Hæmorrhage in this case was slight considering the extent of the injury. The fact that the wound was vertical, in the direction of the fibres of the heart, may account for this; had the wound been transverse, hæmorrhage would have been much more free, and the patient would probably have died at once. It is difficult to account for the disappearance of the cardiac dullness. The absence of the physical signs of the pericarditis is noteworthy.

C. F. WIGHTMAN, F.R.C.S. Eng.,
Surgeon, Royston Cottage Hospital.

LOSS OF HEAD IN AEROPLANE ACCIDENTS.

IN the crashes that occurred during the nine months that I have been attached to the Royal Flying Corps it has seemed to me that loss of head was by far the most common cause. I had thought of loss of head in rather a wider sense than Mr. Graeme Anderson,¹ and meant it to include any condition in which the pilot is incapable of acting synchronously. Of course, when a pilot is shot or faints in the air, he can hardly be said to have lost his head; still the effect is the same, in that he ceases to act synchronously. The following seem to me the most usual predisposing causes of loss of head:

1. *Lack of Confidence.*—This explains itself.
2. *Lack of Mental Training.*—I mean the training that enables one to grasp a situation and act immediately (almost reflexly) for the best. Driving a car through traffic or sailing on a crowded river would give such training.
3. *Congenital Tendency.*—Some people are more prone to lose their heads in an emergency than others. These men, who are noticeable on an unexpected night raid or on a torpedoed ship, would require extra training as pilots.
4. *Mental Fatigue.*—This is a very real fatigue during the first hours of flying. Personally, after attempting to send wireless messages on my third or fourth solo flight, I slept for most of the rest of the day, and I am sure that Mr. Graeme Anderson's view of this condition is the right one.
5. *The Influence of Ill-advised Conversation.*—It has often been remarked that crashes occur in epidemics, especially when a new type of machine is issued to a school or when someone has crashed in sight of a number of pupils; there follows a great deal of argument in the pupils' ante-room as to what should or should not have been done, and opinions are expressed many of which are quite erroneous. This results, I think, in pupils losing their heads from a multiplicity of advice.
6. *Insufficient Instruction.*—This is, happily, rare, and is becoming rarer, though it occasionally occurs, especially when pilots are urgently required for some special reason. It must be remembered that the instructor's job is not easy. He has to teach his pupil to fly, and gauge his nervous capacity, confidence, and judgement; to do this he must allow him complete control at all heights, and at the same time be ready at the fraction of a second's notice to take over control in the case of an error in flying or of threatened collision with an early soloist in another machine. Since most instructors in this country are in the air with pupils for about three hours a day, and are encouraged to turn out the largest possible number of soloists per month, I think it is extraordinary that crashes caused by too little instruction are as rare as they are.
7. *Fear (Pure Funk).*—To become mentally paralysed by fear alone is, I believe, very rare. The sense of self-preservation is strong, and seems to me to be stimulated by fear. Personally, on my second solo flight, I lost control and was so frightened that I nearly vomited, but was able to regain control in time to land without damage.

What is wanted, I think, is some quick method of picking out the very worst of the pupils. I am informed that it costs over £2,000 to train a pilot, and those who fail frequently crash at least one machine, value, say, £1,500. If only 2 or 3 per cent. could be eliminated, thousands a year could be saved, more time could be spent on successful pilots, and lives valuable in other spheres could be spared to the country.

J. EATON LASCELLES,
Captain R.A.M.C. (T.), attached Royal Air Force.

A CASE OF SYPHILITIC REINFECTION.

ON March 29th, 1917, a patient was seen by one of us, in conjunction with Mr. Frank Kidd, for a small ulcer on the penis, which he had noticed for four days, coitus having taken place six days and six weeks previous to the appearance of the sore.

The *Spirochaeta pallida* was found in large numbers in the sore; the Wassermann reaction was negative, and in view of this the probability was that the infection took place from the coitus ten days previously. Three intravenous injections of galyol, 0.4 gram, were given, the last on April 15th, 1917. No mercurial treatment was given. The sore healed rapidly and there were no further manifestations of syphilis.

The patient was not seen again till July, 1917, when he was advised to have a Wassermann reaction done. He, however, did not follow the advice, and it was not till February 3rd, 1918, that he again came, as he said he feared he had a recrudescence of the old infection.

On examination there was a small group of herpetic vesicles the size of a threepenny piece on the lower lip, and he had nasal catarrh. The Wassermann reaction was taken and was negative. The patient did not come again till February 16th, when he complained of "swelling of the neck." Examination now showed an erosion of the lower lip covered with a yellowish-grey false membrane with distinct induration around the base and edges. The submaxillary lymphatic glands on the right side were very enlarged and hard, bulging out under the lower jaw (the giant bubo). The *S. pallida* was found in the erosion and the Wassermann reaction was completely negative. The patient gave a history of having kissed a girl about three weeks previously.

The diagnosis of extragenital chancre was made, and the same day an injection of 0.6 gram novarsenobillon was given, followed by three more, each of 0.9 gram, given at weekly intervals; twenty-four hours after the first injection the swelling of the glands had entirely disappeared, and ten days later the sore had completely healed.

This seems an undoubted case of reinfection in syphilis, the following conditions being satisfied. In the first infection in March, 1917, a sore developed on the penis, the *S. pallida* being found in large numbers, and the Wassermann reaction being negative. In the second infection eleven months later, in February, 1918, a sore developed on a different site—on this occasion being on the lip—the *S. pallida* being found in the sore and the Wassermann reaction being negative, thus excluding a diagnosis of chancre redux, chancreiform gumma, or indurated secondary lesion of the lip.

Surgeon, Out-patients, St. Paul's Hospital.

THE EFFECT OF ULTRA-VIOLET RAYS ON THE SKIN AND EYES.

IT was with great interest that I read the article by Dr. Oscar Holden of Southampton, in the BRITISH MEDICAL JOURNAL of April 20th, p. 454, on the effects of electric arc welding upon the eyes and skin. I should like to know what electrodes were used in this process and the length of time to which the operators were exposed to the light.

For the last two years I have been treating patients, both in military hospitals and in private, with ultra-violet rays. The light is produced from wolfram electrodes, and latterly by pure metal electrodes, and I should like to know what electrodes Dr. Holden used (p. 454). The exposure for wounds varies from one and a half to three minutes—that is, until a definite reaction occurs. For other conditions the time may be slightly increased.

The reddening of the skin, though slight at the end of the treatment, is very much more marked within two or three hours, and particularly so if the patient washes the part treated. An exposure of the back for two minutes at a distance of a foot can cause desquamation at the end of three days. This is not due to the heat produced, as there is only a moderate degree of rise of temperature even when the ray is allowed to impinge directly on or is focussed on the bulb of a thermometer. I have exposed many x-ray plates enclosed in light-proof envelopes. Lead seems to be a slight protection. Whether the rays are conducted or

¹ BRITISH MEDICAL JOURNAL, January 19th, 1918, p. 73.

transmitted by glass I know not, though they can certainly be deflected by quartz. An x-ray plate covered by a sheet of $\frac{1}{8}$ -inch lead, with a hole the size of half a crown in the centre, was uniformly fogged, nor was there any shadow of a metal disc placed directly in the centre of the aperture. I have learnt of lacrymation and conjunctivitis by bitter experience when giving several treatments during a day. I have not yet been able to discover any adequate protective glasses. Lead blue, green, and Crookes's yellow, do not seem to absolutely cut out this particular ray. In spite of the fact that one's eyes are protected by a metal screen placed behind the arc, the ray seems capable of being reflected from the walls of the room in which the treatment is given. Pigmentation of the skin is in some cases very marked.

Reports of Societies.

CHOICE OF OPERATION FOR MYOMA OF THE UTERUS.

At a meeting of the Section of Gynaecology and Obstetrics of the Royal Society of Medicine held on May 2nd, Dr. G. F. BLACKER, the President, being in the chair, Dr. HERBERT R. SPENCER gave an account of two cases of myoma of the uterus treated by total abdominal hysterectomy, in which cancer of the body was present.

Case I was an instance of recurrent cancer in which the growth involved the peritoneum. The recurrent mass was removed, together with the lower end of the right ureter, and the right half of the bladder. The kidney became infected subsequently and was removed. There was a second recurrence, which was inoperable. Death occurred twenty-six months after hysterectomy. In Case II the growth (in an unmarried woman aged 49) had advanced to within 1 mm. of the peritoneum. The patient was well and free from recurrence after five years.

Dr. Spencer declared himself an advocate of total abdominal hysterectomy for myoma. He had never amputated a uterus for cancer of the body, whether complicated with myoma or not. Three experienced gynaecologists, advocates of amputation for myoma, had overlooked cancer of the body as a complication and performed amputation (or, in one case, incision before removal) in 14 out of 18 cases (77 per cent.), and in no case was a five-year after-history given. Two of these three gynaecologists had overlooked cancer of the body uncomplicated with myoma, and performed amputation in 3 out of 12 cases (25 per cent.), 2 of the 3 cases recurring (66 per cent.). Advocates of amputation for myoma needed to take greater care than advocates of total hysterectomy in making the diagnosis of cancer of the body as a complication, and should clamp the uterus before dividing (with the cauter). Total abdominal hysterectomy by Doyen's method, the vagina being opened and severed with the galvano-cautery, was superior to amputation for myoma, in that it lessened the risk from cancer of the body, should it have been overlooked.

In the course of the discussion, the PRESIDENT said that he had seen only one case of cancer of the stump after the supravaginal operation. Most operators considered that they did not get such a good result from total hysterectomy as from this operation, which was both safer and simpler. The number of cases of cancer of the stump was so few that the danger to the patient from the more severe operation of total hysterectomy was greater than the possible chance of the occurrence of cancer. Mr. J. D. MALCOLM said that he always removed the uterus completely except in cases of simple fibroid. Dr. H. RUSSELL ANDREWS thought that cancer of the body would not be overlooked if histories were taken very carefully. A distinct interval of amenorrhoea—eight months to a year—occurring when periods had been profuse, was very suggestive of a new condition. Dr. R. A. GIBBONS thought it important to leave the pelvic floor. Mr. OSWALD DINNICK said that if total hysterectomy were well done convalescence was easy and smooth, more so than in the case of the supravaginal operation. There was no rise of temperature and less danger of sepsis. Dr. LAPHORN SMITH said that he always did total hysterectomy in suspicious cases.

ANNUAL CONGRESS OF THE OPHTHALMOLOGICAL SOCIETY.

The annual congress of this society was held at the Royal Society of Medicine, London, last week. On the first day the president, Mr. Treacher Collins, read a paper on an experimental investigation as to some of the effects of hypotony in rabbits' eyes. The immediate changes on tapping the eye were found to vary according to the site of the incision. If the anterior chamber were opened, then fluids were found to pass from the anterior surface of the iris; if the posterior chamber were opened, fluids passed into the vitreous from the posterior surface of the ciliary body and from the retina. Colonel Elliot made a contribution to the histology of the trephined disc; Mr. George Thompson spoke on herpes zoster affecting the ciliary nerves; Captain Cruise read a further note on the use of the visor; Mr. Freeland Fergus contributed a paper on vision and work, founded on the results obtained at a recruiting office; Mr. George Young suggested clinical tests for the threshold of light and colour; Captain W. Wallace discussed the dioptric mean in the myopic soldier; Colonel G. McPherson gave a note on the use of glare glasses; and Captain Thomson Henderson spoke on contracted sockets. In the afternoon there was a discussion on plastic operations of the eyelids, opened by Major H. D. Gillies, Messrs. C. Higgins and Harrison Butler, and continued by Major A. W. Ormond, Captain R. Cruise, Mr. M. S. Mayou, and Captain F. Derwent Wood. Of much interest was a method of deepening a shallow lower fornix of the conjunctival socket described by Major Gillies. An epithelial graft was removed from the leg or other suitable place and wrapped round a wax mould of the intended extension of the socket. The conjunctiva was then incised, and the incision extended until the graft-wrapped wax could be buried and sutured beneath the conjunctiva. The graft became an implantation cyst. When time had elapsed for the fixation of the graft the conjunctiva was incised over the cyst, the wax removed, and the pocket formed kept open by suitable shells. The report of the special committee on the conditions affecting the standards of vision in the British army was received. On the second day a visit was made to the Metropolitan Asylums Board Ophthalmia School at Swanley, where a discussion took place on contagious diseases of the conjunctiva. In the evening a clinical meeting was held in London, at which a large number of cases were exhibited, and some novelties in instruments for investigating fields of vision demonstrated. The morning of the third day was devoted to a visit to the National Hospital for Paralysis, Queen Square, where a number of cases were shown by Dr. Kinrier Wilson, Dr. James Taylor and Mr. Leslie Paton, and discussed.

PROPHYLAXIS IN VENEREAL DISEASE.

At a meeting of the London Association of Medical Women on April 9th, with Lady BARRETT in the chair, Dr. MORNA RAWLINS, in a paper on prophylaxis in venereal disease, distinguished between prophylaxis in general and personal prophylaxis. For general prophylaxis, education of the medical profession, of nurses, and of the lay public was of great importance. Systematic lectures were now given to the general adult population, and especially to the army. Infected persons were instructed at the various clinics. Prostitution was a breeding place of venereal disease, but the Contagious Diseases Acts should be strongly opposed as they gave false security to men. Moreover, the diseases were conveyed more by amateur than by professional prostitutes, and these were not touched by the Acts. To fight prostitution every one must have a living wage. Personal prophylaxis before coitus was known as prophylaxis proper, and after coitus as early preventive treatment. Men were given outfits containing argyrol, or a similar medicament, and calomel, etc., but this treatment was full of fallacies. For women nothing was done. The American navy employed early preventive treatment; after illicit intercourse a rigid course of treatment was enforced. The percentage of venereal disease was very small in consequence, as was also the number of men having illicit intercourse, the enforced treatment probably acting as a deterrent. The time at which treatment was carried out was important; if within eight hours success was practically certain, and disease was usually prevented

even after forty-eight hours. Preventive centres would probably soon be set up all over the country. The speaker asked, in conclusion, whether it was possible or desirable to set up early preventive treatment centres for women also.

Reviews.

THE PARASITIC THEORY OF TUMOURS.

ALTHOUGH the proper function of hypothesis is to furnish a basis for research amongst investigators, nevertheless the etiology of tumours is a subject of such exceptional interest that the publication of Dr. D'ESTE EMERY'S small work entitled *Tumours, their Nature and Causation*,¹ will doubtless prove acceptable to many general readers.

The author has brought together in a succinct manner the different problems in connexion with the biology of new formations as they now present themselves. He himself is impressed with the theory that now growths have a parasitic origin—a somewhat old proposition; for it was formally set out by Ballance and Shattock in 1887 (*Path. Soc. Trans.*, vol. 38). By a parasitic hypothesis is meant, of course, the action of an extraneous virus. The cells of a malignant growth have themselves been regarded as parasitic (by the late Sir Henry Butlin) in the sense that they invade and produce a fatal metastasis in the host. But no advance is made by applying such a terminology to what is actually witnessed, unless some explanation of the altered biological character of the cells is forthcoming.

Dr. Emery would extend the parasitic doctrine to cover not only malignant but benign tumours. Many of the holders of the doctrine, however, will not follow him in this. The great character of a malignant tumour, even though it may be quite minute, is its power of local invasion and dissemination; that of a benign tumour, however large, is the absence of such a property. To many this fundamental difference will indicate a different kind of pathogenesis. Cohnheim's original theory of cell-rests will still appeal to many as satisfactory in regard to some of the forms of innocent tumours, though it has its limits. No adequate explanation can at present be offered, to take an example, for the growth of a simple circumscribed lipoma. The experimental grafting of tumours in the lower animals, the prophylactic immunization of animals, and kindred subjects, are briefly dealt with by Dr. Emery, so that altogether an excellent view may be gained by the general reader, of the present position of knowledge and theory in regard to the subject of neoplasia.

LIPINS.

THE substances extracted from organs and tissues by ether and alcohol may be roughly classified as neutral fats and fatty acids, substances having no relation to fats, such as cholesterol and some pigments, and the fat-like bodies dealt with in the volume under the title of *Lecithin and Allied Substances*, by Dr. HUGH MACLEAN.² The word "lipoids" has been used vaguely, and has not been restricted to the fat-like phosphatides and cerebro-sides, and as for this reason it is not applicable, the word "lipins," which is also unfortunately not entirely free from confusing associations, is employed by the author for these bodies. They are defined as substances of a fat-like nature, yielding on hydrolysis fatty acids or their derivatives, and containing in their molecule either nitrogen or phosphorus. Of the phosphatides, which Leathes, who wrote the volume on fats in this series, suggested would more conveniently be called phospholipins, lecithin and the closely related cephalin are the best known, while of the cerebro-sides, which do not contain phosphorus, there are only two—phrenosin and kersin.

Dr. Maclean gives a very thorough account of lecithin and of the allied and other bodies reputed to belong to this group, and in doing so has handled a difficult and rather dry subject most efficiently, and in places with

flashes of welcome humour. Protagon, described in 1865 by Liebreich and the cause of bitter discussion since, is considered at length, and the author concludes that it is a mixture of cerebro-sides and sphingomyelin with traces of other bodies. Similarly, jecorin, carnaubon, and other bodies alleged to be definite lipins, are also adjudged from the available evidence to be mixtures. Throughout the monograph, which is of a high standard and fully worthy of this biochemical series, full due is paid to Thudichum's brilliant but now neglected work, and it is shown that recent work is in many instances only confirmatory of his experimental results. Much research has given barren results in connexion with this subject, and there is little positive knowledge as to the function of lipins. The belief that lecithin can act as an antigen in the Wassermann reaction is disproved by the author's and Dudgeon's experiments, which show that this depends on the presence of an unknown substance, difficult to separate from lecithin, and similarly its curative effect on beri-beri disappears as it is more highly purified.

THE USES OF TUBERCULIN.

IN a paper addressed to the Ulster Medical Society in November last, and now published in book form,³ Dr. J. R. GILLESPIE, Tuberculosis Medical Officer for county Down, discussed the various methods of using tuberculin, and placed on record his own experiences at the five dispensaries under his control. The actual number of cases treated was not very large, but the percentage of success would appear to have been markedly higher among the dispensary cases treated with tuberculin in the manner recommended than among sanatorium cases and others treated at their own homes. Believing that the conflicting results observed and recorded by other users of tuberculin are essentially due to want of uniformity of method in administration, Dr. Gillespie pleads for a more strictly graduated system both of dosage and of interval between doses, the greatest caution being observed to avoid excessive reaction. With this principle in view, however, it is still absolutely necessary to deal with each case individually, and no hard and fast lines can be laid down for general guidance. A tabulated statement of the cases dealt with during the years 1913-15 inclusive is appended.

NOTES ON BOOKS.

IN *The Happy Hospital*,⁴ Mr. WARD MUIR gives a sympathetic account of the life of a military hospital from the orderly's point of view, under such titles as "Problems of a Ward Orderly," "The Orderlies' Recreation Room," "Night Convoys," and so on. If he has any disposition to criticize organization he represses it, although he ventures the suggestion that the employment of male nursing orderlies in military hospitals—he means, no doubt, base hospitals—will some day cease, and tells an amusing story of the reform of the men's mess after a visit from the assistant matron. The work of Mr. (now Captain) Derwent Wood, A.R.A., in the department of masks for facial disfigurement, is described, and a well-deserved compliment is paid to him, and also to the officer in command who helped him to discover what he could do. The most moving chapter in the book is "Transport," and very good it is. From the same publisher comes an Australian detective story, *Many Thanks*—Ben Hassett, purporting to be written by HERBERT DE HAMEL, which contains more cases of mistaken identity to the page than any we remember.

We welcome the appearance of the eighth edition of Professor STELWAGON'S treatise on *Diseases of the Skin*,⁵ a well written and scientific manual that has long been valued in this country as well as in America. It is full of practical hints, well up to date, and admirably illustrated. Many references to the literature are contained in its pages; the book may be warmly commended to the general practitioner of medicine as well as to the specialist. The third edition of Professor PUSEY'S

¹ *Tumours, their Nature and Causation*. By W. d'Este Emery, M.D., B.Sc. London: H. K. Lewis and Co. 1918. (Crown 8vo, pp. xx + 146. 5s. net.)

² *Lecithin and Allied Substances: The Lipins*. By Hugh Maclean, M.D., D.Sc. Monographs on Biochemistry, edited by R. H. A. Plimmer, D.Sc., and F. G. Hopkins, M.A., M.B., D.Sc., F.R.S. London: Longmans, Green, and Co. 1918. (Med. 8vo, pp. vii + 206. 7s. 6d. net.)

³ *A Rational Method of Using Tuberculin in the Treatment of Pulmonary Tuberculosis*. By John R. Gillespie, M.A., M.D., D.P.H. Belfast: Graham and Heslop. 1918. (Med. 8vo, pp. 33. 2s. 6d. net.)

⁴ Simpkin, Marshall, and Co., Ltd. 1s. 6d.

⁵ *A Treatise on Diseases of the Skin*. By Henry W. Stelwagon, M.D., Ph.D., Professor of Dermatology in the Jefferson Medical College, etc. Eighth edition, revised. Philadelphia and London: W. B. Saunders Co. 1916. (Roy. 8vo, pp. 1309; 356 figures, 33 full-page coloured and half-tone plates. 28s. net.)

*Principles and Practice of Dermatology*⁶ offers the reader a sound general discussion of the subject, and is well illustrated. It affords a considerable contrast in style and outlook to the more ambitious volume on *Diseases of the Skin*⁷ by Professor HARTZELL, in which the attempt has been made to cater for medical readers of all classes, informed and uninformed alike. Here much space is given to etiology and pathology, and treatment is naturally considered less fully. The illustrations are excellent, and include no less than fifty-one coloured plates.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.

THE thirty-fifth annual general meeting of the Medical Sickness, Annuity, and Life Assurance Friendly Society was held on May 3rd, when Dr. F. J. ALLAN presided.

The CHAIRMAN in his address reported that, as in the case of every insurance company, the amount of business done during the year showed a falling off. The society had to deplore the loss of seventeen members who had died from wounds or illness contracted at the front, while two lost their lives in a hospital ship which was torpedoed. The claims for sickness benefit of members on active service amounted to £3,575, which was slightly in excess of 1916. The sum paid as sickness disbursements in respect of 618 civilian claims during the year was £14,357; this included twenty-nine members who were on the funds for the whole year, some of whom had been permanently incapacitated for several years. The total amount of sickness experienced during the year, however, was 22 per cent. below the expectation, and the amount paid out in 1917 was £2,223 less than in the previous year. The sum of £3,676 had been paid in annuities, which showed an increase over 1916, and the increase was one which would normally continue for some years, as no business had been done for many years under the old tables under which the annuities had been taken out. The Life Insurance Fund was gradually growing, and the new tables introduced appeared to be much appreciated. There had been an increase in the Management Fund, due partly to the cost of paying a proportion of the salaries of the members of the staff who had joined the forces and the expense of engaging substitutes to do the work, partly to the great increase in the cost of printing, stationery, lighting and heating, and partly to the decision of the committee to pay a fee of £1 ls. to the practitioner who examined a candidate for insurance. In view of the depreciation of all securities since the last valuation of the society's assets, it had been thought advisable to ask Mr. Warner, President of the Institute of Actuaries, to make an examination of the society's financial affairs at the end of 1917 rather than at the end of the present year. The result showed that the society was in a thoroughly sound financial position. Arising out of the report was a suggestion to transfer £4,884 from the Sickness Fund, which amounted to £176,105, to the Annuity Fund, in order to bring the required reserve of the latter up to the proper standard. The Reserve Fund of £20,000 was considered by the auditor to be sufficient to meet the depreciation at the end of 1917 on all stocks. In view of further likely depreciation owing to the war, the committee, on Mr. Warner's suggestion, considered it safer to recommend the suspension of the payment of any bonus in connexion with the Sickness Fund. The committee proposed, however, to allot a reversionary bonus of 25 per cent. on the whole life assurances in the Life Assurance Fund.

On the motion by Dr. W. K. SIBLEY for the adoption of the report, Dr. BEATON expressed the opinion that to stop the bonus would be a hardship on the members who would shortly be going out of benefit on reaching the age limit, and moved to refer back the paragraph of the report referring to this matter. The amendment was seconded by Dr. VINRABE, but, on being put to the meeting, was lost, and the original motion that the report be adopted carried.

⁶ *The Principles and Practice of Dermatology*. By William Allen Pusey, A.M., M.D., Professor of Dermatology in the University of Illinois. New York and London: D. Appleton and Co. 1917. (Med. 8vo, pp. xxiv + 1243; 54 plates, 466 figures. 30s. net.)

⁷ *Diseases of the Skin: Their Pathology and Treatment*. By Milton B. Hartzell, A.M., M.D., L.R.C.P., Professor of Dermatology in the University of Pennsylvania, Philadelphia and London: J. B. Lippincott Co. 1917. (Med. 8vo, pp. xiv + 753; 242 figures, 15 coloured plates. 30s. net.)

Certain alterations in the rules, which the CHAIRMAN explained were proposed with a view to making clear certain points, were adopted.

The list of officers nominated were elected, Captain the Hon. Rupert Guinness, C.B., C.M.G., M.P., being appointed a trustee in the vacancy caused by the death of Sir Victor Horsley.

The CHAIRMAN then gave informally particulars of the report of a subcommittee which advised the conversion of the society into a company under the Assurance Companies Act, 1909, in order to enable it to undertake insurances for larger amounts; at present its scope was limited under the Friendly Societies Act. Dr. DE HAVILLAND HALL said that the whole trend of insurance work was in favour of amalgamation instead of forming new companies. Dr. SIBLEY said the committee had received several propositions to combine with insurance companies; and while it saw that it would be greatly to the benefit of the companies to combine with the society, it had failed to see any benefit which would accrue to the society. The CHAIRMAN announced that of approximately 1,100 who had replied to his circular letter to members on this subject, 970 were in favour of the scheme, 112 were against the proposal, and 25 were neutral.

SPECIAL SCALES OF RATIONS FOR HOSPITALS, ETC.

THE Ministry of Food has issued (May 6th, 1918) to the local food offices particulars of special scales of rations for hospitals, sanatoriums, and kindred institutions. These scales have been drawn up by the Food Controller after consultation with the medical officers of the Ministry of Food and of the Local Government Board, with the Medical Committee of the Food (War) Committee of the Royal Society, and with an Advisory Committee of Hospital Managers.

The scale for civil general hospitals is as follows, the quantities being the average per head per week, as purchased, for all classes of patients taken together:

Meat*	16 oz.	Potatoes	70 oz.
Poultry or game or fish† ...	32 "	Fresh vegetables ...	23 "
Sardines and other dried	Milk	8 ½ pts.
or preserved fish	4 "	Jam	8 oz.
Bacon (boneless)‡	4 "	Rice§	8 "
Bread	70 "	Oatmeal and pulses§ ...	4 "
Sugar	8 "	Eggs	4 "
Butter and margarine	4 "	Cheese 	4 oz.

* The term meat denotes meat of all kinds, and the whole or any part of the allowance may be taken out in the form of butcher's meat.

† As from May 5th and until further notice, a ration of 8 oz. of bacon per head per week may, at the option of the hospital, be substituted for the whole of the ration of 32 oz. of poultry or game or fish per head per week.

‡ Or the equivalent current amount purchasable on one coupon, whichever is the larger.

§ In Scotland the scale will read, rice, oatmeal, and pulses 12 oz.

|| Cheese should be used as little as possible, and only the less solid kinds.

The civil general hospitals scale is applicable to general hospitals, to most special hospitals, to Poor Law infirmaries, and to the sick wards of other establishments classed as institutions under the meat rationing scheme; and also, under certain conditions, to convalescent homes and nursing homes. It will apply not only to in-patients, but also to the medical, surgical, and nursing staffs.

Special scales have also been drawn up for children's hospitals and for tuberculosis sanatoriums (including special tuberculosis wards of other institutions), whilst naval and military patients treated by understanding with the naval or military authorities are entitled to the naval and military hospital patient's scale. The medical, surgical, and nursing staffs of these institutions will receive the civil general hospitals scale, except that at sanatoriums they will, if themselves tuberculous, receive the same scale as the patients.

Applications to be registered as entitled to a special institutional scale must be made to the local food office. The same hospital may apply for more than one scale. There may, for instance, be naval and military patients, civilian patients and professional staff, and tuberculous patients in special wards, besides other residents and non-residents receiving ordinary rations as members of the general public.

INVALID RATIONS.

The order as to special rations for invalids (M.G.R.M. 27), discussed by Dr. Spriggs in a paper published last week, will shortly be supplemented by the issue of an abbreviated leaflet (M.G.R.M. 27a), which will be supplied by the Ministry to food offices for circulation to registered medical practitioners in their districts.

OWING to the dangers of using rat and mouse viruses the German authorities have recently issued instructions to prevent careless use and to limit the risks.

British Medical Journal.

SATURDAY, MAY 11TH, 1918.

MEDICINE IN PARLIAMENT.

THE new reform act which became law on February 6th will not take effect until Parliament is dissolved, but the large task of making the new list of persons entitled to vote has been begun. It is probably safe to assume that there will be no general election until the new register is ready. It was thought at first that it might be completed by October, but the President of the Local Government Board stated the other day that it could not, and he did not give any clear indication of when he thought it would be ready. At the same time the present House of Commons is old, if not senile, and there can be little doubt that no long period will elapse after the register is completed before we have a general election. Already the constituencies are looking out for candidates, and the grinding of the old party machinery can be heard. Consequently it is full time that the medical profession should consider what means it can take to ensure an adequate representation of medicine in Parliament.

It is therefore very opportune that the Council of the British Medical Association, at its meeting a fortnight ago, should have determined to take steps to raise a voluntary fund from members of the Association to assist the candidature of such members of the medical profession as may be adopted as candidates for parliamentary seats. The suggestion seems to us more practical than some of those which have been put forward in the past. It recognizes that the medical profession cannot in any one constituency ensure by its own votes the election of a member, and the resolution goes on to affirm that the assistance contemplated should be given to medical candidates of any party whose membership of the House of Commons appears to the executive body of the fund to promote the interests of the medical profession. Many details will have to be worked out, and the Medico-Political Committee of the Association has been instructed by the Council to set its Parliamentary Subcommittee to consider the methods for carrying out the principle contained in the resolution.

The air is already full of schemes for reconstruction, and the Ministry of that name is engaged, with the aid of numerous committees, in examining many of them and in evolving some of its own. Many of the reconstructive policies which have been announced or foreshadowed touch nearly the future of public health, medicine, and the medical profession. For this reason it is more than ever necessary that the medical profession should take all steps in its power to ensure that it shall be adequately represented. The Annual Representative Meeting in 1914 resolved "that the representation of the medical profession in Parliament at the present time is inadequate, and in the interests of the public and the profession alike should be improved." In 1909 the opinion had been expressed that the medical profession should be represented in the House of Lords as part of the legislature. And this principle would apply to any second chamber which may result from the proposals for the reform of the House of Lords.

In addition to what may be done in ordinary constituencies along the lines indicated above, the medical profession may reasonably hope to have a considerable influence in the selection of university representatives in Parliament, and it might perhaps best achieve its object by working in harmony with other professions and callings interested in science. The number of members the universities are entitled to elect has been increased by the new Act from nine to fifteen. One representative is given to the University of Wales; two to the universities of Durham, Manchester, Liverpool, Leeds, Sheffield, Birmingham, and Bristol, voting as one constituency; an extra member to the four Scottish universities, which will in future, voting as one constituency, have three representatives; and two new members to the Irish Universities, one elected by graduates of the National University and the other by the Queen's University of Belfast. The university franchise is open to men and women graduates on the same terms, with the exception that a woman must have attained the age of 30 years. The university franchise is in addition to, and not in substitution of, the ordinary right to be on the register and to vote for the locality in which the person resides or has his place of business; that is to say, a person may vote on his residence qualification, and also in his university constituency. Under the new Act a man is entitled to be registered on his residential qualification in one constituency, and on his business qualification in another constituency, but if he makes use of his university qualification he foregoes the right of claiming the business qualification. He may exercise only two votes—one in respect of residence qualification, and one in respect of any other qualification—namely, business or university. The definition of "business" is held to include such qualification as is afforded by the tenure of a surgery or consulting rooms in a constituency other than that of residence.

A register of graduates entitled to vote will be kept by the university authorities; the persons entitled to vote are, generally, those who have received a degree other than an honorary degree from the university, but a woman has the right to be on the register if she has passed the final examination and kept, under the conditions required of women by the university, the period of residence necessary for a man to obtain a degree, though the university did not admit women to degrees at the time she passed the examination. The governing body of each university is required to cause a register to be kept of persons entitled to vote, but it is eminently desirable that every graduate should take care to ascertain from the authorities of his or her university that the name is on the university register. This is essential in the case of graduates of the old Queen's University in Ireland and of its successor, the old Royal University of Ireland, since they have an option between the Queen's University of Belfast and the new National University, Dublin, as is more fully explained elsewhere in this issue. The elector will vote at a poll by the delivery of a signed voting paper in a certain form, though in England, Ireland, and Wales a provision may be made for voting in person. The returning officer will be, as a rule, the vice-chancellor of the university. Nomination must take place not less than four days and not more than twelve days after the receipt of the writ, and the poll must be opened not less than three clear days after the day of nomination and not more than twelve; it will remain open for five days. Some of these details are of importance to medical graduates who may be serving abroad. As will be seen, the longest possible

time between the issue of the writ and the close of the poll is twenty-nine days, and the longest possible time between the nomination and the close of the poll, which is the period of practical importance, is seventeen days. This outside interval of seventeen days, which may, if the returning officer so directs, be reduced to eight, will be by no means too long, and makes it all the more important that all medical graduates should at once communicate with the authorities of their university.

A contested election for a university constituency having more than two members will be conducted according to the principle of proportional representation, each elector having one transferable vote, which is defined as "a vote capable of being given so as to indicate the voter's preference for the candidates in order and capable of being transferred to the next choice when the vote is not required to give a prior choice the necessary quota of votes, or when, owing to the deficiency in the number of votes given for a prior choice, that choice is eliminated from the list of candidates." The governing body of a university may direct that a person who before the passing of the Act had received a degree, but was not entitled to vote in respect thereof, shall have no right to be registered unless he makes a claim for the purpose.

ACIDOSIS AND DEATH.

ACIDOSIS has recently attracted much attention, especially in America, where Joslin, once an ardent advocate of the alkaline treatment of diabetic acidosis, now believes that its dangers outweigh its advantages; Howland and his collaborators at the Johns Hopkins Hospital have done much good work on the acidosis of renal disease and of food poisoning in children; and Sellard's monograph containing an account of the acidosis of renal disease and of cholera was reviewed in this JOURNAL on January 5th last. In the same number Dr. B. A. Peters brought forward evidence to show that some of the symptoms in the grave vomiting cases of diphtheria may be due to adrenal exhaustion caused, according to Crile, by a previous acidosis. This observation fits in with Whitney's conclusion that infection has a very well-marked influence in causing acidosis, for Peters's cases received antitoxic serum somewhat late in the disease.

Some recent studies on acidosis, which we also owe to Whitney,¹ contain an interesting discussion of the part played by this condition in causing death, and thus open up a wide field for inquiry. Why does an organism which has carried a load of disabilities for perhaps many years break down altogether at one particular time rather than at another? On the answer to this and other questions rational treatment must depend. Of the ways in which death comes the most common is paralysis of the respiratory centre, and this in its turn is in the majority of instances due to soluble poisons; toxic proteoses, for example in intestinal obstruction, may be responsible, and so may acids. The effect of an increase of acid radicals is first to stimulate and then to paralyse the respiratory centre, and it makes little difference whether this finally increased acidity is due to carbon dioxide or to other acids. Shock has interesting relations with the subject of acidosis and death; the phenomena of shock are to all intents and purposes the same as those of the terminal states preceding death, and Martin Fischer and Yandell Henderson believe that acidosis of the tissues accounts for the passage of the fluid parts of the blood out of the vessels, which is an important feature of shock.

Out of a number of human cases investigated by Whitney the great majority showed a more or less well-marked acidosis at the time of death, and in many of these the acidosis was so considerable that it alone could have led to respiratory paralysis, and so may be assumed to have been the cause of death. But death itself, or the state preceding it, does not necessarily cause acidosis; for in two cases of pyloric stenosis with gastric tetany there was the opposite condition of alkalosis, and two cases of circulatory failure without acidosis are quoted. Infection appears to be a powerful factor in causing acidosis; thus all the cases of acidosis except one showed evidence of severe infection, and the cases without acidosis were not infected. But there may be well-marked infection without acidosis provided the urinary excretion is properly maintained. Thus in pneumonia among the young and previously healthy persons there may be an absence of acidosis and a low mortality, whereas it is a deadly disease for the aged and for patients with chronic disease, especially nephritis. The terminal acidosis due to infection develops rapidly, and is usually followed by death in a few days or even a few hours; this suggests that the influences restraining acidosis are in most conditions extremely efficient, and also that their failure is followed by rapid and fatal accumulation of acid products.

In his brief remarks on the treatment of acidosis Whitney points out that alkalis should not be given indiscriminately, for the neutralization of the acid ions is not the only thing to be considered; the salts thus formed must be eliminated, and if excretion is so poor as to allow acidosis to develop it is probable that these salts will also accumulate, and possibly to a highly dangerous concentration in the blood and tissues. Diuresis should therefore be promoted by giving large quantities of fluid by the mouth, under the skin, or perhaps best by J. B. Murphy's drip method of continuous rectal injection. Fresh air should be provided in the form of a gentle breeze across the face to prevent the rebreathing of carbon dioxide, which may prove the last straw to the overloaded respiratory centre. Morphine, which is well known to be a respiratory depressant, must also be used with great caution.

CINQ ANS APRES.

IN 1912 the inexorable age limit of 65 deprived the Massachusetts General Hospital of the services of Dr. F. C. Shattuck, but with the entry of his country into the war he returned to his post, or as he puts it was resurrected, and his attractive address¹ to the Johns Hopkins Hospital Medical Society contains some shrewd *obiter dicta* on what five years can do for hospital practice, which are interesting in the light of our experience on this side of the water. One striking feature is the fall in the number of typhoid patients, to 5 per cent. of the medical beds, as compared with its incidence in the past. Gastric ulcer, formerly common in women, now appears to be more frequent in men, and x-ray examination, as is the case in this country, has come to occupy a more important position, partly from improved methods but mainly from accumulated knowledge, while the surgical treatment has apparently become more discriminating than it was. Five years ago the fresh cold air treatment of pneumonia was in full swing at the Massachusetts General Hospital, and was perhaps more thoroughly carried out than at present. The strains of pneumococci had not been differentiated in 1912, and until the specific treatment is more fully developed the mortality must be expected to remain much the same; a review of this question shows that the mortality

¹ J. L. Whitney: *Arch. Int. Med.*, Chicago, 1917, xx, 931-950.

¹ *Bull. Johns Hopkins Hosp.*, Baltimore, 1913, xxix, 77-80.

has been practically unchanged during the varying phases of the old heroic bleeding and mercurial methods, of the expectant and alcoholic, of the symptomatic, and of the fresh air treatment. Dr. Shattuck suggests that the pendulum may have swung too far away from alcohol in grave cases, and asks if fifty years hence alcohol will be regarded as always, everywhere, and in all circumstances the unmitigated poison that it is to some present-day apostles and the American Medical Association; its undoubted abuse in the past does not affect the belief that in some instances it is life-saving, but, as Opie said of his pigments, it must be mixed with brains, and the best results are obtained only under skilled supervision which contraindicates the repetition of the dose while its toxic effects, such as flushing, or its odour in the breath, persist. The increased value of skiagraphy in the detection of gall stones of late years depends on the shortening of the time of exposure from twenty seconds to a fraction of a second. From a more general survey of the changes it appears that the increasing elaboration of reports and records is not free from the danger of obscuring the wood by reason of the trees, and it is well to emphasize the necessity of a brief, clear and consecutive summary of the essentials of a case—a moral which many writers of clinical articles might take to heart. With the multiplicity of instruments of precision the possibilities of investigation are becoming progressively so numerous that some patients now have time to die or get well before a really scientific diagnosis is reached, and there is a greater chance than formerly for the patient to be forgotten in the pursuit of his disease. Finally, the plea entered for humanism is most appropriate on the scene where a great humanist—now the Regius Professor at Oxford—scored so many of his triumphs.

PHYSIOLOGICAL ASPECTS OF FLYING.

THE physical qualifications for admission to the air service are necessarily high, but even now there is no finality about the standards, which are always subject to modification in the light of the experience accumulated from day to day. The medical assessors of the physical and nervous capacity of the flying man have had to formulate their testing methods gradually from a study of the airmen who have "made good." Previous observations of life at high altitudes were of little value for this purpose, because the airman, unlike the mountaineer, does not become acclimatized to the higher levels; the amount of time which a constant flier spends at a height above 10,000 ft. is extremely brief, even in a period of service measured by years. The only possible expedient, as Major Martin Flack, R.A.M.C., stated in his lecture at University College on May 6th, is to take as a criterion the physiological standards of the men who have withstood the sudden and violent accommodations which flying involves; certain definite conclusions as to the flying temperament also can be reached in the same way. The first physiological change on making a flight is an increase in the depth of respiration, although this is not immediately noticeable by the subject unless he watches for it; at a height of 12,000 or 15,000 ft., however, every man becomes a month breather. Next there occurs a quickening of the pulse, and then certain subjective and objective sensations, including possibly a certain amount of illusion, as a result of oxygen want. In some cases there is nausea and dizziness, and, exceptionally, fainting. Major Flack, in the course of his lecture, gave illustrations of the tests used in examining candidates for the air service. Among the first requirements, given general bodily soundness, is a large respiratory capacity. Any one with a respiratory capacity below 3,400 c.cm. should be regarded as a doubtful subject whatever his general physique. A firm and hard abdominal wall is also necessary. The response of the heart to a

definite amount of work has to be tested, during which the quickening is noted, and also the length of time taken to return to the normal. The diastolic as well as the systolic pressure are taken into account; when the former sinks below a certain level, even though the systolic is maintained, the man is considered unfit to fly. Other requirements are a high degree of visual acuity, keenness of hearing and ability to resist the tendency to deafness which sometimes accompanies the act of rising in the air, a capacity for maintaining bodily balance, delicate hands, and, generally, a sporting and fearless temperament. But standards can only be set up for other recruits by observing the men who have already worn well in actual service.

THE DEAF SOLDIER.

DR. DUNDAS GRANT contributes an interesting paper on the treatment and training of the deaf soldier to the third number of *Recalled to Life*, a journal devoted to the interests of disabled sailors and soldiers, the earlier numbers of which have already been noticed in these columns. The author, from his position as chairman of the special aural board appointed by the Ministry of Pensions, is in close touch with all the work that is being done on behalf of deafened ex-service men. The chief aim is to restore to these men the capacity for understanding and communicating with their fellows. Of the various ways and means, lip-reading is by far the most important. "When skill in lip-reading is attained," says Dr. Grant, "the individual is again made a sociable being, and is saved, to a great extent, from that isolation and self-inclusion which render him both sullen and suspicious." He next tells of his tour among French schools for the instruction and re-education of the deaf soldier. At one place he asked the chief gardener, an expert lip-reader, whether he could tell that he was not French, and received the answer that "les mouvements de vos lèvres ne sont pas les mêmes que les nôtres," showing that it is possible to see the foreign accent of a good linguist. Good results have already followed skilful teaching in France, and parallel work in the United Kingdom has recently been started, notably in Edinburgh. It appears that the number of soldiers so completely deafened by warfare as to be unfit for reasonable enjoyment of social and industrial life is relatively not very considerable, and that from three to six months' methodical instruction in lip-reading will usually remove their main disability to a notable extent. Although the number of the totally deaf is relatively not very great, there are many other discharged men with diseases of the ear and minor degrees of deafness for whom suitable treatment should be freely available in the form of aural out-patient clinics in convenient and accessible centres. Dr. Grant gives a very clear account of the functions of the special aural board. A point upon which he dwells more than once is the concentration of attention needed for the acquisition of lip-reading, leading to fatigue, especially in men who have worked hard at other pursuits during the day, and this is an obstacle to regular attendance at evening classes. For the purposes of the pensions department the United Kingdom is divided into areas, each under the control of a representative of the Ministry and one or more aural surgeons, with a lip-reading specialist attached. The chief difficulty so far seems to have been to get the men to respond to the invitations to come up for examination and training. This is, no doubt, due to the fact that during the present exceptional demand for labour even very deaf men are offered employment at abnormally high rates of pay. Hence the warning that when the war is over and healthy hearing men return to the labour market, the unfortunate victims of deafness who have not learnt to lip-read will find themselves elbowed out of their employment by the mere force of circumstances. Another factor in the small response is the mistaken idea that

a man's pension will be cut down when he has learnt to lip-read. The machinery for training now exists, and it is of the utmost importance for the men to profit by it without delay.

STATE PURCHASE OF THE LIQUOR TRADE.

THE reports of the three Liquor Trade Finance Committees were issued last week. It was necessary to appoint separate committees for Scotland, for Ireland and for England and Wales because the organization and legal conditions of the trade differ in all three countries. In Scotland, for instance, the Temperance Act of 1913 provides for local option at June 1st, 1920, which affects the estimate of goodwill, rights of compensation, etc. The reference to the committees confined them strictly to the financial questions relating to the terms upon which intervention in the manufacture and supply of intoxicating liquors should be acquired, and the financial arrangements during the period of control. The committees were not instructed to advise as to the need of control or the policy of purchase, the Government being of opinion "that it may shortly be necessary as an urgent war measure to assume control of the manufacture and supply of intoxicating liquors during the war and the period of demobilization, and that such control would involve the purchase after the war of the interests concerned in such manufacture and supply." The committees have kept closely to their reference, and their reports are in substantial agreement on all main points. The three committees agree that the Government cannot take control without an obligation to purchase, and that the purchase consideration should be arrived at by capitalizing pre-war profits, giving the holders an equivalent investment in Government stock. They agree that the scheme of purchase should include breweries with or without tied or managed houses, free houses, the interests of on-licensed tenants and of retail off-licences, but not hotels, restaurants, clubs, railway refreshment rooms and cars, steamer licences, and theatre and music-hall licences, allied trades, or the interests of wholesale dealers. Business carried on in shades or vaults of an hotel or restaurant would be included, as also the business of an hotel or restaurant which forms part of a brewery asset or is inseparable from the attached retail off-licence. The committee for England and Wales deferred a decision as to distillers and rectifiers until the Scottish and Irish committees had reported. These committees recommend the inclusion of such businesses in the purchase scheme. The Irish committee advises the reduction of licences in that country by at least one-half, with compensation to those suppressed from money raised entirely or largely by a special levy on the Irish trade. The purchase price suggested is fifteen times the annual profit ascertained for the five years before the war. The Irish scheme recommends twelve years' purchase on the net pre-war profit in the case of distillers. The committees recommend that persons losing employment, including holders of on-licences, should be compensated in accordance with a schedule. The total estimated cost is somewhat more than four hundred millions, but substantially less than five hundred millions.

A COUNCIL OF BRITISH OPHTHALMOLOGISTS.

A MEETING of ophthalmic surgeons and physicians was held at the rooms of the Royal Society of Medicine on May 2nd for the purpose of forming a council to take action in ophthalmological matters arising in connexion with public affairs. Mr. Treacher Collins, President of the Ophthalmological Society of the United Kingdom, was in the chair, and the resolution affirming that such a council should be formed was proposed by Sir Anderson Critchett. It would, he said, meet a definite need and tend to weld the elements of ophthalmology more closely together, as well as making for the welfare of the public. Mr. Richardson Cross (Bristol) seconded the

resolution, remarking that governments and governing bodies needed expert advice in order to be efficient, and the best experts were those who enjoyed the confidence of their colleagues in that special line of practice. Owing to the amalgamation of the journals devoted to ophthalmology, and the representation on the Ophthalmological Society of the various similar bodies in the kingdom, the profession was now well organized and could present a powerful front on all questions specially concerning it. He instanced ophthalmia neonatorum, army and navy visual standards, visual and lighting requirements in various kinds of industry, organized inquiries concerning the blind, and grades of compensation payable according to degrees of visual disability. Mr. J. B. Lawford, in supporting the resolution, said that the days were rapidly passing when the nation could afford to ignore scientific discoveries and the new methods based upon them. He believed more attention would be paid in the future to the views of representative bodies and less to the opinions of individuals, however eminent. We were much behind other civilized countries in that ophthalmology was not a compulsory subject of the medical curriculum. At present a man receiving the minimum qualifying medical diploma could at once take up the practice of ophthalmology; if the proposed committee did no more than insist that men should not take up this work without special training, it would fully justify its formation. Other speeches in support of the resolution were made by Mr. Grey Clegg (Manchester), Sir George Berry and Dr. G. Mackay (Edinburgh), and it was carried unanimously. It was further decided that the council should consist of all the past and present presidents of the Ophthalmological Society of the United Kingdom and of the Section of Ophthalmology of the Royal Society of Medicine as permanent members, four members nominated annually by the councils of each of these societies, and one representative from the Oxford Ophthalmological Congress.

SHAKESPEARE'S HANDWRITING.

DR. R. W. LEFTWICH put forward, at the fifty-ninth annual Shakespeare festival of the Urban Club on May 7th, a suggestion with regard to Shakespeare's handwriting which is ingenious and certainly fits well with some of the facts. The specimens which have been preserved of Shakespeare's handwriting all date from the later years of his life, from 1612 to 1616. They all appear so laboured that they must have been written very slowly. The difficulty is to reconcile the theory that he wrote slowly with his very large output. The inference from the statement of Hemming and Condell is that his penmanship of the plays was excellent, "his mind and hand went together," and the "William" of the full signature to the will proves that he was able to write at least a word or two well. If his later writing is so much worse than his earlier, the change must have been due to disease; yet it could not have been a constitutional disease, for, in the preamble to his will, Shakespeare solemnly declares that he is in perfect health. Now, all possible diseases, with one exception, are ruled out by age, duration, good mental capacity, the non-rhythmic tremor, etc. Dr. Leftwich's contention is that only one condition fulfils all the indications, and that is writer's cramp. To test this, he collected the opinions, as to the causes and the signs of the disorder, given by twelve eminent authorities on the subject. In the first place, as is well recognized, all persons who suffer from writer's cramp have been voluminous writers; that Shakespeare must have been a voluminous writer is proved by the fact that the first folio alone contains one thousand double columns. Again, a cramped position of the hand in writing is held to be one of the causes, and the handwriting of Shakespeare's time was cramped. The age also agrees: Shakespeare was 48 in 1612, and of 194 cases seen by Jelliffe 45 were in persons between the ages of 40 and 50.

With the help of facsimiles of the signatures the presence of all the signs enumerated by authorities was demonstrated by Dr. Leftwich, who concludes that the advent of the disorder in or about 1611—the year in which the last play, *The Tempest*, was produced—explains why Shakespeare retired to Stratford in the prime of life. The suggestion recalls the note in which Popps explained the reason why he gave up keeping his diary; in his case it was defective vision, probably due to failure of accommodation.

MEDICAL PRACTITIONERS UNDER THE MILITARY SERVICE ACT.

REGULATIONS giving effect to the provisions of the Military Service Act, 1918, rendering liable to military service medical practitioners who have not attained the age of 56 years, have been drafted by the Local Government Board, in consultation with the Ministry of National Service, and have been under the consideration of the Central Professional Committees. These regulations will probably be issued next week, and will come into force at once, since they are made under Section 1 of the Act. Medical practitioners brought within the scope of the Military Service Acts will receive at an early date a notification from the Ministry of National Service requesting them to appear for medical examination, as their cases are brought under review by the medical tribunals (the Central Professional Committees) in consultation with the Ministry. The places at which the medical examinations shall be made will be selected with due regard to the convenience of medical practitioners in the various areas as these are brought under review.

We understand that the bacteriological investigations have not so far confirmed the suggestion that the cases recently observed in London, Sheffield, and some other parts of the country, presenting obscure nervous symptoms characterized especially by ophthalmoplegia, are to be attributed to infection by *B. botulinus*. The diagnosis of botulism is therefore in doubt, and that of poliomyelitis cannot be excluded. The investigations into the nature of the disease are being made by the Local Government Board with the assistance of the Medical Research Committee.

Medical Notes in Parliament.

Criminal Law Amendment Bills.

In the House of Lords, on May 7th, second reading was given, on the motion of Viscount Sandhurst, to a Government measure, the Criminal Law Amendment Bill, which, subject to a few important alterations, has been modelled on the lines of a bill that passed through Standing Committee of the House of Commons last year, but could not be taken further. The Lords also gave second reading to a Sexual Offences Bill, introduced by Lord Beauchamp, and referred both measures to a Joint Committee of the two Houses.

In explaining the provisions of the Government bill, Lord Sandhurst said that Clause I would abolish the plea of defence that a person under sixteen consented to the act complained of. Clause II would withdraw as a defence the reasonable cause of belief that the girl was sixteen years old, and it proposed to extend the period during which proceedings might be taken to twelve months after the alleged offence. Clause III would enact that where any girl was convicted before any court that, "being a common prostitute," she loitered or importuned for the purposes of prostitution and solicitation, such a girl, under 18, might, until the age of 19, be detained in a home in lieu of punishment. The clause, he said, laid down that such a course should be taken only after most careful inquiry by a probation officer, or by a committee of which two of the members should be women.

The bill of last year did not restrict the application of the clause to "common prostitutes"; nor was a term for detention in a home given, as in this bill, with limitation of a year. As in the previous bill, there is right of appeal to Quarter Sessions against an order for such detention.

In regard to Clauses V and VI, dealing with venereal disease, Lord Sandhurst said that the position was much changed since the bill was originally drafted and introduced last year. Much was being done under the Venereal Diseases Act—in diagnosis,

treatment, and in the organizing of institutions, which had already done much better work than many had expected.

Clause V of the bill takes up the old provisions against sexual intercourse by persons suffering from venereal disease, and has a new subsection, as under:

(3) A person charged with an offence under this regulation shall if he so requires be remanded for a period (not less than a week) for the purpose of such medical examination as may be requisite for ascertaining whether he is suffering from such a disease as aforesaid. The defendant shall be informed of his right to be remanded as aforesaid, and that he may be examined by his own doctor or by the medical officer of the prison.

By Clause VI an offence under the previous clause is added to the list of offences which afford ground for judicial separation for women. Clause VII is designed to consolidate and amend the Indecent Advertisement Act of 1889, and the Venereal Diseases Act of last session.

Army Medical Service Report (France).—Major David Davies asked Mr. Maopherson on May 2nd whether, in view of the increased demands upon the medical man power of the country, he would take immediate steps to present to the House the report of the committee of inquiry into the medical service in France. Mr. Maopherson replied: In the opinion of the recognized heads of the civil medical profession there is nothing in the report on which action is likely to be taken affecting the medical man power of this country. As I informed my hon. and gallant friend on April 23rd, consideration of the report has had to be suspended during the present emergency. It is not proposed to publish the report.

Medical Students and National Service.—A full statement as to the position of medical students in regard to national service was made by Mr. Beck, on May 2nd, in reply to a question by Mr. Snowden. He said that it was determined by National Service Instruction 35 of 1918 and Army Council Instruction 153 of 1918. These instructions were summarized in the JOURNAL of March 16th and February 23rd respectively. Mr. Beck added that medical students who did not fulfil the conditions of exemption were posted to the army in the ordinary way and not necessarily to the R.A.M.C.

Medical Men's Chauffeurs.—Sir Watson Cheyne asked whether chauffeurs employed by medical men carrying on large general practices, not only of their own, but also of medical men serving in the army and very dependent on their experienced drivers, might be exempted from military service. Mr. Beck replied that the Decertification Order of April 9th applied to chauffeurs within the age and medical category stated, but that a certain discretion was vested in National Service representatives to be exercised in urgent and exceptional cases until an efficient substitute had been found. It could not be too strongly urged that all motor drivers fit for military service should be replaced at the earliest moment by women, by unfit men, or by men discharged from the forces.

Indian Medical Service.—On an inquiry by General Page Croft, on May 8th, Mr. Herbert Fisher said that, as a special measure, the Secretary for India last December authorized the ante-dating of the promotion of certain captains of the Indian Medical Service with a view to securing for them a relative equality in seniority with that of corresponding officers of the Royal Army Medical Corps whose promotion had been accelerated by war conditions.

Voluntary Red Cross Workers.—The position under the Military Service Act of voluntary Red Cross workers who convey wounded soldiers from railway stations to hospitals was explained by Mr. Beck on May 2nd. The Army Form O 337 was a certificate of identity issued by the War Office to civilians wearing Red Cross brassards, and conferred no exemption or protection from military service. Men certified as full-time workers by the British Red Cross Society whose engagement had been sanctioned by the Director of National Service in the region were not called to the colours under present instruction if placed in Grade 3. It was intended that men now liable for service by the raising of the military age should have this protection if they fulfilled the above conditions.

National Service Grading.—Mr. Beck informed Mr. Anderson that the standard of medical grading by National Medical Boards had not been altered, except that a slightly lower standard of vision had been adopted in accordance with the views expressed by a committee of military and civil ophthalmic specialists.

Examinations by Medical Boards.—In reply to Mr. Cathcart Watson, Mr. Beck, on May 1st, said that under present arrangements for the medical examination of recruits every effort was made not only to obtain evidence of each man's medical history but to weigh this evidence carefully before deciding on a man's grading.

Supplemental Rations.—Mr. Clynes, the Parliamentary Secretary to the Food Department, said, on May 3rd, that it was not at present possible to state the number of persons who were obtaining a higher scale of food rations. So far as civilians were concerned heavy manual workers obtained two extra meat coupons a week, and these were valid for the purchase of any meat other than uncooked butcher's meat. There was no differentiation of rations between different classes of heavy workers. A certain number of women and children were included in this class. Adolescent boys from 13 to 18 obtained half the amount, while an additional meat meal was provided for persons working a specified amount of overtime at night after a full day. The Food Control Committees were ordinarily the deciding authorities, but acted under general instructions from the Ministry of Food. The arrangements were provisional.

THE WAR.

TREATMENT OF WOUNDS IN WAR.

(Concluded from p. 516.)

THE following are the final sections of the conclusions of the Inter-Allied Surgical Congress at Val-de-Grâce from March 11th to 16th.

IV. TREATMENT OF PSEUDARTHROSIS.

1. The unavoidable cause of false joints in war fractures is the primary destruction of a part of the diaphysis. The other causes which actually have to be taken into account are infection, excessive removal of splinters of bone, and bad reduction, and these ought to disappear. A certain number of false joints can be avoided by sterilization of the seat of fracture, prudent removal of fragments of bone, good reduction carefully supervised, and in certain well-defined cases by immediate or early fixation of the bones.

2. Save in exceptional cases, false joints should only be operated upon after a considerable interval, when the skin wound is completely cicatrized and when clinically the inflammatory process appears to have ceased. The existence of buried organisms should be investigated by all means at our disposal, such as forcible active and passive movements, elastic bands, vigorous massage, etc.

The following note is added at the request of Sir Arbuthnot Lane:

(a) In cases in which the lower end of the femur, or the upper end of the tibia, or both, are removed the treatment may differ according to the occupation of the wounded man. In workmen an attempt should be made to obtain ankylosis between the femur and tibia either directly or by means of a graft; in men following sedentary occupations a false joint fixed by an apparatus which permits of flexion may be more advantageous. Either of these two conditions is preferable to amputation of the thigh and an artificial limb. (b) In a case in which there has been extensive loss of substance of the lower end of the humerus, the elbow being intact, it is often desirable to obtain a false joint permitting flexion between the humerus and its shattered lower end, leaving rotation to be produced at the radio-humeral articulation. This condition is more useful and permanent than that given by resection of the elbow.

3. From the point of view of treatment two conditions are to be distinguished: (a) In simple false joints and in certain examples of false joint with loss of substance in the part of a limb containing only a single bone, it is possible, after freshening the bone in the manner that pathological anatomy suggests, to unite the bones by a metal plate. The best method appears to be fixation with a metal plate, using screws, the screws being placed as far as possible from the false joint. The combination of the use of the metal plate and of an osteo-periosteal graft has given very good results. (b) A false joint with loss of bony substance usually requires a bony or osteo-periosteal graft.

4. Perfect asepsis. Complete excision of the fibrous tissue which surrounds the fragments and of any diseased portions of the bones are conditions indispensable to success.

The following note is added at the request of Sir Arbuthnot Lane: An additional means of detecting and eliminating the persistence of infection is the use of autogenous or stock vaccine.

V. CONSERVATIVE OPERATIONS ON THE FOOT.

As it is very desirable to maintain the integrity of the sole, incisions or resections through it should only be performed when absolutely necessary. Every endeavour should be made to obtain primary union in every case. The same considerations apply to the dorsal surface of the foot when cicatricial contraction might interfere with the functions of the sole of the foot. It is even justifiable to resect certain bones in order to permit primary or secondary union and the maintenance of the skin of the sole in its normal condition. Amputation of one or several toes causes little inconvenience. The preservation of one toe, especially the first or the fifth, is often embarrassing. Disarticulation of the metatarsal bones, with preservation of

the corresponding toes, generally gives bad results. Resection of the first and fifth toes, with their metatarsal bones, generally gives a satisfactory result. The result of preservation of the great toe alone, with its metatarsal bone, is not generally good. Excision of the second, third, and fourth metatarsals produces a narrow foot, and walking and standing are seriously impeded. As a general rule the loss of three metatarsal bones seriously upsets the mechanism of the foot. The results of amputation through the metatarsus with a good plantar flap, whether performed through the anterior or posterior part of the metatarsus, are very favourable. After Lisfranc's disarticulation walking may be easy and even elastic if the remainder of the foot is in good condition. As it is a difficult operation, it may be simplified by leaving the bases of the metatarsal bones. Pre-scapheoido-cuboid amputation gives good functional results. In short, all the operations through the front of the tarsus give good results if there be no complication due to the cicatrix or the conditions of the articulations. Chopart's amputation when done under good conditions and carefully watched may give a good result, but the equinism and the displacement of the stump often cause functional troubles which render it inferior to the amputations of Lisfranc and Syme. Partial resections of the astragalus and calcaneum, or horizontal resection of the calcaneum, check the tendency to equinism. Amputation below the astragalus (Pirogoff's amputation and more especially Syme's) leaves the patient able to walk easily and quickly. On the other hand, operations on the posterior tarsus are very often followed by functional difficulties. Total or subtotal excision of the astragalus gives good results, but they are not so good as those obtained in peace; the causes of failure are infection of neighbouring tissues, stiffness of joints and tendons, and insufficient supervision of the attitude of the foot after operation. Excision of the whole or greater part of the calcaneum, if bony regeneration does not take place, leaves a bad condition, very frequently attended by tibio-tarsal or mediotalar ankylosis. Partial resections, whether posterior or inferior, give less unfavourable results if the foot is well maintained at a right angle during the whole course of treatment. Combined resection of the calcaneum and the astragalus gives usually a bad result.

Atypical Operations.—Resections of the anterior part of the tarsus involving the scaphoid and cuboid are often followed by equinism, with valgus or varus, or falling in of the arch of the foot. The functional condition can be greatly improved by an orthopaedic boot. The seriousness of the consequences of excision of either of these bones seems to be about equally great. The results of atypical operations on several bones of the anterior part of the tarsus are determined much more by the degree of preservation of the arch of the foot, the strength of the points of contact of the sole with the ground, and the preservation of the action of joints and tendons than on the site of the operation itself. Vicious positions of the foot, if the joints be freely movable, can be cured or improved by the division or transplantation of tendons. Transplantations are particularly useful when certain tendons have been destroyed. Some vicious positions with ankylosis call for secondary operations on the bones (resection of the cuneiform or astragalus). In short, conservative operations on the metatarsus are good, but in the posterior tarsus excision of the calcaneum or resection of several bones often cause functional disturbances which are graver than those following disarticulation or a Syme's amputation.

Note.—Professor Depage points out that in suppuration of the joints of the tarsus, persisting in spite of excision of the astragalus, an operation turning the foot forwards and inwards by extensive section of tendons and ligaments, and the maintenance of the position by means of a bandage, favours disinfection of the suppurating focus. The foot can be replaced in the normal position after a week or a fortnight.

VI. FIXATION OF COMPOUND FRACTURES.

A distinction must be drawn between a primary operation for fixation of a compound fracture and an operation performed during the period of infection.

Primary Fixation.—The possibility of applying primary suture or delayed primary suture to a great number of wounds complicated by fracture justifies in principle the

immediate fixation of compound fractures, but the indications for the operation are uncommon. They are:

1. In certain fractures of joints in which the operation appears to be a method of choice to obtain anatomical and functional restoration.

2. In fractures of shafts which are irreducible or cannot be maintained in correct reduction (especially subcondylar fractures of the femur, fractures of the arm, etc.), and when large displaced fragments of bone are present.

Modern improvements in splints, however, render it possible in the majority of cases to obtain satisfactory adjustment without a fixation operation. Primary fixation is a difficult operation which exposes the patient to grave complications; it should be performed only by surgeons who have specialized, and at the present time the indications for it are uncommon. In the British army it is not the custom to have recourse to a primary fixation operation, for two reasons: (1) The good results now obtained with splints; (2) the bad results which fixation operations have often given in the past.

Fixation during Infection.—Operation for fixation during infection is accepted by some, but expressly rejected by others; those who accept it hold that it lessens the infection at the seat of fracture, is not accompanied by prolonged osteomyelitis, and is rarely attended by secondary sequestra. The results obtained, as a whole, are favourable. The indications for the operation would be the impossibility of reducing certain fractures of shafts or of maintaining them in correct reduction. Nevertheless, modern improvements in splints render possible such satisfactory reduction that fixation by operation is rarely indicated. Temporary fixation by means of plates and screws commands a majority of suffrages.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON H. N. DALE-RICHARDS, R.N.

Surgeon Hedley Norman Dale-Richards, R.N., was reported as killed in action, in the casualty list published on May 1st. He was educated at St. Mary's Hospital, and graduated B.Sc.Lond. in 1912, after which he held the posts of joint lecturer in biology and senior demonstrator in physiology in the Middlesex Hospital Medical School. In 1917 he took the diploma of L.M.S.S.A., and immediately joined the navy as a temporary surgeon.

SURGEON PROBATIONER W. C. HOLDSWORTH, R.N.V.R.

Surgeon Probationer W. C. Holdsworth, R.N.V.R., was reported as killed in action, in the casualty list published on May 1st. He had previously been reported as "missing, presumed killed," in the loss of H.M.S. *Begonia* in October, 1917.

Died of Injuries.

SURGEON R. W. BRANDER, R.N.

Surgeon Robert William Brander, R.N., died of accidental injuries at South Queensferry Naval Hospital on May 1st. While returning on a motor cycle from duty at Burntisland he was run into by a train of wagons at a siding at Rosyth. He was the son of Mr. Brander of Cupar, Fife, and was educated at the University of Glasgow, where he graduated M.B. and Ch.B. in 1914, and served as resident assistant to the Regius Professor there, till he took a temporary commission in the navy. For fifteen months he was surgeon on a cruiser in the North Sea, and afterwards served for eight months as house-surgeon at the Marchioness of Bute's naval hospital at Mount Stuart, Rothersey. Subsequently he was surgeon on a cruiser in the West Indies and the Atlantic.

ARMY.

Killed in Action.

CAPTAIN T. J. FEHILY, R.A.M.C.

Captain Thomas Joseph Fehily, R.A.M.C., was reported as killed in action, in the casualty list published on May 3rd. He was educated at Queen's College, Cork, and in the medical school of the Royal College of Surgeons, Ireland, and took the Irish double qualification in 1908 and the D.P.H. of the R.C.S.I., in 1910. After serving as house-surgeon at Jarvis Street Hospital, Dublin, and as assistant

medical officer and pathologist at the Devonshire County Asylum at Exminster, he became assistant medical officer at the Lancashire County Asylum at Rainhill. He took a temporary commission as lieutenant in the R.A.M.C. on October 10th, 1914, and was promoted to captain after a year's service.

CAPTAIN R. S. KENNEDY, M.C., R.A.M.C.

Captain Ronald Sinclair Kennedy, M.C., R.A.M.C., was reported as killed in action, in the casualty list published on May 6th. He was educated at Guy's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1912, and at Cambridge, where he graduated B.A., M.B., and B.C. in 1913, and M.D. in 1917. He entered the Egyptian service, where he successively filled the posts of ophthalmic surgeon to the Daquahia Provincial Hospital, and of inspector of ankylostoma hospitals, till he took a temporary commission in the R.A.M.C. towards the end of 1916, being promoted to captain after a year's service. He received the Military Cross on September 26th, 1917, and was recently attached to the South Lancashire Regiment.

CAPTAIN I. KEITH-FALCONER MACLEOD, R.A.M.C.

Captain Ion Keith-Falconer MacLeod, R.A.M.C., was killed in action on April 27th. He was the only son of the Rev. D. J. MacLeod, of the United Free Church Manse, Boddam, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1914. After serving as resident house-surgeon in the Edinburgh Royal Infirmary, he joined the R.A.M.C. as a temporary lieutenant, and was promoted to captain a year later.

CAPTAIN H. E. ROBINSON, R.A.M.C.

Captain Henry Ellis Robinson, R.A.M.C., attached West Yorkshire Regiment, was killed on April 26th, aged 31. He was the fourth son of the Rev. E. C. Robinson, of Malvern, formerly of Haubury, Staffordshire, and was educated at St. Bartholomew's Hospital, obtaining the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1915. Shortly after, he took a temporary commission as lieutenant in the R.A.M.C. and became captain a year later.

Died on Service.

CAPTAIN H. G. MASSY-MILES, R.A.M.C.

Captain Harry Godfrey Massy-Miles, R.A.M.C., died on service on April 26th, aged 32. He was the eldest son of the Rev. Canon J. H. Miles, of Teignmouth, and was educated in the medical school of the Royal College of Surgeons, Ireland, taking the diplomas of L.R.C.S.I. and L.R.C.P.I. in 1909. After acting as extern maternity assistant at the Rotunda Hospital, Dublin, and as house-surgeon of Fermanagh County Hospital, he went into practice at Trafford Park, Manchester. He took a temporary commission as lieutenant in the R.A.M.C. on December 21st, 1914, and was promoted to captain after a year's service.

Died of Wounds.

MAJOR W. S. GARNETT, A.A.M.O.

Major W. S. Garnett, Australian Army Medical Corps, was reported as having died of wounds, in the casualty list published on May 3rd. He had previously been reported as wounded in that of April 30th.

CAPTAIN H. S. PALMER, R.A.M.C.(T.F.).

Captain Hugh Salisbury Palmer, R.A.M.C.(T.F.), died of wounds on April 25th, aged 30. He was the younger son of the late Mr. C. A. Palmer, of Norwich, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1914. He took a commission as lieutenant in the 1st Home Counties (Maidstone) Field Ambulance on November 10th, 1914, and had subsequently served as medical officer to the 2nd Battalion Rifle Brigade, and in the 2/2nd Home Counties Field Ambulance.

CAPTAIN C. E. A. WILSON, R.A.M.C.

In the JOURNAL of April 30th we printed an obituary notice of the late Captain C. E. A. Wilson, who died of wounds on April 8th. A former teacher states that Captain Wilson received his fatal wound in the spine whilst attending the wounded under heavy fire; in spite of the gravity of his condition he insisted upon others being attended to first. He had previously been recommended for the Military Cross for conspicuous courage. Wilson achieved

the rapid success in practice which his professional ability, devotion to work, and kindness of disposition could not fail to bring. He was a man of high ideals and culture, combined with a modest and unassuming demeanour; a delightful companion and a staunch friend.

Wounded.

Lieut.-Colonel A. L. G. Gilday, Canadian A.M.C.
Major J. B. Lowe, R.A.M.C. (temporary).
Major J. Purdie, M.C., R.A.M.C. (S.R.).
Major A. W. Rattrie, R.A.M.C. (temporary).
Brevet-Major N. W. Stevens, R.A.M.C.
Captain E. S. Cathbert, R.A.M.C. (temporary).
Captain G. Fleming, R.A.M.C. (temporary).
Captain W. A. N. Fox, R.A.M.C. (S.R.).
Captain H. L. Gauntlett, R.A.M.C. (T.F.).
Captain F. C. Harrison, R.A.M.C. (S.R.).
Captain J. G. Hill, R.A.M.C. (T.F.).
Captain C. H. Leeman, M.C., Australian A.M.C.
Captain G. T. MacLean, R.A.M.C. (temporary).
Captain A. Malseed, M.C., R.A.M.C. (temporary).
Captain O. D. B. Mawson, R.A.M.C. (temporary).
Captain A. F. L. Shields, R.A.M.C. (S.R.).
Captain C. G. Skinner, R.A.M.C. (temporary).
Captain P. R. Woodhouse, M.C., R.A.M.C. (temporary).
Lieutenant G. L. Gall, R.A.M.C. (temporary).
Lieutenant and Quartermaster W. Gough, R.A.M.C.

Wounded and Missing.

Captain R. D. MacGregor, R.A.M.C. (temporary).

Missing.

Captain A. G. Clark, M.C., R.A.M.C. (temporary).
Captain S. A. Forbes, R.A.M.C. (temporary).
Captain C. C. Gibson, R.A.M.C. (temporary).
Captain A. H. Little, R.A.M.C. (T.F.).
Captain J. P. Macvoy, R.A.M.C. (temporary).
Captain C. O'Malley, R.A.M.C. (temporary).
Captain H. W. White, R.A.M.C. (temporary).

Prisoners of War.

Captain T. E. Carr, R.A.M.C. (temporary).
Captain H. Cranweller, R.A.M.C. (temporary).
Captain E. H. Griffin, D.S.O., M.C., R.A.M.C. (temporary).
Captain R. W. Hodgson-Jones, R.A.M.C. (temporary).
Captain A. T. I. Macdonald, R.A.M.C. (temporary).
Captain J. G. M. Molony, R.A.M.C. (temporary).
Captain J. C. Muir, R.A.M.C. (temporary).
Captain S. Smith, R.A.M.C. (temporary).
Captain J. Tate, R.A.M.C. (temporary).

Captain E. H. Griffin, D.S.O., was previously reported as killed; a notice of his services was published in the *BRITISH MEDICAL JOURNAL* of April 13th.

DEATHS OF SONS OF MEDICAL MEN.

Baker, Harold Glasspool, Captain, M.C., 8th Somerset Light Infantry, second son of Dr. Thomas Baker of Waterlooville, Hants, aged 28, killed April 5th. He gained the M.C. and bar in 1917.

Boucher, Henry Mason, Captain Somerset Light Infantry, only surviving son of the late Dr. Arthur Henry Boucher of Hertford, killed April 23rd, aged 27. He got a commission on March 24th, 1915.

Crerar, Donald Campbell, Lieutenant R.F.A., attached R.E., fifth surviving son of the late Dr. John Crerar of Maryport, killed April 24th, aged 34. He got a commission in the Cumberland howitzer battery of the 4th East Lancashire Brigade of Artillery (T.F.) on February 28th, 1915.

Culpin, Clarence H., Australian Infantry, son of Dr. M. Culpin of Taringa, Brisbane, Queensland, killed in France on April 16th.

Cunnington, Lieutenant C. H., eldest son of Dr. Cunningham of West End Lane, Hampstead, died on April 26th from illness contracted on active service. At University College, London, he took first class honours and gained the University scholarship in geology. Subsequently he was appointed assistant geologist in the Geological Survey. He obtained his commission in the 8th Wilts and subsequently was sent to the Dardanelles as geological expert attached to the Royal Engineers, and while there suffered a severe illness. On returning to England, he joined a machine gun corps and went to France in February, 1917, but was invalided out of the army in October. After an operation he resumed his work for the Survey, but his health again broke down last month.

Grange, James Burness, Second Lieutenant West Yorkshire Regiment, youngest son of Dr. J. D'Oyley Grange of Harrogate, formerly of Moffat, killed April 20th. He was educated at Repton and at Guelph Agricultural College, Canada, where he graduated B.Sc. Returning to England, he got a commission

through the Ions of Court O.T.C., and went to the front about a year ago.

Millar, Arthur Liberty, Captain Rifle Brigade, only son of Dr. James Millar of Nottingham, killed April 15th. He got his first commission on November 21st, 1914.

Palmer, Edwin, Lance-Corporal London Regiment, youngest son of the late Dr. Grimes Palmer of Loughborough, Leicestershire, reported missing June 15th, 1917, now presumed killed on that date.

Peskett, Guy Eastwood Harry, Second Lieutenant Duke of Wellington's West Riding Regiment, eldest son of the late Dr. A. W. Chalmers Peskett, reported missing on May 3rd, 1917, now presumed killed on that date, aged 25. He was born in September, 1883, became a chartered accountant, got his commission in October, 1915, and went to the front in January, 1917.

Saunders, Robert Stratford Howard, Lieutenant R.F.A., only son of Captain Charles Howard Saunders, R.A.M.C. (T.F.), of Southampton, died of wounds on April 12th, aged 19. He was educated at Marlborough, entered Woolwich in 1915, got his commission in May, 1916, and was promoted to lieutenant in November, 1917. His father is now serving with the Italian Expeditionary Force.

Snell, Eric Aylmer Goldney, Major Bedfordshire Regiment, only son of Dr. G. Snell, late of the Colonial Medical Service, killed in German East Africa on November 16th, 1917. He was born in 1892, educated at Bedford School, and got his commission through Sandhurst in 1912. In March, 1914, he was appointed an assistant commissioner in Uganda, and when war broke out was posted to the King's African Rifles. He served in the Sudan, at Khartoum, in the Belgian Congo, and on the White Nile, and raised a new battalion of the K.A.R. He became captain in the Bedfords in 1916, major in the K.A.R. in 1917, and was mentioned in despatches on March 27th, 1918.

Stanton, Robert G., Lieutenant Royal Marines, eldest son of Dr. Stanton, of Market Deeping, South Lincolnshire, died at Dover of wounds received in the attack on Zeebrugge on St. George's Day, April 23rd.

Tuzo, John Atkinson, Captain Royal Sussex Regiment, son of the late Dr. Henry Atkinson Tuzo of Warlingham, Surrey, died in East Africa on April 8th, aged 43. His commission as captain in the 6th (Cyclist) Territorial Battalion of the Royal Sussex was dated April 15th, 1915.

Second Lieutenant S. Jackson (acting Captain), 2nd Battalion West Yorks Regiment, only son of Mr. H. L. Jackson (of Messrs. H. K. Lewis and Co., Ltd.), is reported missing since April 24th. He enlisted as a private in the R.A.M.C. (T.), in 1914, was transferred to an O.T.C. in January, 1917, gained his commission in May, and went to France in July of that year.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL Supplement to the *London Gazette*, dated April 25th, contained the following statements of conspicuous gallantry and devotion to duty for which the awards indicated have recently been granted:

Bar to the Distinguished Service Order.

Temporary Surgeon William James McCracken, D.S.O., M.C., R.N.

He tended and evacuated the wounded in the open under heavy shelling. Hearing that there were many wounded lying in mud and water in shell holes, he led up two platoons with stretchers. When they were fired on he made them take cover and himself advanced through the enemy's fire, bearing a Red Cross flag on his walking stick. This the enemy eventually respected, and so he was able to clear the area of wounded. By his courageous action he saved many lives.

Distinguished Service Order.

Temporary Captain Archibald Stirling Kennedy Anderson, M.C., R.A.M.C.

Under heavy shell fire he led forward a party of stretcher-bearers and collected twenty-five wounded men who were lying within fifty yards of the enemy line. He set a splendid example of courage and self-sacrifice.

Temporary Captain James Thornley Bowman, R.A.M.C.

During an attack he attended to the wounded for five hours in the open under heavy fire. He showed the greatest coolness and courage throughout the day.

Captain George Vernon Davies, A.A.M.C.

He went forward through an intense barrage and established a regimental aid post in an advanced position, remaining on duty continuously for fifty-four hours, often working in the open under heavy fire. When the aid post was hit by a shell he extricated a man who was buried, and continued his work. He remained for fifteen hours after the battalion was relieved till the last man was carried back to safety, and set a magnificent example to all.

Temporary Captain Howard Boyd Graham, R.A.M.C.

During a heavy barrage he personally reconnoitred the advanced aid posts, with the result that many cases were evacuated the moment the barrage lifted. This action undoubtedly saved many lives. On another occasion he went out and brought in two officers and four other ranks who were lying out unattended. Later, hearing that an officer had become a casualty, he went forward and brought him back single-handed to a point whence he was evacuated. His coolness, fearlessness, and devotion to duty were beyond praise.

Captain (acting Lieut.-Colonel) Robert Thin Craig Robertson, R.A.M.C.(S.R.).

When two ammunition lorries were hit by enemy shells he went forward at great risk to where several men had been killed or wounded, dressed their wounds, and had them evacuated. He displayed great initiative and coolness.

Temporary Captain Harvey Gordon Young, C.A.M.C.

During an attack he went forward with a stretcher squad through a heavy barrage and established an advanced aid post. For two days he was entering in his work of attending to the wounded, and getting them in from advanced areas with complete disregard of danger. By his skilful organization and untiring energy he attended to and evacuated over 400 cases in two days.

Second Bar to the Military Cross.

Temporary Captain George D'Rastrik Carr, M.C., R.A.M.C.

He reconnoitred a route for his bearers under heavy shelling. From 4 a.m. till late the following evening he was continually under heavy fire between his collecting post and the regimental aid post. His constant knowledge of events in the first line enabled only the requisite number of bearers to be used in the more dangerous parts.

Bar to the Military Cross.

Temporary Surgeon James Ness McBean Ross, M.C., R.N.

He attended the wounded in the front line under heavy fire, until himself severely wounded.

Captain David MacDonald Steele, M.C., A.A.M.C.

He was in charge of the evacuation of the wounded from a whole divisional front during thirteen days' operations. On several occasions, when it was impossible to bring casualties through by the existing route, he personally inspected the new line of evacuation on each occasion, and made admirable arrangements for getting them clear and avoiding further casualties.

Captain Robert Bell Stewart, M.C., R.A.M.C.(S.R.)

He successfully carried out the evacuation of the wounded from the regimental aid post, over extremely bad ground, and under very heavy fire.

Temporary Captain Francis Ruthven Thornton, M.C., R.A.M.C.

When in charge of bearers he evacuated the wounded under very adverse weather conditions. When, owing to an intense barrage, bearers repeatedly failed to get through to the advanced regimental aid post, he personally led them forward and remained there for ten hours, evacuating thirty-six serious cases.

Military Cross.

Temporary Captain John Frederick Broughton, R.A.M.C.

He attended the wounded in an exposed aid post under heavy fire throughout the day. He visited the advanced positions whenever he could to organize his bearers and collect wounded. After the battalion was relieved he stayed in the line all the following day to search for wounded. When the medical officer of a neighbouring battalion became a casualty he passed from one aid post to the other under heavy fire and attended to the wounded of both battalions.

Captain Angus Cameron, R.A.M.C.

He attended to the wounded under constant shell fire, during which his regimental aid post was blown up, and he had to continue his work in the open. After heavy casualties had occurred among the stretcher-bearers he organized stretcher parties from all available men, and carried in wounded men himself.

Temporary Lieutenant (temporary Captain) William Kealty Campbell, D.S.O., R.A.M.C.

In searching for wounded he and his party came under heavy fire. Ordering his bearers to take cover in shell holes, he searched the ground by himself, calling up bearers as he required them. When moving away with the last wounded man a shell severely wounded one of the bearers. Ordering the remainder to take their stretcher case into a "pill-box," he remained in the open with the wounded bearer till he died.

Temporary Captain Charles Lauder Chalk, R.A.M.C.

He displayed great initiative under shell fire. When his dressing station was crowded with wounded he dressed in the open those who were unable to find cover. Through his promptitude and headlessness of danger in dressing and clearing away the wounded he undoubtedly saved many lives during a critical period.

Captain Archibald John Collins, A.A.M.C.

He organized a party of forty stretcher-bearers, leading them through two barrages to the front line, and dressing and attending wounded under heavy fire and direct observation.

Captain Joseph Wilfrid Craven, R.A.M.C.

When in charge of bearer parties removing the wounded he discovered many wounded in an old enemy "pill-box," he returned for bearers, and so saved the lives of one officer and six men. During the whole time he was under severe machine-gun fire and shrapnel.

Captain Henry Clarke Davis, C.A.M.C.

He was continually on duty as regimental medical officer for four days and nights, under heavy fire, attending to the wounded, and frequently dressed cases in the open. His courage and determination were responsible for the evacuation of all the wounded before the battalion was relieved.

Temporary Captain Henzell Howard Dummere, R.A.M.C.

He voluntarily left shelter and went across difficult ground under very heavy fire to help three seriously wounded men, afterwards conducting the stretcher-bearers to the aid post half a mile away.

Captain Eric Macallan Gordon-Glassford, A.A.M.C.

He attended the wounded under intense shell fire. Finding a squad of bearers exhausted owing to the mud, he and his orderly relieved two of them and helped to carry a wounded man for three miles under shell fire. Finding that a dog-out had been hit and three men buried, he went with a couple of bearers, and, in spite of heavy shell fire, succeeded in extricating the men and getting them away.

Captain Hugh Edward Kirkland, A.A.M.C.

When the enemy concentrated a heavy fire on a battery, one officer and five men being wounded, he went out at great personal risk under this fire and got them to a place of safety.

Captain Guy Ardlaw Lawrance, A.A.M.C.

In addition to his ordinary regimental duties he accompanied a daily convoy of thirty G.S. wagons detailed for road repair. He attended to the wounded in the open irrespective of units, under extreme difficulties and heavy shell fire.

Temporary Captain John Tryweryn Lloyd, R.A.M.C.

As battalion medical officer he frequently went forward under heavy machine-gun and shell fire to supervise the work of his stretcher-bearers.

Captain Alfred James Angel McCabe Dallas, R.A.M.C.

Seeing a trench some distance off being heavily shelled, although not in medical charge of the troops occupying it, he at once ran to see if he could help any casualties, and while so doing was severely wounded.

Temporary Captain James MacGregor, R.A.M.C.

When in charge of a bearer division he followed up the barrage closely and evacuated the wounded under heavy fire. By magnificent work he cleared the ground of wounded before dusk.

Temporary Captain James Murdoch MacKay, R.A.M.C.

He remained at work although suffering from gas poisoning and continually left the aid post to direct his orderlies and bring in walking wounded cases.

Captain John Shaw Mackay, A.A.M.C.

When in command of bearer division he attended to many casualties which occurred amongst the personnel of batteries and working parties, carrying out his duties in the open with utter disregard of danger.

Captain Philip McRitchie, R.A.M.C.

Coming upon a party of sixteen men wounded by shell fire, he dressed their wounds under a heavy barrage and called for volunteers to carry them to the aid post. Hearing that his commanding officer and adjutant had been wounded about a mile away, he made his way across country under heavy fire and got them to the dressing station.

Captain Melrose Holton Moller, A.A.M.C.

He worked for forty-eight hours attending the wounded in the open under most difficult conditions and heavy shell fire.

Captain James Frederick Stewart Marshall, C.A.M.C.

Hearing that there were many wounded in "No Man's Land," he called for volunteers and went forward in charge of them under intense fire. He was continuously on duty for forty-eight hours, and brought in many wounded under most trying conditions.

Temporary Lieutenant Kekbasu Sobrabji Master, I.M.S.

He pushed forward his advanced dressing station and kept in close touch with the regimental aid posts, and collected, dressed and evacuated the wounded. He showed great courage and coolness under heavy fire.

Temporary Captain David Matthew, R.A.M.C.

During two days' heavy fighting he established a dressing station in an advanced position whence he continually went forward to dress wounded and organize carrying parties under heavy fire. He inspired his men to continue their work by his splendid example.

Captain Thomas Williamson Moore, C.A.M.C.

When in charge of bearer parties at an advanced regimental aid post cases had to be attended to in the open under heavy fire, and he worked continuously for forty-eight hours.

Captain Edgar Percival, D.S.O., R.A.M.C.

While he was leading a party of sixteen stretcher-bearers towards the aid post they came under heavy shell fire, and seven were wounded. He got them back and brought up fresh men. One of this party was wounded, and while an attempt was being made to get him back the patient and three bearers were killed. After replacing these casualties he succeeded in getting through at the third attempt, and removed all the wounded.

Temporary Captain Maurice Aloysius Power, R.A.M.C.

When in charge of a bearer division, he collected and dressed wounded under heavy fire. On the way to the aid post his bearer was killed by a shell and he was wounded, but he succeeded in clearing his sector of wounded before dark, and then had to be assisted in an exhausted condition to the dressing station.

Captain Henry Frederick Preston, C.A.M.C.

As regimental medical officer he established an aid post in a most advanced position, and worked under continuous shell fire. He set a magnificent example by his coolness and courage, and his fearlessness and untiring energy saved many lives.

Captain William Dempsey Quilty, A.A.M.C.

When in charge of a bearer division he remained at a cross roads throughout the day attending to casualties and supervising their evacuation, though the enemy was persistently shelling the area with gas and high explosive shells.

Temporary Captain Reginald Thompson Raine, R.A.M.C.

During an intense barrage he went out in the open to attend to wounded, and when his stretcher-bearers became casualties he himself carried cases in. Returning later, he also brought in the stretcher-bearers, though exposed all the while to an intense shell fire. He showed a magnificent example to all, and undoubtedly saved many lives.

Captain Clive Frederic Robinson, A.A.M.C.

On hearing, while with another battery, that two batteries 500 yards away were being heavily shelled with gas, shrapnel, and high explosive shells, and many casualties were occurring, he at once went there, and, in spite of the intensity of the shelling, remained for an hour and a half attending to the wounded.

Captain Christopher Rogers, R.A.M.C.

As medical officer to his battalion during an attack, when his aid post was blown in and all his staff killed or wounded, he remained at his post, working in the open under continuous shell fire over twenty hours, 200 cases passing through his hands. After most of his stretcher-bearers had been killed or wounded, he brought in a large number of wounded himself until he was exhausted.

Captain John Gray Ronaldson, R.A.M.C.(S.R.).

He was in charge of bearers for nine days, almost without rest. He several times went forward under heavy shell fire to attend to gunners who were wounded and lying in the open. During a heavy gas bombardment, in which there were many casualties, he was himself gassed.

Captain Walter Hepburn Scott, C.A.M.C.

He led his stretcher-bearers forward over "No Man's Land" and dressed and brought in many wounded men under very heavy fire. Although buried and severely shaken by a shell, he continued his work.

Temporary Captain Reginald Herman Tribe, R.A.M.C.

Having organized an aid post behind the front line, he dealt untiringly with many wounded cases belonging to several different units, his courage and efforts being the means of saving many lives and much suffering. He showed splendid determination and resource.

Captain Ernest Coultter Whitehouse, C.A.M.C.

He attended to the wounded under heavy fire, going out repeatedly to bring in wounded officers and men.

NOTES.

**VACCINES PREPARED AT THE VACCINE DEPARTMENT,
ROYAL ARMY MEDICAL COLLEGE.**

WE are indebted to Lieut.-Colonel D. Harvey, C.M.G., R.A.M.C., for the following information:

Since the outbreak of the war and up to the present time the prophylactic vaccines in use for the inoculation of the troops on the various fronts have been prepared in the vaccine department of the Royal Army Medical College, London.

Typhoid.—Down to December, 1915, a simple typhoid vaccine containing 1,000 million bacilli in 1 c.cm. was employed; the amount of this issued was $4\frac{1}{2}$ million doses of 1 c.cm. In addition, 20,000 c.cm. of a mixed paratyphoid vaccine was issued in 1915. Since January 1st, 1916, T.A.B. vaccine so called—that is, a mixed vaccine of *B. typhosus*, *B. paratyphosus* A, and *B. paratyphosus* B—with a dose of 2,500 million bacilli per cubic centimetre has been used, and of this 14 million doses of 1 c.cm. have been issued.

Cholera.—Of cholera vaccine composed of several strains of *V. cholerae* $5\frac{1}{2}$ million doses of 1 c.cm. have been sent abroad, the dose being 8,000 million vibrios in 1 c.cm.

Dysentery.—A new dysentery vaccine has also been prepared; this consists of a mixture of several strains of the various dysentery bacilli, and is injected along with a dose of a specially prepared serum which neutralizes the toxic properties of the bacilli without interfering with their vaccinating powers; 60,000 c.cm. have been issued mostly to Salonica and Egypt, where its use has been attended with success.

Other Vaccines.—The following vaccines have also been prepared and issued: *B. coli* 22,842 c.cm., *Staphylococcus albus* 30,306 c.cm., *Staphylococcus aureus* 95,967 c.cm., *staphylococcus* (mixed) 62,753 c.cm., acne vaccine 33,736 c.cm., streptococcus vaccine 65,865 c.cm.

Tetanus Antitoxin.—All the tetanus antitoxin and other serums prepared elsewhere is received at the Vaccine Department and issued to the various base dépôts overseas and to hospitals at home. The equivalent of 10 million doses of 500 units of tetanus serum has been dispatched.

Preparation and Dispatch.—The total amount of vaccine prepared and issued, or at present in stock, for the three and a half years of war amounts to 25 million doses of 1 c.cm., equivalent to an average daily output of 20,000 c.cm. The whole of this vaccine has been prepared, standardized, and tested by the medical officers of the department. A large part of the bottling of the vaccines has been carried out by teams of voluntary lady workers, who attend for some hours on certain days, about 70 litres of vaccine being bottled in an afternoon. The vaccine is practically all issued in rubber-capped bottles holding 25 c.cm. and 50 c.cm., about twenty gross a week being used.

A MEETING of delegates from Belgium, France, Great Britain, Serbia, and the United States has decided that the International Surgical Society should be dissolved after the publication of the *Transactions* of the meeting held in New York on April 14th, 1917. Any funds remaining after such publication are to be divided *pro rata* among members. Austrian and German members will receive their share, but moneys belonging to members of other nationalities will be applied to some object of scientific reparation in Belgium. A new society on a similar basis, to be called the Inter-Allied Surgical Society, will be constituted after the war. Surgeons of neutral countries will be eligible for membership.

Ireland.

**PARLIAMENTARY REPRESENTATION OF THE QUEEN'S
UNIVERSITY OF BELFAST.**

It was stated in the issue of April 6th that Sir William Whitla had consented to stand as a candidate for the parliamentary representation of this university. The response to the letter of the secretary of his committee has been most gratifying and enthusiastic; up till now he is practically the only candidate, and the recognition of the claim of the profession to have a medical man filling the seat is widespread. Leaders of all professions are on his committee. There is still some confusion as to who has the right of voting. The Queen's University in Ireland granted degrees up to 1832. This university was then dissolved, and was succeeded by the Royal University of Ireland. Every graduate of the Queen's University became automatically a graduate of the Royal University, and his name was transferred to its roll. On the dissolution of the Royal University in Ireland in 1909, each graduate on its roll had the privilege of deciding whether he would enrol himself as a graduate of the new Queen's University of Belfast, or of the new National University, Dublin. In many cases this right has not been exercised. Unless it be exercised, such graduates of the old Queen's University in Ireland and of its successor, the old Royal University of Ireland, will not have a vote for his university representation. Registration on the roll for a university will not interfere with his right to be registered on the residential franchise in his own district. A woman graduate is entitled to be registered on a university roll on the same conditions as a man if she has attained the age of 30 years. Fortunately, it is still open to any graduate who has not yet registered in the Queen's University of Belfast (or in the National University) to do so before the register closes. He should immediately send a letter to the "Secretary, Queen's University, Belfast," asking to be enrolled as a graduate. No fee or expense attends this procedure. Each graduate thus has the privilege of an extra parliamentary vote for life for the asking of it, provided he acts at once. Medical graduates of the old Queen's University of Ireland, or of the old Royal University of Ireland, who took out their classes in Queen's College, Cork, or Queen's College, Galway, or University College, Dublin, and who do not intend to enrol in the National University, can also be registered as graduates of Queen's University, Belfast, if they state any special grounds for so wishing. The voting is carried out by proxy or post.

Scotland.

DR. NORMAN WALKER has been appointed inspector of anatomy for Scotland in the room of the late Sir James A. Russell, M.B.

CHAIR OF MATERIA MEDICA, EDINBURGH.

Sir Thomas R. Fraser, whose resignation of the chair of materia medica in Edinburgh, which he has held since 1877, was announced last week, will be succeeded by Dr. A. R. Cushny, F.R.S., professor of materia medica and pharmacology in the University of London (University College) since 1905. Professor Cushny, who is the son of the late Rev. John Cushny, of Speymouth, Morayshire, graduated at Aberdeen, M.A. in 1886, M.B., C.M. in 1889, and M.D. in 1892. He was assistant to the professor of pharmacology at Strassburg, 1892-3, and professor of pharmacology in the University of Michigan, Ann Arbor, 1893-1905. He is the author of a well-known textbook of pharmacology and therapeutics, which is in its sixth edition, and of an important monograph on the secretion of the urine, published last year.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At a special meeting of the Scottish Central Midwives Board held recently a report by the local supervising authority on the deaths of two patients from puerperal septicaemia was considered; two certified midwives

appeared in answer to the charges of failure to send for medical assistance, and negligence in keeping registers of cases, records of pulse, temperature, etc., as required by the rules. On the conclusion of the hearing the board deliberated *in camera*. Sir Halliday Croom, the chairman, intimated that the Board had in each case found the charges proved, and had directed that the secretary remove the name from the roll of midwives and cancel the certificate.

England and Wales.

LEICESTER PUBLIC MEDICAL SERVICE.

REFERENCE has been made in these columns on several occasions to the Leicester Public Medical Service, founded largely through the initiative of Dr. Wallace Henry. We have now received a memorandum describing this organization and its work, which has been issued in anticipation of an extension and development of medical arrangements by local authorities under a Ministry of Health. It is claimed that the Leicester system is capable of being adapted to meet future needs upon any lines which are considered desirable. The service was inaugurated on January 1st, 1913, to provide medical attendance for dependants of insured persons and others. There is a central dispensary and office, with eight branch dispensaries in various parts of the town, at most of which there are consulting rooms. Qualified dispensers make up all the prescriptions. Adults pay 2d. a week, and children less—this payment entitling the member to ordinary medical attendance, and drugs, dressings, etc., and domiciliary visits to those unable to attend at surgery or consulting room. Members have choice of doctor on a panel of more than sixty, and are allowed to change their doctor quarterly, or more often in the event of removal to another part of the town. Specialist treatment for eye, ear, nose, and throat is available for a moderate additional fee, and dental treatment is also arranged for. All the friendly societies in Leicester make arrangements on a contract basis for medical treatment upon their uninsured members through the Public Medical Service. At the inception of the service a complaint committee was set up consisting of four representatives of the friendly societies, four representatives of the medical profession—two only of these being active members of the service—with an independent lay chairman; but no complaint has yet been received. Other activities of the Public Medical Service include the dispensing of medicines for the outdoor sick poor of Leicester by arrangement with the guardians and the provision of specialist treatment for children by arrangement with the Education Committee. Near the central dispensary is a hospital with twenty-seven beds and two operating theatres, where members can be attended by their own doctor at an arranged fee. The number of uninsured members exceeds 42,000, and about 190,000 prescriptions are dispensed annually. There is no canvassing. During the absence of many medical men on military service the central and branch organizations have carried through a scheme for arranging medical attendance for the patients of absentees. From the foregoing summary it will be seen that there is force in the claim that the Leicester Public Medical Service provides for its members a wider range of service and choice than is now afforded by the State for insured persons. Hence the Board of Management confidently suggests that a Ministry of Health or other central authority should encourage the continuance and development of work so successfully carried out by voluntary effort for more than five years past.

THE MATERNITY AND CHILD WELFARE BILL.

The London County Council on May 7th adopted the recommendations of a report by its Parliamentary Committee on the Maternity and Child Welfare Bill to the following effect:

1. That the powers and duties of the local authorities should be more specifically stated and not left to be determined wholly by the Local Government Board, and in any case concurrent powers should not be placed upon the council and the metropolitan borough councils;

2. That the bill should be amended so as not to require the appointment of statutory committees, and that if such committees were set up the local authority should have complete

freedom of action as regards matters ancillary (in a wide sense) to the special purpose of the committees;

3. That the powers of the new committees as regards children under 5 years of age who might be eligible for the nursery schools to be established under the Education Bill should be so defined as to prevent competition of authority.

Correspondence.

FUNCTIONAL HEART DISEASE AND RECRUITING.

SIR,—As a member of a medical board, my experience is somewhat different to that of Dr. Drinkwater in his letter of April 27th (p. 494). I do not agree that men who have dilated pupils, marked accentuation of cardiac impulse, and a small compressible pulse are necessarily victims of masturbation. The majority of these cases are due to the cigarette habit, a few are nervous, and a small percentage take drugs to upset their heart.

I have come across similar symptoms in women who are smokers, and I cannot think they are all victims of the vicious habit named in Dr. Drinkwater's letter.—I am, etc.,

Overton, Ellesmere, May 1st.

REGINALD MORETON.

UNIVERSITY REPRESENTATION IN PARLIAMENT.

SIR,—With regard to the reply of the chairman and honorary secretary of a Conservative and Unionist Association formed to secure the election of a member of Parliament for the seven combined universities to my letter published on April 20th, I desire to point out that I did not express my party political views. I objected to any candidate being asked to express his party political views. The universities concerned were never formed for party political purposes; the graduates did not depend on their party political "views" to obtain their degrees; and this association has advanced no arguments to justify the introduction of party politics now. That such a procedure has existed elsewhere in the past is no justification for its continuance. The old idea that party politics alone can govern satisfactorily this country or the empire is dead. The Government contains amongst its members many who are now proving this to be the case.

I never expressed my opinion on the keenness or otherwise of this party political association's candidate for social questions. I have not heard his name as yet. I never proposed "that these official bodies—that is, the senates—should take any part in the matter." I said "those in authority," quite a different grouping. In the medical profession we electors would look to the medical leaders of the universities to combine, and thereby assist us "to crystallize our opinions and actions before it is too late."

I would again urge that my medical co-electors put on one side all candidates who come before them wearing a party political label. Such men will be quickly absorbed by the party they belong to, and our profession, now wishful to be represented in the House, will find it might as well have never asked for or obtained the university vote.

My attention has been drawn to a "Universities Parliamentary Representative Association" (honorary secretary: J. F. Ashby, 9, Shalston Villas, Surbiton, Surrey), which includes amongst its conditions "that, other things being equal, preference be given to a candidate who is not the nominee of any of the old political parties." It might be useful for medical electors to write for further details.

Belfast University is finding a medical candidate without looking to a party in politics for any assistance. Surely the medical graduates in the seven universities can do likewise. Who will start the ball?—I am, etc.,

Hove, Sussex, May 4th.

E. ROWLAND FOTHERGILL.

PHYSICAL DETERIORATION OF BOYS UNDER WAR CONDITIONS.

SIR,—The State is showing great activity in promoting the welfare of infants and school children.

At the present national crisis there is now another class which needs even more careful protection. I refer to boys between the ages of 14 and 18. Living and practising as

I do in a very extensive munition area, I am of opinion that a very large number of youths will be found physically unfit when the time arrives for them to submit themselves to medical examination for military service.

Three to four years of absence of paternal control, of practically unlimited supplies of money and cigarettes, lack of sufficient sleep through frequent cinemas and music halls, and, finally, in many cases a tendency to indulgence in alcoholic drinks, must all exact an inevitable toll on the growing boy. Were it not for my wish to be brief I could give many instances of mere boys becoming physical and moral wrecks, and I have no doubt doctors in other munition areas could relate similar experiences.

Are the authorities aware of what is going on? If so, cannot some means be adopted to mitigate the mischief? For boys of 16 and 17 to be earning and spending three or four pounds a week (in many cases more) is nothing less than demoralization. Too much money is the root of the evil. I would suggest that no one under the age of 18 be allowed to receive more than (say) 30s. a week, and that any wages in excess of this amount be held in trust till the earner returns to civil life.

I commend to the notice of the Ministry of National Service this very serious subject, for never was there a time when *mens sana in corpore sano* was more urgently necessary in the male adolescent than the present.—I am, etc.,

Enfield, May 4th.

HOWARD DISTIN, M.B.

Obituary.

DR. LÉON REVILLIOD, formerly professor of clinical medicine in the University of Geneva, died on March 7th at the age of 82. He was directly descended from Dr. Jean Revilliod (1582-1645), who married Louise Bonet, a sister of Theophilus Bonet, author of the *Sepulchretum*, the first work on morbid anatomy. Léon was born near Geneva in 1835, and was educated at the Academy of that city and afterwards in Paris, where, after serving as interne, he took his doctor's degree in 1865. In 1866 he was appointed assistant physician to the Cantonal Hospital of Geneva, becoming senior physician in 1871. In 1876, when the Faculty of Medicine was established, he was invited to occupy the chair of clinical medicine. In 1899 he resigned his professorship and his hospital appointment. He wrote largely on tuberculosis, and among other subjects dealt with by him were thyroidism, affections of the medulla, fixation abscesses, and the treatment of asthma by antidiphtheria serum. Revilliod was president of the Medical Society of Geneva in 1875 and again in 1902, and was elected a corresponding member of the Paris Académie de Médecine in 1894. He took an active part in the international medical congresses held at Geneva (1877), Amsterdam (1879), London (1881), and Rome (1894), being an honorary president of several of these assemblies.

DR. THOMAS DAVISON CROTHERS, the well-known American authority on inebriety, died at Hartford, Connecticut, of pneumonia, on January 13th. He was born at West Charlton, New York, in 1842, and took his degree at the Albany Medical College in 1865. He was appointed assistant professor of the practice of medicine in the college in 1870, and in 1875 became assistant professor at the New York Inebriate Asylum at Binghamton. In 1878 he was appointed superintendent of the Walnut Hill Asylum, Hartford, and when that institution became the Walnut Lodge Hospital in 1880 he was chosen president and superintendent, and retained that position till his death. He was editor of the *Journal of Inebriety* from 1876, and secretary of the Association for the Study and Care of Inebriates. Dr. Crothers's whole professional life was devoted to the treatment of inebriety and the drug habit. He was the author of *The Diseases of Inebriety* (1893), *Drug Habits and Their Treatment* (1901), *Morphinism and other Drug Diseases* (1902), *Clinical Study of Inebriety* (1911), besides numerous contributions to medical journals.

The death has occurred, at the age of 58, of Dr. WILLIAM HENRY FORDHAM, who had practised in Sheffield for more than thirty years. After studying medicine at

Edinburgh and the Leeds Medical School, he obtained the diplomas L.R.C.P. and L.R.C.S. in 1886. Dr. Fordham had long taken a prominent part in the public affairs of Sheffield, serving for nine years on the city council and doing good work on numerous committees and other local bodies. He was deputy chairman of the Health Committee, in the work of which his professional knowledge and sound common sense were especially valuable. Every form of public endeavour found in him a keen supporter, and last year he was appointed a justice of the peace for the city. For the past year or two his health had been failing, but he was not seriously ill until a week before his death.

MANY members of the profession will have heard with deep regret of the death, on April 24th of Mr. MUNRO SCOTT, who was warden of the Medical College of the London Hospital from 1880 to 1910. During the whole of this period he served the institution with the greatest zeal and devotion, and was rewarded by seeing it steadily advance in influence and prosperity. Conservative in his outlook, he relied on the maintenance of a high standard on old traditional lines. A man of great perspicacity, wide experience, and sound judgement, a man, too, of warm heart and genial humour, he will be long and honourably remembered by all who knew him.

PROFESSOR BERNHARD KRÖNIG has died at the age of 53. He did much to make Freiburg a teaching centre for gynaecology, and though his name has lately been much associated with "painless" labour, his chief work was concerned with the use of ray treatment in gynaecology.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation, held on May 2nd, the degree of M.D. was conferred, in absence, upon E. Burstal.

UNIVERSITY OF CAMBRIDGE.

THE election of a representative of the university upon the General Medical Council will take place on May 14th. Professor Sir T. Clifford Allbutt, the representative since 1908, does not seek re-election.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

SURGERY.—†D. A. Dyer, †C. W. Hayward, †S. C. Ho, †G. L. Mitchell.
 MEDICINE.—†N. Cheua, †A. E. Collie, †M. Girgis, †S. V. Goldhurst.
 FORENSIC MEDICINE.—N. Cheua, M. Girgis, S. V. Goldhurst, H. A. Hughes, T. A. Jordan, C. W. Lakin.
 MIDWIFERY.—H. Carter, G. F. Smith, W. J. Wood.

* Section I. † Section II.

The diploma of the society has been granted to Messrs. C. W. Hayward, S. C. Ho, and G. L. Mitchell.

The Services.

INDIAN MEDICAL SERVICE.

TEMPORARY COMMISSIONS.

THE India Office is prepared to receive applications for temporary commissions in the Indian Medical Service to medical men having a knowledge of Indian languages and customs. Full particulars can be obtained from the Secretary, Military Department, India Office, S.W.1. The pay will be at the rate of 24s. a day when serving with an expeditionary force unless the applicant is liable to serve under the Military Service Acts, when it will be at the rates admissible for permanent officers of the Indian Medical Service. An outfit allowance of £30 will be issued. The applicant must be prepared to serve for the duration of the war. A gratuity will be awardable, after the termination by Government of a period of satisfactory service with an expeditionary force overseas. Wound and family pensions and gratuities will be granted under conditions and on the scales applicable to the Indian Medical Service.

ROYAL ARMY MEDICAL CORPS FUND.

THE annual general meeting of the R.A.M.C. Fund (Regular Army) will be held in the library of the Royal Army Medical College, Grosvenor Road, S.W., at 2.30 p.m., on Monday, June 10th, under the presidency of the Director-General. The annual general meeting of the R.A.M.C. Benevolent Society

Regular Army) will take place immediately afterwards. Officers desiring information regarding these funds are requested to communicate beforehand with the secretary, Lieut.-Colonel E. M. Wilson, 124, Victoria Street, S.W.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS. THE usual quarterly committee meeting was held at 11, Chandos Street, Cavendish Square, W., on April 25th, 1918, when grants were made to the orphans of three commissioned officers of the Auxiliary R.A.M.C. and to the widows of three of the rank and file of the Auxiliary Branch of the R.A.M.C. Applications for grants and subscriptions to the funds should be addressed to the honorary secretary, 11, Chandos Street, Cavendish Square, W.1.

Medical News.

THE inter-allied conference on the after-care of discharged sailors and soldiers will be opened at the Central Hall, Westminster, on Whit Monday, May 20th, at 11.30 a.m., by the Duke of Connaught. The King and Queen will visit the exhibition arranged in connexion with the conference at 12.30 on the same day. The conference and exhibition will close on Saturday, May 25th.

ANOTHER discussion at the Royal Society of Medicine on the future of the medical profession under a Ministry of Health will be opened by Sir William Osler on Wednesday, May 29th, at 5 p.m.

DR. R. HOWDEN, professor of anatomy in the Faculty of Medicine, Newcastle-on-Tyne, has been appointed to represent the University of Durham on the General Medical Council.

DR. JAMESON B. HURRY has presented to the Town Council of Reading an historical picture by Mr. Harry Morley, A.R.C.A., representing the martyrdom of Hugh Faringdon, last Abbot of Reading.

THE Disabled Soldiers' Aid Committee (40, Ebury Street, London, S.W.) asks for disused periodicals, to be made into war envelopes by disabled soldiers, whereby they are able to earn as much as £1 a week.

ON the initiative of Professor Gradenigo stations of psycho-physiological research on the effects of aviation have lately been founded at Turin and Naples. They are chiefly intended for the examination of candidates for service as air pilots.

A CONFERENCE on maternity nursing will be held in the Board Room of the Metropolitan Asylums Board (Embankment, Blackfriars Bridge) on June 4th. Sir William J. Collins, M.P., who will preside, will open a discussion at 5 p.m. on maternity nursing in relation to the district nursing services of London.

THE first of a course of lectures and demonstrations on ambulance work and first aid will be given at the College of Ambulance, Vere Street, Cavendish Square, W., on Thursday next, at 4.30, by Sir James Cantlie, K.B.E., who will deal with aid to the agricultural worker. Other lectures will be given at the same hour and place on Thursdays during May, June, and July. Particulars can be obtained from the secretary.

DURING the annual meeting of the South-Eastern Union of Scientific Societies, which is to take place in London at the end of this month in the rooms of the Linnean Society (Burlington House, Piccadilly, W.), a discussion on mosquitos in England will be opened by Colonel Sir Ronald Ross, K.C.B., F.R.S. This discussion will be held at 8 p.m. on Thursday, May 30th, in the theatre of the Civil Service Commission, Burlington Gardens, Piccadilly, W., and will be open to all interested in the subject.

AT a meeting of the East Sussex Medico-Chirurgical Society held at the East Sussex Hospital on April 26th Dr. Overend gave an x-ray demonstration of certain diseases of the chest by means of lantern slides. After illustrations of the normal chest slides were shown of hilar and peritracheal phthisis in various stages; of interlobar tubercle (discrete and confluent) and its subsequent development, either into ordinary disseminated peribronchial phthisis, or into a slow, advancing fibro-caseous form, with the formation of cavities in the interlobar area, which are often silent to the stethoscope. In one example the interlobar opacity was grafted on pneumoconiosis. Radio-slides were also exhibited showing disseminated peribronchial tubercle, unilateral and bilateral, active and progressive, stationary and arrested, with the production of cavities; chronic indurated phthisis, and unilateral pure fibroid lung; asthma and emphysema; commencing and resolving pneumonia; Hodgkin's disease and mediastinal sarcoma affecting the paratracheal glands, before and after x-ray treatment; bronchiectasis and subphrenic abscess.

THE United States Secretaries of State of War and Navy have authorized the organization of a committee in Washington, with branch committees in London and Paris, for the collection, classification, and dissemination of scientific, technical, and industrial research information, with special reference to war problems, and the interchange of such information between the Allies in Europe and the United States. The British and French committees are to establish contact with all important research laboratories and agencies, governmental and private. They will prepare reports on the results obtained; maintain continuous contact with the work of military and naval attachés; serve as auxiliaries in the collection, analysis, and compilation of information, and as centres of distribution to the American Expeditionary Forces in France and to the American naval forces in European waters of scientific and technical information originating in the United States and to the Allies in Europe. The headquarters of the Committee in Washington are in the offices of the National Research Council, 1023, Sixteenth Street. The branch committees are located at the American Embassies in London and Paris.

Letters, Notes, and Answers.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 423, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atitology, Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 423, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

HAY FEVER.

DR. LIONEL JAMES PICTON writes in response to our request for suggestions for the local treatment of hay fever: I have found that the unguentum acidi salicylici introduced several times a day into the nostrils—either with the little finger or the butt end of a wax match or wax taper—is of value.

UNIVERSITY REPRESENTATION IN PARLIAMENT.

J. C. writes: Dr. Fothergill's letter in the BRITISH MEDICAL JOURNAL of April 20th contains the following: "... who knows his subject and *who* we can support." The letter in the JOURNAL of May 4th signed by Sir W. M. Abbot Anderson and Herbert G. Williams contains the following: "These are presumably the official bodies *whom* he suggests should wake up." Alas for the preliminary education which is displayed in these letters.

INVALID RATIONS.

DR. A. KINSEY-MORGAN (Bournemouth) writes with reference to Dr. E. I. Spriggs's article (p. 505): Differentiation is not always made between constitutional and alimentary diabetes; thus with a mistaken diagnosis the patient is burdened with an unsuitable diet for his requirements; such a case has quite recently come under my observation. "Extra rations," as Dr. Spriggs points out, are only suitable for "subjects of persistent glycosuria who are in need of special diet." In tuberculous cases it is imperative that a generous diet of protein and fat should be allowed; nutrition is thus maintained, and the arrest of the disease is a manhood gain from the public point of view. Dr. Spriggs's concluding remarks on "restricted tastes" are words of wisdom which should appeal to all of us as a great help out of many of our daily difficulties.

TWO CASES OF PTOSIS (? BOTULISM).

DR. JOHN W. DUNCAN (Hockley, Birmingham) sends us notes of two cases he has seen within the last fortnight which may be instances of botulism. (1) A married woman, several months pregnant, who had been ill a few days, was, when first seen, sitting by the fireside with both eyes closed. She was dull, but spoke when addressed and could raise the eyelids, the right more than the left. She had herpes on the upper lip. She was admitted to hospital next day. (2) A man aged 55, first seen on April 19th, had been ill for some time with drowsiness, closed eyes, and twitching fingers. On the previous night he had delusions. He was constipated, and the temperature was raised—on May 4th it was 103°; since May 3rd he had been confined to bed, comatose, speechless, and taking no food. The eyelids are persistently closed, and he does not respond when spoken to. The right side of the face is smooth, the left drawn, showing a deep line. The hands twitch; the plantar reflexes are present. The bowels

have been opened after castor oil. The only point in his history bearing on his illness was that he had eaten pig's pudding a fortnight before being taken ill.

TREATMENT OF MENINGITIS.

MRS. Fysh, M.B.Lond. (Dryhurst, Tonbridge), writes: In reply to Captain Cade (April 13th, p. 444) I would recommend the iodine treatment, which must be carried out carefully in every detail, for example, the iodine tincture being applied all over the head and not merely "to the shaven crown," for meningitis in cases of the acute suppurative variety either alone or complicating an acute fever such as pneumonia or enteric. I have only tried it in one case of the tuberculous variety; it was unsuccessful, but the child (a Jewess of 10 years) came under my care late in the second week of her illness. Of the four other cases mentioned in my previous letter, one, a woman, died, and pus was found in the meninges in all parts; it was white, and in places inspissated, as if beginning to undergo absorption. Dr. Castellani reported the presence of a diplococcus in this case. The diagnosis of the other three was made on clinical grounds only; they were all very acute and apparently hopeless young children suffering from the characteristic symptoms, one having passed the convulsive stage and being in deep coma when he began at last to respond to treatment. This is a kind of meningitis which so far I have not seen in England, but which occurs with some frequency in Ceylon.

GLYCERIN IN THE TREATMENT OF WOUNDS.

DR. A. OGIER WARD (London, E.C.) writes with reference to Mr. A. E. Morison's article (March 23rd) on the virtues of magnesium sulphate for wounds: I find that the recipe contains 1½ lb. magnes. sulph. and 11 oz. glycerinum ac. carbol. (1 to 10). Why use the magnesium sulphate? Is it not true that the key to all antiseptic treatment should be recognized to be osmosis? And is not glycerin the simplest and most ideal substance for its promotion?

DO MOVING PICTURES INJURE THE EYES?

IN a communication to *The Annals of Ophthalmology* last year Dr. Bahn of New Orleans comes to the following conclusions: (1) Moving pictures, under favourable conditions, do not cause as much fatigue as the same period of concentrated reading. (2) Most persons who complain that the pictures cause ocular discomfort have some defect of the eye. (3) Moving pictures act as a test of distant vision endurance. A person with no ocular defect should be able to enjoy at least four sittings, of one and a half hours each, a week with no discomfort. (4) Under unfavourable conditions the pictures produce ocular fatigue. (5) A review of the literature up to date records no permanent harm to the eyes from the cinema.

AN OLD MILITARY MEDICAL PHARMACOPOEIA.

DR. OLDERIGO GRANDINI gives in *La Medicina Pratica* an account of a *Pharmacopoeia Austriaco-Castrensis*, printed at Vienna in 1795. It is a list of the remedies then considered most useful for soldiers on campaign. It includes vulneraries (Hoffmann's liquor and the theriaca); extracts of aconite, anodynes, taraxacum, and bark; liquorice plasters (simple, compound, and blistering); sublimate and other mercurials; anodyne, mercurial, and purgative pills; Dover's powder; resins of guaiacum and julep; confections of elder, juniper, and prune; Glauber's salts, tartar emetic and other forms of tartar; oils of aniseed, juniper berry, peppermint, turpentine, and laurel berry; antimony in various forms; vinegars (litharge and squills); mercurial, "nerve," and other ointments, one being for scab. Fifty-nine formulae are given for the use of these substances in military hospitals.

THE BEGINNING OF CLINICAL TEACHING.

ANDREA FERRANNINI, writing in the *Riforma Medica*, claims for Italy priority in the foundation of scientific academies. The Accademia Cosentina was founded by Parrasio at Cosenza in 1550; the Accademia dei Segreti, a leading member of which was Giovanni Battista della Porta, discoverer of the camera obscura and founder of the science of physiognomics a century before Lavater, at Naples in 1600; the Accademia dei Lincei at Rome, by Prince Cesi, in 1603; the Accademia del Cimento, by pupils of Galileo, under the patronage of Prince Leopold of Tuscany, in 1657. The Royal Society of London was founded in 1660, and the Paris Académie des Sciences in 1666. The first Academy of Medicine in Europe was founded at Palermo in 1623 as an annexe to the School of Anatomy. Ferrannini also claims precedence for Italy in the foundation of university chairs of medicine. He says that the first anatomical amphitheatre was established at Padua in 1490 through the efforts of Alessandro Benvenuto, and the first chair of clinical medicine at Padua by Giovanni Battista Da Monte in the hospital of St. Francis in 1543. Instruction at the bedside had, however, been given in ancient Rome, as we know from Martial's epigram about Symmachus; in the Nestorian school at Edessa in the fifth century, in the Arabic schools, and also by some mediaeval teachers, such as Lanfranc. Withington, in his *Medical History from the Earliest Times* (p. 312), says that although the system had been revived at Padua for a short period during the Renaissance, clinical teaching in the modern sense had its origin in the "little infirmary at

Leyden with its twelve beds." Francis de la Boe (Sylvius, the discoverer of the fissure in the brain which bears his name), writing in 1664, says: "I have led my pupils by the hand to medical practice, using a method unknown at Leyden, or perhaps elsewhere, that is taking them daily to visit the sick at the public hospital."

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

Subscriptions to the Second Appeal.

The following subscriptions and donations to the Fund have been received during the week ending May 4th:

	£	s.	d.		£	s.	d.		
Dr. John Fletcher	...	1	1	0	Dr. E. C. Prichard	...	3	3	0
Dr. W. O. Magoris	...	2	2	0	Lieutenant John Ritchie.	...			
Dr. Hodgson Moore	...	1	1	0	R.A.M.C.	...	1	1	0
Dr. J. B. Cumming	...	2	2	0	Dr. T. Ridley Bailey	...	1	1	0
Dr. J. A. Alston	...	1	0	0	Dr. Percy Rowland	...	0	10	6
Surgeon James M. Harrison, R.N.	...	0	10	5	Sir Alfred Pearce Gould	...	6	0	0

Monthly Subscriptions.

Surgeon P. G. S. Davis, R.N.	...	0	10	0	Mr. E. Spencer Evans	...	0	10	0
Sir Alfred Pearce Gould	...	5	0	0	Dr. Herbert Caiger	...	0	10	5

Subscriptions to the Fund should be sent to the Treasurer, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyd's Bank, Limited.

THE COMMEMORATIVE MEDAL IN THE SERVICE OF GERMANY.

THE industry of German propagandists in keeping up warlike enthusiasm in their own homes and in attempting to impress neutrals is curiously shown in the issue of war medals, of which at least 580 have found their way to other lands; selections can be studied in the Victoria and Albert Museum, South Kensington, and in the War Exhibition at Burlington House. With the light touch of a velvet-covered hand, Mr. G. F. Hill, Keeper of the Department of Coins and Medals, British Museum, has described, in a pamphlet with the title at the head of this note (Longmans, 6d.), the various kinds, and criticizes their bearings—the patriotic impressions of the reigning house, including that of the Crown Prince, which, if, as is reported, they be accurate, have surely rendered the caricaturist's skill unnecessary; the hero-worshipping reproductions of von Hindenburg, of von Tirpitz—nothing if not genial—of von Kluck wistfully gazing at the distant fortifications of Paris; the "victory pennies" of the bombardment of Scarborough and Hartlepool and of Zeppelin attacks on the London docks; and the medals for satiric purposes, such as the notorious *Lusitania* production "flagellating the levity of mind of the Cunard line," and that of the landing of the Indians at Marseilles. While exposing the want of humour and the bad taste obvious in many instances, Mr. Hill refers to the pleasing conception of Götz's memorial medal of Admiral von Spee and his two sons with the German Eagle flying over a waste of waters to lay a laurel branch on their ocean grave. This is shown in one of the seventeen illustrations. That museums devoted to the ethnology of primitive races should preserve specimens of these German war medals for the future student is a proper provision.

A GAS GANGRENE RHYME.

H. M. E. sends us the following metrical "tip," which, though rather absolute, has, he says, proved helpful to a casualty clearing station in France:

When a compound fracture's seen, bobbly pus denotes gangrene.
If the skin is grey and mottled and the circulation's throttled,
Resonance upon percussion does away with all discussion.
Amputate by night or day; death ensues if there's delay.

THE appointment of certifying factory surgeon for Newbury (Berks) is vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

				£	s.	d.
Seven lines and under	0	6	0
Each additional line	0	0	9
Whole single column	4	0	0
Whole page	12	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

INTRAVENOUS INJECTION IN WOUND SHOCK.

ABSTRACT OF THE OLIVER-SHARPEY LECTURES DELIVERED
BEFORE THE ROYAL COLLEGE OF PHYSICIANS ON
APRIL 30TH AND MAY 2ND, 1918.

BY

W. M. BAYLISS, D.Sc., F.R.S.,

PROFESSOR OF GENERAL PHYSIOLOGY, UNIVERSITY COLLEGE,
LONDON.

THE founder of these lectures was never tired of insisting on the importance of clinical measurements of the blood pressure, and himself devoted much valuable work to the design of appropriate methods of performing such estimations, as well as to methods of determining the haemoglobin percentage contained in the blood. It is therefore not inappropriate that I should ask your attention to the part played by changes in the blood pressure in wound shock, and to the importance of the supply of oxygen to the tissues.

The name "wound shock" was given by Captain Cowell to that state, resulting from injury, which shows itself as a general depression of vital activities, and may end in death if not combated. The names "surgical" and "traumatic" shock have also been used, but "wound" shock seems to be, on the whole, preferable.

Two stages are usually met with in the development of this state, which stages have been called "primary" and "secondary" shock. Either of these may be absent, and the former may pass insensibly into the latter.

DEFINITION.

Primary shock occurs immediately on receipt of the wound, and is in many ways similar to an exaggerated fainting. The collapse and fall of blood pressure is of benefit in that it tends to lessen haemorrhage. If the patient is kept warm and quiet during transit to the casualty clearing station the blood pressure may return to normal. On the other hand, after partial recovery, secondary shock may present itself with renewed low blood pressure and the various results of this condition. The low blood pressure and its consequences are the most general and obvious signs of the state of secondary shock, and it is with these that we are concerned in this place. When I refer to wound shock, it is to be understood that it is the secondary state which is under consideration, as being that requiring treatment.

NATURE OF WOUND SHOCK.

What is the actual nature of wound shock, and especially what is the immediate cause of the low blood pressure apart from haemorrhage, is still obscure.

Conditions which can be Excluded.

It will clear the way, however, if I mention briefly some suggestions that can be at once put on one side.

Acapnia (diminished carbon dioxide in the blood)—because the respiration is not of such a kind as to result in excessive removal of carbon dioxide.

Adrenal exhaustion—because adrenaline is present in excess when shock comes on.

Exhaustion of nerve centres—because reflexes are not diminished to any important degree except when the blood pressure has remained at a low level sufficiently long to paralyse the centres from want of oxygen.

Inefficient action of the heart—because when the arterioles are constricted by a dose of adrenaline the heart is quite able to raise the blood pressure to a high level.

Paralysis of arterioles or veins, especially of the abdominal area—because direct observation in the course of abdominal operations fails to show any abnormal distension.

The Hypothesis of "Exaemia."

The view which finds most favour is that of an accumulation and stasis of blood in capillary areas, so that it is removed from currency as effectively as if lost to the exterior. The name "exaemia" has been proposed by Major Cannon on this hypothesis. Whether there has been haemorrhage or not, then, there is a deficiency of blood in circulation, and the natural result of this is a low

arterial pressure and a failure to supply the tissues with their normal requirements in oxygen.

But why is a low blood pressure the cause of such serious results as to need correction as soon as possible? It will be clear that the due supply of blood to the organs of the body depends upon an adequate pressure. The blood conveys oxygen and removes carbon dioxide and other waste products. Gesell has shown that the blood flow through an organ is reduced more by a fall from a high pressure to a moderate one than by a further fall of the same extent, and that, as the pressure falls, the blood supply is reduced to a greater proportion than the pressure itself. I have been able to confirm this statement, and the practical conclusion to be drawn is that even a moderate fall of blood pressure is not to be looked upon as of little consequence.

Effects of Insufficient Blood Supply Owing to Low Pressure.

The pathological changes which take place in cells when insufficiently supplied with blood are well known. I may mention the suppression of renal secretion, the failure of cardiac contraction below about 90 mm. Hg (Markwalder and Starling), and the changes in nerve cells. Recovery takes place if the pressure is restored without too long a delay. In cats I found that the vasomotor centre loses reflex excitability after one to two hours of an arterial pressure of 60 mm. The respiratory centre fails earlier (Pike and Stewart, Pilcher and Sollman).

A good blood supply is also necessary because various other injurious influences, such as cold, injury to muscles, asphyxia, anaesthetics, acid production, temporary obstruction of circulation to a large part of the body, may not be great enough to have serious consequences, each by itself alone, but becomes so when combined with a small loss of blood, itself also innocuous alone. Gas gangrene is stated to be held in check by a good circulation of blood. Finally, renal secretion is directly dependent on the arterial pressure, so that the elimination of acid and toxic products in the urine is retarded by a low pressure. Experimentally, one finds that the other symptoms of shock disappear when the blood pressure is raised. For example, the rapid shallow respiration after muscle injury is restored to normal when the blood pressure is raised by injection of gum solution.

It appears, indeed, that what we call wound shock is the result of a more or less complex combination of various deleterious factors, not always the same, but always exaggerated by haemorrhage, which is rarely absent, though sometimes not great.

Since the introduction of the Riva-Rocci instrument and its modifications, of which the "Tycos" is very easy to use and keep in order, the measurement of the blood pressure has become a simple matter and ought to become a routine practice.

MEANS TO RAISE BLOOD PRESSURE IN WOUND SHOCK.

What means shall be used, then, to raise the blood pressure in shock? I would point out, to begin with, that a high blood pressure is not our object for its own sake. We wish to increase the blood supply and oxygen supply to the tissues, especially to vital organs such as the nerve centres and the heart. For this reason the use of vaso-constrictor drugs is to be deprecated. Apart from their transitory effect, the result is actually a lessened blood supply to the tissues, because the rise of blood pressure is obtained by narrowing the arterioles which convey the blood. The correct way is to increase the volume of blood in circulation, which involves a raised arterial pressure without decrease of peripheral blood flow.

It is natural to assume that transfusion of blood itself is the best way to do this. I do not propose to discuss this matter at length. A detailed memorandum will shortly be published by the Shock Committee of the Medical Research Committee. Donors are not always available in sufficient number, however, and it is a difficult matter to keep on hand preserved blood or suspensions of corpuscles in sufficient quantity to meet emergencies. A substitute, if efficient, is highly desirable, especially if of such a kind as to be available in unlimited amounts. I may anticipate a little here to remark that, somewhat to my surprise, blood has not shown itself, experimentally, to be so far superior to certain artificial solutions as would have been

expected. If a given case failed to respond to gum, blood was also ineffective. It is probable that, under ordinary conditions, we possess a reserve of haemoglobin, so that the tissues are sufficiently supplied with oxygen by a diluted blood, so long as the body is at rest. Captain Bazett has found cases doing well with a very low haemoglobin value. Another experimental fact seems of some significance: a dilute blood is more effective under a high pressure than a normal blood under a low pressure. This is no doubt connected with the fact above mentioned, that a high pressure is relatively more effective than a low pressure, a fall of one-third means a fall in blood supply by two-thirds or more.

Various Fluids Proposed and Used.

Ringer's solution, although naturally one of the first to be tried, has been found to be useless, both experimentally and in actual practice. It leaves the vessels in the course of half an hour or so, while the blood pressure returns to its former level or even lower. Why is this? Such saline solutions have two obvious defects when compared with blood. These are (1) a low viscosity, so that a given volume is much less effective than its equivalent in blood, even in its immediate effect, and (2) the absence of a colloid with an osmotic pressure. The value of the latter is somewhat difficult to explain shortly. Since the blood vessels are freely permeable to water and salts, while impermeable to colloids, the osmotic pressure of the latter is active and prevents the escape of fluid to the tissues by its attraction for water. Thus the colloids of the blood must not be diminished in strength, for otherwise they do not keep the water from being filtered out in excessive amount by the arterial pressure.

Hypertonic Saline.—This has been used with the object of preventing this escape of fluid by means of the osmotic pressure of the salt. But it will do this only so long as the salt content in the blood remains higher than that of the tissue fluid. Since salts diffuse through the walls of the blood vessels at a great rate, their concentration rapidly becomes equal on both sides, and then the conditions are the same as with Ringer's solution. Experimentally I have found that 2 per cent. sodium chloride is very little, if any, superior to isotonic saline for the purpose in view. It may be mentioned that its value in cholera may be due to other causes, which do not concern us here. Hypertonic saline produces oedema of a perfused organ just as isotonic saline does. Moreover, the injection of hypertonic solutions of any kind requires care; I have seen unpleasant symptoms, such as gasping respiration and slowing of the heart, in cats.

Addition of calcium has been recommended for two reasons. It acts as a vaso-constrictor. But this is very transitory, and we have seen that it is undesirable. It has been stated to decrease the permeability of the blood vessels, and so prevent oedema and transudation in various situations. I have, however, been unable to detect any difference between the rate at which Ringer's solution with and without excess of calcium leaves the circulation, and Cushman has tested the effect on transudations without obtaining any effect.

Acidosis.

Alkaline solutions (sodium bicarbonate) are advocated on the ground that "acidosis" is found to be present in wound shock (Cannon). A brief consideration of this matter is necessary. The blood, of course, never becomes really acid. What happens is that a part of its normal bicarbonate content becomes neutralized by combination with some fixed acid (lactic, etc.) produced in the tissues on account of defective oxygen supply. The point is, does this involve an increase of the hydrogen ion concentration? Is there any real increase in acidity? Some observers have thought such a change to be the essential cause of shock. We may note that the various results described as produced by acidosis are those due to rise in the hydrogen ion concentration. In experiments made to test the question, I have found that as much as one-third to one-half of the bicarbonate can be combined with fixed acid without the production of any increase in the hydrogen ion concentration of the blood.

What is the explanation of this? The first effect of the introduction of acid into the blood is to drive off carbon dioxide from a part of the bicarbonate, thus temporarily

raising the hydrogen ion by excess of carbonic acid. But as soon as such blood reaches the respiratory centre, hyperpnoea is caused and the excess carbon dioxide is rapidly removed by the increased ventilation of the lungs. Normally, as Haldane and Priestley have shown, the respiratory centre is extraordinarily sensitive to hydrogen ions and responds by a vigorous discharge.

But, it will be said, suppose the centre is less sensitive, owing to a dose of morphine, for example. Can the "acidity" of the blood rise to a serious extent? I have also tested this possibility. As Lawrence Henderson has shown, as long as any bicarbonate remains there can only be a small rise in the hydrogen ion concentration of the blood, or any similar solution, since the carbon dioxide for the most part cannot remain in solution. The actual change in the blood in my experiments was not greater than the difference between the values of concentrations of hydrogen ion between 1.58×10^{-7} and 1.26×10^{-7} normal. This is extremely small and would be produced by the addition of 0.01 gram of lactic acid to about 10,000 litres of water. To change the more acid blood into normal blood would require merely the reduction of the alveolar content in carbon dioxide to one-half its normal value, a change easily effected by respiration. Henderson and Haggard point out that to maintain the hydrogen ion constant when the Van Slyke value falls from 63 to 42, a marked "acidosis," requires only 50 per cent. more ventilation of the lungs, and that people living at high altitudes have a "normal" hydrogen ion concentration although their carbon dioxide level is very different from that at ordinary barometric pressure.

We may next consider briefly whether the physiological results ascribed to acidosis could be produced by so small a rise in hydrogen ion concentration as may occur.

Stimulation of Nerve Centres.—With the exception of the respiratory centre, the bulbar centres are not easily stimulated by acid. We know that the vasomotor centre is stimulated in asphyxia by the carbon dioxide in the blood, but Mathison has shown that a fairly strong acid injection is required to do this.

The Heart.—Patterson showed that the heart is affected deleteriously by respiration of carbon dioxide of 5 per cent., but not below this value. This is equivalent to neutralizing more than two-thirds of the bicarbonate by acid, supposing that the respiratory centre were inactive. Moreover, the effect of acid is antagonized by very small amounts of adrenaline.

The Arterioles.—Very weak acid (1 in 10,000) causes dilatation. But the hydrogen ion concentration of Ringer's solution is raised by this addition to more than 1,000 times that possible in acidosis.

Capillary blood vessels, Severini stated, were dilated by carbon dioxide, but Roy and Graham Brown failed to confirm the statement. Dale and Richards have brought forward indirect evidence that acid has not this effect.

Transport of Oxygen.—As Barcroft showed the presence of acid in the blood, while it does not much affect the amount taken up by haemoglobin at the alveolar tension of oxygen, reduces the amount held by it at the oxygen tension in the tissues. Consideration will show that this is really an advantage, since the blood arrives at the tissues with practically as much oxygen as normally, while it leaves the tissues with less. The state of acidosis provides the tissues with an increased supply of oxygen.

Viscosity of Blood.—Although statements have been made that acid increases this property, I have been unable to detect any change, even on saturation with carbon dioxide.

Red corpuscles, Hamburger showed, swell in the presence of carbon dioxide. That this does not produce a rise in viscosity is possibly to be explained by the fact that they do not increase in diameter, but become more spherical.

Swelling of Colloids.—Martin Fischer has advocated a series of theories of oedema and nephritis, etc., on the basis of the swelling of colloids and cells by acid. But his experiments show that a concentration of lactic acid greater than N/80 is necessary to affect fibrin or muscle. This has a hydrogen ion concentration more than 10,000 times that possible in blood.

Oxidation Processes.—Some oxidation processes are depressed by acid, but others are not, and the increase found experimentally in soa-urbin eggs was produced by comparatively strong alkali. Lactic acid is rapidly oxidized

in muscle in acid medium, provided that oxygen is freely supplied.

In *diabetes* there is a low bicarbonate reserve, but the blood pressure is not low, while the state could scarcely be called one of shock. Poulton has shown that there is no increase in the hydrogen ion concentration in coma.

Experimental Injection of Acid.—Sometimes, especially in unhealthy animals, the introduction of acid leads to progressive fall of blood pressure to a shock level. But, on the other hand, large quantities may be injected without result, as Dale and Richards have shown. I find no difference between the effects of acid and neutral phosphates in equal amounts.

Conclusions as to Acidosis.

On the whole, I am compelled to conclude that "acidosis" is not in itself a serious factor in shock, and that alkaline injections are not called for. The existence of a decreased bicarbonate content is, however, a sign of defective oxygen supply. In various forms of experimental shock I have found the injection of bicarbonate solutions of small and temporary value only. What effect was produced might have been equally well due to the volume of fluid introduced. If other reasons are thought to require the use of alkali, it is best given by stomach or rectum. The effective way of treating the production of acid in the tissues is by increasing their supply of oxygen from the blood. This suggests that a slight increase of acidity may really be of benefit, since it stimulates the respiratory centre to increased ventilation of the lungs.

Solutions of salts in general are merely of temporary value, and liable to be followed by a greater fall of blood pressure.

REASONS FOR USING A COLLOID: GUM ARABIC.

A colloid must be added to remedy the defects of such solutions. What substances are available and possible for the purpose?

Since such a colloid must possess an osmotic pressure, starch and agar can be excluded at once. Dextrin is deficient in viscosity. Proteins are inadmissible on account of anaphylaxis. They have also an injurious effect on the kidney. We are left with gelatin and gum arabic, both of which satisfy requirements both as to viscosity and osmotic pressure. There are objections to gelatin on account of its liability to contain tetanus spores. But the more serious objection is its liability to cause intravascular clotting, as found by Dale and Richards. Fortunately, gum has none of these defects. A solution of 6 per cent. strength has been found, both in the case of wounded men and in lower animals, to maintain the blood pressure indefinitely. It does not leave the blood vessels. Gum is quite innocuous, even in a volume equal to one-half of the total blood volume, or an injection of more than a litre and a half in man. It produces no haemolysis nor agglutination in man and does not increase the viscosity of the blood. Since it contains no protein, anaphylaxis in case of a later injection would not be expected, and, tested on guinea-pigs, was found not to occur.

Although gum seems rather a strange substance to introduce into the blood, it is chemically a very inert substance and is not really foreign to animal metabolism. It consists of derivatives of galactose and of arabinose. Galactose is a natural sugar present in milk. Arabinose appears in the urine in pentosuria and appears to arise from galactose by removal of carbon dioxide (Neuberg).

Since commercial products contain small amounts of calcium and potassium salts, there is no need to add them. All that is necessary is the addition of 0.9 per cent. of sodium chloride, and tap water may be used. The solution must be filtered through flannel or other convenient medium and then sterilized. A strength of 6 per cent. is probably the best for routine use, and arrangements are made for its supply through the usual mechanism of the Army Medical Department. In practice, even 3 per cent. has been found greatly superior to saline solutions, but it is clear that its osmotic pressure is not the optimal one.

The value of gum infusions is, naturally, most striking and rapid after haemorrhage. But practical experience, as shown, amongst others, in the cases reported by Captains Cowell and Drummond and Taylor, has demonstrated its utility in various other forms of shock. It is not to be expected to be of avail when the bulbar centres have

permanently lost their excitability; but even blood is useless in such cases. Hesitation might be felt in transfusing blood in a case apparently hopeless, and one advantage of gum is that no restriction in its use need be felt. A case is reported by Captain Cowell, pulseless and moribund on arrival at the casualty clearing station, restored permanently by gum. The dangers of prolonged low blood pressure justify the contention of Colonel Fiaschi and Captain Bullock, who insist on the importance of early intravenous injection, as soon as possible after the injury. There is, of course, some risk of increasing haemorrhage. Drummond and Taylor advocate the use of the tourniquet in the case of wounds of limbs. If there is internal bleeding, it may unfortunately be necessary to defer intravenous injection until operation is commenced.

Experiments with Gum Solution.

On account of the fact that gum showed itself to be useful in wound shock generally, I have made some experiments on cats in order to investigate its effect in states of low blood pressure other than those due to haemorrhage alone. We may remember that there is reason to believe that in all such cases blood is out of currency somewhere and can be replaced by an appropriate solution, allowing recovery to take place in due time.

A shock-like condition may be produced experimentally by prolonged cold, by asphyxia, by local anaemia on reopening the blood current, and sometimes by injection of acid. In all cases the state is much exaggerated by slight haemorrhage and is effectively treated by gum injection. Erlanger and his colleagues have recently found that gum holds fluid in the vessels in all forms of shock with which they worked, that due to exposure and manipulation of the intestines, in addition to that of temporary anaemia of a part of the body. I may remark that, although intestinal trauma is a common mode of inducing experimental "shock," it seems to me that it is rather dissimilar to the actual wound shock met with after shell wounds.

SHOCK IN INJURIES OF MUSCLES.

Probably the most interesting form of experimental shock is that due to crushing of muscles. The experiments were commenced in conjunction with Major Cannon and continued, from another point of view, since his departure. The appearance of the injured muscle reminded us very strikingly of that of muscles in recent shell wounds as we had seen them in France, and the general phenomena are more like those of wound shock than most forms of experimental shock are. General Cuthbert Wallace has called attention to the greater liability to operative shock when large masses of muscle are cut. Compound fractures and multiple wounds are commonly followed by more or less severe shock.

In a typical experiment severe mutilation of the thigh muscles in decerebrate cats, or cats under urethane or ether, results in a primary fall of blood pressure, which may or may not be partially recovered from. This fall is usually followed by a further progressive fall, which can be counteracted by gum with return of the blood pressure permanently to the normal height. The phenomena appear to be due to the absorption of some depressant substance from the injured tissue, since they occur when the spinal cord has been divided in order to exclude nervous reflexes. This substance is either oxidized or eliminated if the blood pressure is high enough. It is not lactic acid, as would naturally be supposed, since the injection of lactic acid during the state of low pressure is rather beneficial than otherwise, and bicarbonate injections are almost useless. Massage of the injured muscles results in a further fall of blood pressure, with dilatation of the intestinal vessels. This fact is of interest in connexion with the great benefit known to follow the immobilization of fractured thighs by the use of the Thomas splint during their transit to the casualty clearing station.

Respiratory Disturbance in Shock.

A remark may be made on the peculiar form of respiration shown in these cases of muscle injury. It has often been noticed that wound shock is associated with a rapid but shallow breathing, occasionally interrupted by a deep sigh. This is also the case in cats, where the rapid return to normal when the blood pressure is raised by gum is

very striking. The cause and nature of the phenomenon require investigation. It may also be seen after haemorrhage, but, so far as my experiments go, a mere fall of blood pressure, as by inhibition of the heart or the injection of a dose of acetyl-choline, does not produce it. It has some significance in connexion with acidosis, because it is quite different from the rapid but deep breathing caused by rise in hydrogen ion concentration. A condition similar to the respiration of shock has been described by Haldane in late stages after gassing, and ascribed to an exaggeration of the Hering-Breuer inhibition of inspiration.

Conditions in which Gum Injections are Valuable.

Some cases treated with gum injections by Fraser and Cowell and by Drummond and Taylor may be briefly mentioned in order to indicate the variety of states in which it may be of service to practise such injections. Severe haemorrhage from abdominal wounds and from arteries; cases in which haemorrhage and shock were not excessive, but in which a dangerous fall of blood pressure followed operation; other cases in which there was severe shock, but only slight haemorrhage, were all treated with success. Some of these were complicated by gas gangrene, and one case of this infection in which there was neither shock nor haemorrhage, but a blood pressure of only 70 mm. Hg, recovered after the blood pressure had been restored by gum.

GENERAL CONCLUSION.

The general practical conclusion to be drawn from the various considerations brought forward is, I think, that the main factor in the successful treatment of wound shock is to ensure an adequate supply of blood—that is, of oxygen—to vital organs, especially to the nerve centres. This is most simply done by intravenous injection of gum solution, which does not appear to be, in most cases, inferior to blood. When very great haemorrhage has occurred, it would seem reasonable that blood transfusion should be preferred.

If the use of sodium bicarbonate is thought necessary, it is best given by stomach or rectum. But it has not yet been demonstrated that the symptoms relieved by bicarbonate would not be more effectively cured by raising the blood pressure. In principle it would seem to be a mistake to reduce the slight increase of acidity in the blood, since this is of value in stimulating the respiratory centre, and there is no evidence that the slight increase of hydrogen ion concentration which is present in some cases of acidosis, but not always, is in any degree harmful in itself.

A Collective Investigation

OF

TEN THOUSAND RECRUITS WITH DOUBTFUL HEART CONDITIONS.

Conducted at the National Hospital for Diseases of the Heart by C. CHAPMAN GIBBES, R. O. MOON, S. RUSSELL WELLS, P. HAMILL, F. W. PRICE, and J. STRICKLAND GOODALL.*

Preliminary Report, compiled by
S. RUSSELL WELLS, M.D., B.Sc.

In February, 1916, by desire of the War Office, the honorary medical staff of the National Hospital for Diseases of the Heart undertook to act as expert referees on all cases of doubtful cardiac conditions referred to them by the various recruiting boards of the metropolitan area.

Methods Employed.

In every case an exhaustive medical history was taken, inquiry was made into subjective symptoms complained of, and the ordinary clinical examination by inspection, palpation, percussion, and auscultation was undertaken. In addition to this the urine of every recruit was examined, the pulse, blood pressure, and the respiration was taken in

the recumbent position before and immediately after a standardized piece of exercise, and again after three minutes' rest in the recumbent position. Each case was electro-cardiographed, and the heart was examined by means of the *x* rays. As the result of these various methods of examination a diagnosis was arrived at, and the medical boards were advised as to the category for service for which, in the opinion of the examining physician, the recruit was fitted, the responsibility for the actual classification adopted necessarily resting with the medical boards. The subjoined form, which was filled up in the case of every recruit examined at the hospital, a copy of which was transmitted to the medical board sending him for examination, will show the character of the inquiry.

DIAGNOSIS

RESULTS OF EXAMINATION:

So far as concerns his heart the above recruit is fit for

Signed

As the result of this work a large number of records have been accumulated, and it is felt that the material thus obtained, if carefully analysed, may assist in elucidating certain problems connected with affections of the heart.

* Dr. Moon left for army service in April, 1917; Dr. Hamill left for army service in July, 1916; Dr. Price was away on leave of absence for six months from the beginning of December, 1916.

Special Nature of Cases Investigated.

It is necessary to bear in mind the general character of the cases dealt with. They are not, and cannot be, an average sample of the population. All recruits presenting themselves had been, in the first instance, examined by boards of competent medical advisers, cases where the heart was obviously normal having been passed by them, if suitable in other respects, as fit for service, and also most of those who showed well marked and definite diseases having been rejected. Consequently, the men referred to the Heart Hospital were only cases about whose fitness there was some doubt, or cases of cardiac disorders in regard to whom there was difficulty in deciding in which category they should be placed. These cases, therefore, may be considered a fair example of the difficulties encountered by the practitioner in cardiac medicine.

It is in this fact that their value, as a subject for investigation, lies. While it is not suggested that the diagnoses of the staff of the hospital are in any way infallible, the facts observed may be taken to represent observations by physicians who have had more than the average experience in dealing with this class of case.

Up to January 14th, 1918, 10,000 different recruits were examined, as well as 181 men already in the army, who were referred for opinion by army medical officers.

In order to eliminate, as far as possible, the personal equation, and to promote a uniform standard, for some months every recruit was examined independently by two physicians, the two working together being varied from time to time.

The average time that each individual recruit was actually under examination was a little over an hour. The taking of histories, x-ray examination, urine examination, and exercise test of about the first thousand was carried out by the examining physicians. After that, these portions of the examination were made by trained assistants. The actual examination by the physician then averaged a quarter of an hour per recruit.

When over 2,000 had been examined conjointly, and there was a probability of a general consensus of opinion having been established, on account of the time required and of the number of recruits, each was examined by one physician only.

Classification of Recruits to August, 1916.

From February 10th, 1916, to August 7th, 1916, the recruits were classified by the authorities according to the following schedule:

1. Fit for general service at home and abroad.
2. Fit for field service at home.
3. Fit for garrison service (a) abroad; (b) at home.
4. (a) Fit for labour purposes (road-making, entrenching, works companies, etc.). (b) Fit for sedentary work as clerk, etc.
5. Unfit for any service.

Results of 3,830 Examinations.

The annexed schedule gives the classification recommended by the examining physician in the case of the 3,830 recruits examined between these dates, classified in periods of 1,000 each.

Table showing Results of Examinations from February 10th, 1916, to August 7th, 1916.

Class.	No. 1-1000.	1000-2000.	2000-3000.	3000-3830.	Total.
	%	%	%	%	%
1	405 40.5	273 27.3	252 25.2	177 21.3	1107 29.0
2	184 18.4	184 18.4	226 22.6	174 21.0	768 20.0
3A	63 6.3	145 14.5	115 11.5	135 16.3	458 12.0
3B	174 17.4	164 16.4	224 22.4	198 23.8	760 19.8
4A	5 0.5	7 0.7	2 0.2	—	14 0.4
4B	114 11.4	163 16.3	125 12.5	107 12.9	515 13.4
5	55 5.5	58 5.8	56 5.6	39 4.7	208 5.4
Total	1000	1000	1000	830	3830

It is interesting to note that there is a steady decline in the proportion of men presenting themselves who were considered fit for full service. Class 1 consists of men who, after the full examination at the hospital, were con-

sidered to have sound hearts, although the less extensive examination at the recruiting office had left some doubt in the minds of the examiners, and in this first group of 3,830 they constitute 29 per cent. of the whole. Classes 2, 3A, and 3B were considered fit for some modified form of combatant service, although they presented evidence of some cardiac abnormality; 1,986 men were placed in these groups—that is to say, 51.8 per cent. of all examined. They were largely men showing the so-called "functional" murmurs and the like. Classes 4A, 4B, and 5, which comprised 737 men—that is, 19.2 per cent.—were considered unfit for combatant service, because in most cases, in the opinion of the examining physicians, definite structural lesions, either valvular or myocardial, or grave functional disturbances, were present. That this class is so small is due, no doubt, to the care with which definite and obvious cases of heart disease had been eliminated by the medical boards.

New Classification from August, 1916.

On August 8th, 1916, the classification was changed, and from then till the present date the following schedule has been in operation:

- A. Fit for general service. Recruit should be fit for general service as soon as trained.
- B. Fit for service abroad, but not fit for general service:
 - (1) In garrison or provisional units.
 - (2) In labour units or on garrison or regimental outdoor employments.
 - (3) On sedentary work as clerks or storemen only.
- C. Fit for service at home only:
 - (1) In garrison or provisional units.
 - (2) In labour units or on command garrison or regimental outdoor employments.
 - (3) On sedentary work as clerks, storemen, batmen, cooks, orderlies, sanitary duties, etc.
- D. Unfit for any service.

It will be observed that A corresponds to 1 in the old scheme, while B1 and C1 correspond to 3A and 3B; B2 and C2 may be taken as corresponding to 4A, and B3 and C3 to 4B, while D is the same as 5.

Results of 6,170 Examinations.

The results of examination from August 8th, 1916, to January 14th, 1918, are shown in the following schedule:

Class.	3830-4000.	4000-5000.	5000-6000.	6000-7000.	7000-8000.	8000-9000.	9000-10000.	Total.

At first the class of men presenting themselves was fairly similar to those dealt with in the last 1,800 in the previous schedule; but, as time went on, fewer and fewer fit men were seen. No doubt this is partly due to the fact that the absolutely fit joined the army early, and that by this time the general standard of the population to be drawn on was lower; but another factor of great importance, so far as these returns are concerned, is that the later numbers contain an ever-increasing proportion of men who had previously been rejected by medical boards and were called up for re-examination. It also seemed to the examining physicians that the medical boards increasingly referred to them men whom they proposed to put in some of the lower categories but who themselves were desirous of being placed still lower, and probably in this way the hospital performed a useful function in convincing many discontented recruits that their cases had been adequately investigated, and their category only decided on after full investigation.

The full-service men on the new classification from August 8th, 1916, to January 14th, 1918, fell to 11.6 per cent. The total rejections remained fairly constant, being

4.4 per cent. as opposed to 5.4 per cent., while those considered capable of some form of combatant service fell from 51.8 per cent. to 40.1 per cent., and the labour and clerical class rose from 13.8 per cent. to 43.9 per cent.

Age in Relation to the Above.

The annexed table of ages shows no striking accumulation of numbers for any particular age. The large number at 18 is accounted for by the calling up of this class, which commenced towards the end of 1916.

Classification of Occupations.

Considerable difficulty was experienced in arriving at a suitable basis of classification of the various occupations. The scheme of classification adopted in the census returns, though very suitable for the purpose for which it was designed, did not bring out the features which are important from the medical standpoint, nor could we find any widely accepted method of classification suitable for our purpose. It was therefore decided to adopt a vertical classification of indoor, partly indoor, and outdoor occupations, subdividing these into sedentary, semi-sedentary, and active, the active being again subdivided into light, medium, and heavy, with reference to the amount of muscular work entailed, while a transverse or cross classification was made dependent upon professions and trades.

Occupations. Summary of Classification.

Total (+ 35) ...	2521	180	1966	2011	675	362	75	327	575	881	10,000	

As was to be expected in dealing with an urban population, those following an indoor occupation greatly preponderate over the outdoor workers, 7,743 being engaged indoors, 439 partly indoors, and 1,733 out of doors; 35 had no occupation; 5,756 were engaged in sedentary, semi-sedentary and light active occupations, while 4,209 followed employments entailing medium or heavy muscular exercise, 2,651 being in the medium and 1,553 in the heavy class. Since the total was 10,000, percentages are given simply by moving the decimal point two places to the left.

Comparison with London Census.

It is interesting to compare these figures with the Occupation Returns for the County of London. Vol. xxiii of *London Statistics*, issued by the London County Council, contains a classification of the employments of the male population of the County of London based upon the census returns of 1911. This classification, unfortunately, does not distinguish between sedentary, light, medium, and heavy work, and the bulking in large groups makes a detailed analysis difficult, if not impossible. Still, some interesting facts may be deduced from a comparison of percentages in the different categories of the London census and of the 10,000 recruits examined.

With this end in view the figures for the occupations of the recruits have been rearranged, so far as possible, on the lines of the London census, so that they may be compared.

The annexed table gives this comparison with the numbers involved.

	London Census, 1911.		Recruits.	
	No. of Men.	Per Cent.	No. of Men.	Per Cent.
I. Professional ...	69,642	5	499	5
II. Domestic ...	58,257	4.2	167	1.7
III. Commercial ...	137,539	9.8	3,616	36.2
IV. Conveyance of men, goods, and messages	246,493	17.5	1,003	10
V. Metals, machines, implements, and conveyances	119,302	8	900	9
VI. Precious metals, jewels, watches, instruments, and games	27,205	1.9	210	2.1
VII. Wood, furniture, fittings, and decorations	60,765	4.3	542	5.4
VIII. Skins, leather, hair, and feathers	19,553	1.4	179	1.8
IX. Textile fabrics ...	22,829	1.6	19	0.2
X. Dress ...	81,730	5.8	355	3.8
XI. Food, tobacco, drink, and lodging	155,493	11	737	7.4
XII. Other occupations ...	412,719	29.5	1,743	17.4
	1,404,262		10,000	

The percentages in Groups I, V, VI, VII, and VIII are sufficiently the same to be regarded as practically identical. The most striking discrepancy occurs in Group III, that of the commercial classes. These constitute only 9.8 per cent. of the male workers of London, while no less than 36.2 per cent. of the 10,000 recruits examined belonged to this category. Groups II, IV, IX, X, XI and XII bulk larger in the census returns than they do among the recruits.

These discrepancies may be due to one or more of several causes. First, our classification may not be quite the same as that adopted by those who compiled the London statistics, but, as considerable care has been exercised in the classification, it is hardly likely that this can account for the great differences. Secondly, it is possible that all classes of the community have not been drawn upon equally for recruits; but an inspection of the list and a consideration of those classes which would be most likely to be exempted does not afford much support to this view, though it may be the reason for the transport workers furnishing fewer doubtful recruits than their proportion in the population would lead one to expect. Taking these facts into consideration, however, it seems legitimate to conclude that there is, on the whole, a greater proportion of doubtful heart cases in some employments than in others. This, however, still leaves it open to question whether this greater incidence is due to men with defective hearts naturally drifting into light

occupations, such as that of a clerk, or whether such occupations themselves lead to any particular form of heart weakness. This point can only be decided by a detailed examination of the incidence of the various forms of cardiac derangement in the various occupations. An attempt to do this will be made later.

EPIDEMIC POLIOENCEPHALITIS.

(SO-CALLED EPIDEMIC BOTULISM.)

BY

CHARLES H. MELLAND, M.D. LOND., M.R.C.P.,

ASSISTANT PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

PART I.

DURING the last five or six months I have seen a number of cases in which paralysis of some of the cranial nerves has been a prominent feature. The cases have been sufficiently numerous, indeed, to warrant the application of the term epidemic. It has been suggested by Professor Hall, of Sheffield, and others in the lay and medical press, that these are, or may be, cases of "botulism," a disease which has been attributed to the eating of food—particularly uncooked ham and sausage—infected with the *B. botulinus*. It is conceivable that the bacillus may effect a lodgement in the alimentary tract without producing any definite gastro-intestinal symptoms, and that the toxin there produced, circulating in the blood, might select for attack certain cranial nerves as does the toxin of diphtheria. But there is little, if any, evidence to connect the recently recorded attacks with any special articles of diet, and the epidemic, in its widespread character, does not resemble that usually associated with poisonous food, but rather suggests the type associated with symptom-free carriers, as is almost certainly the case in poliomyelitis, and in cerebro-spinal fever.

I had, indeed, concluded in my own mind that I had to deal with an epidemic of infective polioencephalitis, using that term to designate an affection of cranial motor centres produced by the same elusive organism that gives rise to epidemic poliomyelitis, and I have expressed that belief in the title of this communication. A weak spot in this suggestion is perhaps the fact that I have not met with an undue number of cases of poliomyelitis, such as one would expect to be associated with an epidemic of polioencephalitis, nor has such frequency of poliomyelitis, I believe, been recorded. Further, the possibility of an access of botulism associated with the considerably increased consumption of tinned meats during the period of restricted supply of fresh meat must be kept in mind.

The following are the only cases which I have kept any available notes. The first does not belong to the present series since it is one that came under my observation over four years ago, but it is obviously a sporadic case of the same nature as those now epidemic.

G. M. P., a girl aged 12, was seen in the out-patient department of the Royal Infirmary on August 29th, 1913. She had had pain in the head for four days and "turning of the eyes" for three days. She had been sick the day before. She was taken to the Royal Eye Hospital, where she saw Dr. Clegg, and by him was sent on to the infirmary. There was then paralysis of the left sixth nerve, which gave rise to convergent squint, and she had marked optic neuritis. She was constipated. During the next fortnight she continued much the same; she was sick once and had pain in the head and also in the arms and back, and then it was noticed (September 12th) that she had right facial paralysis, though not complete. By September 19th this facial paralysis was well again, but on October 3rd, though there had been no further sickness or headache, she had facial paralysis on the left side. After this date she steadily improved; the paralysis gradually passed off, though there was partial atrophy of the left optic nerve.

I showed this patient at the meeting of the Neurological Society held in Manchester in May, 1914, as probably a case of cerebral tumour that had made a good recovery, but the general view of those who discussed the case was that it was one of polioencephalitis, and that the time of year at which it occurred lent support to this view, since August and September are the months in which poliomyelitis and polioencephalitis are most frequent and occasionally assume an epidemic form.

Of the more recent cases which fall into the epidemic group the following are brief notes:

CASE I.

A. S., a boy aged 16, sent to my out-patient department on November 22nd, 1917, by Dr. Senior of Levenshulme. He had been suffering from left-sided facial paralysis for about a week; he had noticed it first on getting up in the morning, and had attributed it to draught from the window at night. He had slight pain in the left side of the face. All the branches of the nerve, both the upper as well as the lower, were involved. In addition, there was paralysis of certain branches of both third nerves on both sides, the right internal rectus and both internal and external recti of the left eye being involved; there was no optic neuritis. There was little, if any, general disturbance. The paralysis got well in about another week—so rapidly, indeed, that Dr. Senior, who had at first feared cerebral tumour, was inclined to regard the condition as hysterical. Some weeks later he had a slight transient recurrence.

CASE II.

B. J., a boy aged 13, an out-patient at the Royal Infirmary, had facial paralysis on the right side, starting about December 20th, 1917. There was but little local pain or discomfort, and no general symptoms. There was no clue as to the origin of the paralysis. He very rapidly improved under the potassium iodide and sodium salicylate, and was discharged cured by February 21st.

CASE III.

G. T., a girl aged 12, seen in my out-patient department on March 28th, 1918, was taken ill about January 14th, 1918, with drooping of both eyelids and pains in the head, particularly at the back of the eyes. She had no vomiting, but had pyrexia, with some delirium and clouded consciousness. She was an in-patient in a cession at the Eye Hospital, the Royal Infirmary, and the Convalescent Hospital. When she came under my care on March 28th there was still some drooping of the eyelids, though they were better than they had been, and there was divergent squint due to paralysis of the left internal rectus. There was no optic neuritis in this case.

CASE IV.

I. A., a girl aged 14, seen in consultation with Colonel Coates on March 25th, 1918. She had some headache about Christmas, 1917, which was put down as probably the result of a fall on the back of the head shortly before. The headache continued off and on for some weeks, but latterly she had had no trouble with it to speak of. Five weeks back, however, she had begun to see double, and Dr. McNabb found that she had optic neuritis and paresis of the right external rectus. During the whole period during which she had the headaches she had not seemed well of herself, but had not been in any way acutely ill, and when I saw her in March, except for some degree of anaemia she appeared in her normal health. The optic neuritis is now (May 11th) clearing up, and the diplopia and paresis of the left external rectus are now well.

CASE V.

W. B., aged 21, came as an out-patient to the Royal Infirmary on April 4th, 1918. He had had a left facial paralysis, coming on without ascertainable cause about ten days previously. He improved very satisfactorily under treatment, and was discharged cured on May 2nd. He never showed any other local or general symptoms beyond the facial paralysis.

CASE VI.

A. C. W., aged 33, a signalman, seen in the out-patient department of the Infirmary on the same date as the above. He had had right facial paralysis, coming on without ascertainable cause, about eight days previously. He has failed to respond to treatment, and up to date (May 2nd) has made practically no improvement.

CASE VII.

E. C., aged 42, seen in the out-patient department at the Infirmary on April 11th, 1918. She had had weakness of the left eyelid coming on gradually for three weeks. She had had headache, but not very severe. On examination, there was complete ptosis on the side, with no affection of any other eye muscles; the pupils reacted normally, and fundi and fields were normal (Dr. J. G. Clegg). She has improved slightly, the droop of the left upper lid being somewhat less than it was; no further paralysis has developed.

CASE VIII.

M. C., aged 41, insurance agent, was sent to my out-patient department at the Infirmary on May 2nd, 1918, by Dr. Blake-more of Tyldesley, with a note suggesting "commencing disseminated sclerosis." He started with right-sided facial paralysis six or eight weeks ago. He was unable to close his right eye and saw double. The facial paralysis has now practically recovered. He had also some slight drooping of the left eyelid, and this, after getting better for a while, had become worse. When seen there was well-marked ptosis. He still had double vision, and there was paresis of the right internal rectus and of both superior recti. There was no optic neuritis. He had had no general symptoms of illness, and, despite the difficulty of seeing clearly, he had continued at his work with assistance.

CASE IX.

M. M., aged 11, seen in consultation with Dr. Barnes of Fails-worth on April 28th, 1918. She had been ill for about fourteen days with pain in the head and mild pyrexia, about 100° F. The pain was mostly about the back of the head and neck, and there had been distinct stiffness of the muscles at the back of the neck. She had vomited once, and the tongue was dirty. There had been a good deal of general malaise, but when I saw her she was better and was sitting up in bed reading and anxious to be allowed up. There was no paralysis of any of the face muscles, nor any complaint of double vision, but she had well-marked double optic neuritis. On May 5th Dr. Barnes informed me that she had since complained of double vision, though there was no recognizable ocular paralysis. The optic neuritis is now beginning to clear up.

CASE X.

Mrs. W., aged 61, seen in consultation with Dr. McLean of Harpurhey on March 20th, 1918. She had had gradually progressive asthenia for two or three weeks with slow mentality and forgetfulness, and slight continued pyrexia. It was difficult to get her to answer any questions about herself, though after I had been with her for a time she roused up to a certain extent, and took some interest in my visit. There was no paralysis of cranial nerves then, and no optic neuritis, but she subsequently developed facial paralysis. She gradually got worse, and sank into a more and more confused and asthenic condition, and died about a fortnight later.

CASE XI.

Mrs. P., aged 62, also seen in consultation with Dr. McLean of Harpurhey on April 3rd, 1918. She had had symptoms of arterio-sclerosis—recurrent headache and dizzy attacks—for two or three years past. For some days before I saw her she had been suffering from headache, and had been dull and confused, and the day before sudden ptosis of the left eye had developed, and she had diplopia, due to fairly complete paralysis of all the straight muscles of the left eye. She complained of a good deal of pain and headache above the eye, made worse on examining for optic neuritis, which was absent. The urine was free from albumin. She had gradually improved, but on May 5th there was still some drooping of the left lid and diplopia.

With the exception of Mrs. W. (Case x) and of G. T. (Case III), the general symptoms have been comparatively slight, certainly not of the severity suggested by Professor Hall in his brief note of the cases he has seen in Sheffield. It would appear as if most of the cases I have seen were of a subacute type.

I have had some doubts as to whether the three cases of simple unilateral facial paralysis should be included, since they differed in no way from the sporadic cases with no ascertainable cause that are of fairly common occurrence. In view of their unusual frequency, however, and of the belief which I know is held by some physicians that facial paralysis is not uncommonly an expression of polio-encephalitis, I have thought well to retain them.

I have some doubts also of the exact nature of the two following fatal cases. In neither of them was there any cranial nerve paralysis, but the progressive asthenia and drowsiness, advancing to coma, without definite evidence of meningitis, have inclined me to believe that they fall into the same category. I may say that I have during the period come across (but not had under my own care) several cases of similar type, some of which have ended fatally, whilst others have got well after being in apparently a dying condition for some days.

CASE XII.

Mrs. N., aged 23, seen with Dr. Kenny of Pendleton on February 16th, 1918. She had started about February 12th with symptoms suggestive of a mild influenzal attack and a temperature of 100° F. On February 13th she was better, but on February 14th complained of headache and began to be drowsy, and when I saw her she was unconscious, though she showed that she could just feel firm nipping of the skin between one's finger nails. Her pulse was fast (120), breathing not faster than normal. There was nothing abnormal to be discovered in the heart, lungs, or elsewhere. The urine was normal. There was no paralysis, and no optic neuritis. Her state of coma steadily deepened, and she died a few days later.

CASE XIII.

L. W., aged 22, seen with Dr. Barnes of Failsworth on March 19th, 1918. She had been ill for about a week, having started with chest symptoms—cough, rapid breathing, and pyrexia. For two or three days before I saw her she had been getting progressively more drowsy and weaker, and finally could not be roused at all. The urine was normal. There was no paralysis, no convulsions or twitching, but as I suspected tuberculous meningitis I took her into the Royal Infirmary under my care. Lumbar puncture yielded clear fluid under moderate pressure, which did not yield any pathological organisms on culture, and did not show the presence of tubercle bacilli or *Diplococcus intracellularis*. Her temperature remained high and

her coma gradually deepened till she died, two days later. The autopsy revealed purulent bronchitis and acute pulmonary emphysema, but there was no meningitis nor any recognizable naked-eye abnormality of the brain or meninges.

NEPHELOMETRIC ESTIMATION OF QUININE
IN BLOOD AND URINE.

BY

I. J. LIPKIN, M.B., CH.B., M.R.C.S., L.R.C.P.,

JOHNSTON FELLOW IN BIOCHEMISTRY,

AND

W. RAMSDEN, M.A., D.M.,

PROFESSOR OF BIOCHEMISTRY IN THE UNIVERSITY OF LIVERPOOL.

THE methods recorded below were devised, amongst others, in the course of work undertaken at the request of the Medical Research Committee. They are published at once in the hope that they will be useful to others who are investigating the treatment of malaria by quinine. A fuller account of these and other methods will appear in the *Annals of Tropical Medicine and Parasitology*.

By the following procedure estimates of small fractions of a milligram of quinine can be made with an error of less than 5 per cent. It has been found invaluable in dealing with such small amounts of the alkaloid as are contained in 5 c.cm. of human blood, when no other methods would have the necessary delicacy. It has also, by reason of its rapidity, proved very useful for approximate estimations of quinine in urine. Its success is due (1) to the great delicacy given to the Tanret turbidity test by using purified ether and by dissolving the quinine in saturated ammonium sulphate solution; (2) to the observation that comparisons of the opalescences of two suspensions can be made with greatly increased accuracy when the tubes are illuminated by a band of light admitted through a narrow adjustable slit.

Estimation of Quinine in Blood.

Five to ten cubic centimetres of blood are removed from the patient by a syringe, ejected at once into a weighed flask containing 2.5 to 5 grams of solid ammonium sulphate and 10 c.cm. of a saturated aqueous solution of this salt containing 0.6 per cent. H_2SO_4 , and the flask is re-weighed. Boil for two minutes, shaking all the time, and pour off the liquid portion while hot into a small Gooch crucible under suction. Catch the filtrate in a test tube and transfer it to a 50 c.cm. stoppered cylinder. Add 10 c.cm. more acidulated ammonium sulphate solution to the original flask, boil and filter as before. Wash the residue on the crucible twice with the hot filtrate before adding it to the original filtrate. Repeat the boilings with three further lots of acidulated ammonium sulphate solution, on each occasion washing the residue on the crucible two or three times. Cool the filtrate, alkalize it with strong ammonia and extract with four 7 c.cm. lots of purified ether (*v. infra*), removing each lot as it separates, and transferring it to one of a special series of test tubes gauged for nephelometry. Evaporate off the ether on a hot water bath, taking care to avoid loss by spurting—the tube now contains the whole of the quinine of the original blood. Control experiments with normal blood have shown that it contains no substance giving turbidity with Tanret's reagent. The test tubes are of thin-walled colourless glass, and have a diameter of about 13 mm. They are carefully selected so as to be equal in calibre in the lowest two centimetres of the cylindrical portion, this equality being ascertained by means of a suitably thick piece of glass tubing surrounded at its lower end by a half-centimetre length of thick black rubber tubing.

The nephelometer consists essentially of a well made dull-black parallel ruler, the lower bar of which is screwed horizontally to a wooden supporting open framework (for example, a photographic half-plate printing frame), which bears also a small shelf level with the lower edge of the ruler. By means of vertical cardboard screens light is blocked off from all but a middle portion of the slit two test tubes wide. The light should be strong. Between it and the slit is interposed a piece of opal glass or white semi-transparent paper. The ends of the test tubes rest on the transverse shelf referred to above, their sides are

kept in close contact with the face of the ruler by means of rubber bands or brass springs screwed to the ruler or the frame.

Observations should be made in a dark room, and the width of the slit giving optimum results should be chosen empirically. The light should be fixed in position relative to the slit.

The quinine obtained from the blood is dissolved in 10 c.cm. of saturated ammonium sulphate solution, and 5 c.cm. of the solution transferred to another of the gauged test tubes. Into five other test tubes of the series are introduced 5 c.cm. of various standard solutions of quinine in saturated solution of ammonium sulphate of strengths increasing from 1 mg. in 500 c.cm. to 1 in 100 c.cm. To each of the six test tubes is then added 0.05 c.cm. of Tanret's reagent and thoroughly mixed at once by shaking. After a quarter to half an hour the tube is "matched" with the standards in the nephelometer, and thereby an approximate idea of the strength of the quinine is acquired. If this is less than 1 mg. in 500 c.cm. the turbidity will be too slight for any but very rough estimation. If more than 1 mg. in 100 c.cm., dilute the remaining 5 c.cm. of quinine solution with 10 c.cm. of saturated ammonium sulphate solution, take 5 c.cm. of the diluted solution and add Tanret's reagent, mix thoroughly, and match with a series of fresh standards. The dilutions at which we find our judgement of turbidity most accurate, using 13 mm. test tubes, lie between 1 mg. in 200 and 1 in 300 c.cm. The final matchings are made with a series of standard quinine solutions of which the strengths decrease from 1 mg. in 200 c.cm. to 1 in 300 c.cm.

Results Obtained with Pure Quinine.

The alkaloid was given dissolved in a saturated watery solution of ammonium sulphate; 5 c.cm. of the solution was taken for each estimation.

Given Milligrams in 5 c.cm.	Found Milligrams in 5 c.cm.	Percentage Error.
0.0200	0.0192	- 3.9
0.0222	0.0217	- 2.2
0.0233	0.0227	- 2.5
0.0222	0.0217	- 2.2
0.0192	0.0189	- 1.7
0.0200	0.0200	Nil
0.0200	0.0202	+ 1.0
0.0250	0.0254	+ 4.2

The observer did not know the correct results beforehand. Those shown above were obtained in a preliminary trial with test tubes gauged only externally.

We have no doubt they can be improved on, and also that, with suitable flat-bottomed tubes 2.5 c.cm. of solution would suffice, in which case it would be possible to estimate $\frac{1}{10}$ mg. of quinine with the same degree of accuracy.

Results with Defibrinated Sheep's Blood to which Known Amounts of Quinine Solution had been added.

Five cubic centimetres of blood were used for each estimation.

Milligrams of Quinine given in 5 c.cm. of blood.	Milligrams Found.	Percentage Error.
0.0303	0.0312	+ 3.1
0.0200	0.0192	- 3.8
0.0200	0.0196	- 2.0
0.0178	0.0172	- 3.5

The amounts shown are such as do actually occur in the blood of patients taking large doses of quinine.

Nephelometric Estimation of Quinine in Urine.

To every 100 c.cm. of urine add 5 c.cm. of 25 per cent. solution of neutral acetate of lead, containing also $2\frac{1}{2}$ per cent. of acetic acid. Mix and then add 5 c.cm. of saturated watery solution of ammonium sulphate. Filter until a clear filtrate is obtained. Test it for absence of lead by receiving a drop on filter paper moistened with a sulphide solution. If lead is found (very exceptional), the above

defaecation process must be omitted, although troublesome emulsions with ether may then be expected. Reckon 100 c.cm. of filtrate as representing 92.3 c.cm. of the original urine.

Test the filtrate with Tanret's reagent; if it gives any turbidity, dilute it with known volumes of water until it just ceases to do so. This is necessary because the 10 c.cm. of saturated ammonium sulphate solution added to the quinine extracted will dissolve only about 1 mg.

Take 10 c.cm. of this "defaecated" (and, if necessary, diluted) urine in a small stoppered cylinder, and filter; dissolve in it 5 grams of ammonium sulphate. Extract with three successive 7 c.cm. lots of purified ether, and so get rid of any "oily matter." Alkalize it with strong ammonia solution, and extract the quinine with three successive lots of ether, transferring each lot as removed to one of the gauged test tubes. Then proceed as already described for blood estimation.

Estimation of Quinine in Urine.

Milligrams of Quinine given in 10 c.cm. Urine.	Milligrams of Quinine found in 10 c.cm. Urine.	Percentage Error.
0.1000	0.0995	- 0.5
0.058	0.0552	- 6.1
0.0833	0.0832	- 0.2
0.1205	0.1232	+ 2.2
0.0400	0.0401	+ 0.2

Tanret's Reagent.

Dissolve 1.35 grams of mercuric chloride in 70 c.cm. of water, and 5 grams of potassium iodide in 20 c.cm. of water in a 100 c.cm. measuring flask. Pour the mercuric solution into the iodide solution under agitation and fill up with water to the mark.

Purification of Ether.

One litre of methylated ether is shaken up thoroughly for five minutes with four successive 100 c.cm. lots of saturated aqueous solution of sodium bisulphite in a separating funnel, allowing half an hour for each separation before running out the watery solution. Wash with 50 c.cm. of half-saturated sodium chloride solution. The ether is then shaken with 50 c.cm. of water *plus* a little phenolphthalein and enough sodium hydrate solution to give a permanent alkaline reaction. The separated ether is further purified by distillation. It must give no reactions for aldehydes or ketones, as otherwise a Tanret turbidity with the residue of an ether extract would be inconclusive, and nephelometric estimations of quinine would be inaccurate.

As a supremely delicate test for ketones the mercuric cyanide reagent of Scott Wilson can be strongly recommended. As a test for aldehyde (probably much less sensitive) the well-known Schiff's sulphurous acid fuchsin solution may be used.

The ultimate criterion should be that no turbidity develops when the ether is shaken with *excess* of the Scott Wilson reagent.

Scott Wilson Reagent.

Mercuric cyanide	0.5 gram
Sodium hydrate	9.0 grams
Water	60 c.cm.
0.7268 per cent. silver nitrate solution	20 c.cm.

The mercuric cyanide and NaOH is dissolved in water, and the silver solution is run in under constant stirring.

THE American National Board for Vocational Education estimates that 100,000 of every 1,000,000 soldiers sent to Europe will return during the first years of the fighting, and that 20,000 of these will need some kind of vocational re-education. A comprehensive Federal scheme for training and placement in wage-earning occupations has been drawn up which includes a central administrative agency in Washington with similar public, semi-public, and private agencies, and the establishment of "curative workshops for the treatment of war cripples, together with a complete system providing for subsistence and pay during the period of re-education."

STERILIZATION OF THE SKIN AND OTHER SURFACES BY A MIXTURE OF CRYSTAL VIOLET AND BRILLIANT GREEN.

BY

VICTOR BONNEY, M.S., M.D., B.Sc.LOND., F.R.C.S.ENG.,

ASSISTANT GYNAECOLOGICAL SURGEON TO THE MIDDLESEX
HOSPITAL AND SURGEON IN CHARGE OF ITS MILITARY
BRANCH AT CLACTON-ON-SEA,

AND

C. H. BROWNING, M.D., D.P.H.,

DIRECTOR OF THE BLAND-SUTTON INSTITUTE OF PATHOLOGY,
THE MIDDLESEX HOSPITAL.

THE problem how to effect absolute sterilization of the skin is of the utmost importance in surgery, but it is difficult of solution because all the usually employed antiseptics are more or less strongly irritant, so that their prolonged application for the purpose of seeking out organisms lying beneath the superficial layer of epithelial squames, or sequestered in the sweat and sebaceous glands and the hair follicles, is impossible. Their action is thus limited to the surface of the skin only, and those organisms which lie deeper escape destruction. Moreover, they are rendered inactive by admixture with albuminous substances, so that the blood from the wound, on coming in contact with the prepared skin, immediately neutralizes the small amount of the antiseptic. For example, every trace of the iodine colour has disappeared from the neighbourhood of the wound long before the operation is finished.

It may be argued that the iodine has already sterilized the skin, but this would only be true if the sterilization extended throughout the bacteria-bearing regions of the skin, whereas it is limited to the surface. The result is that the rubbing of the soddened skin surrounding the wound, which is more or less inevitable as the operation proceeds, first removes the layer of superficial sterility and then begins to detach epithelial scales which the antiseptic has never reached. The conveyance of such unsterilized squames into the wound is a potential cause of sepsis.

To avoid such conveyance the modern surgeon attaches sterilized towels to the edges of the wound. Fixation of the towels so as absolutely to cut out the skin is simple in straightforward operations where little manipulation of the wound is needed, but quite the reverse in certain prolonged and difficult operations involving much manipulation, and it is in such that perfect aseptic technique is most particularly desirable. The use of sterile towels to cut out the skin has the further disadvantages that they add a complication to the general technique, tend to handicap the surgeon, and increase the expense—a matter of no small moment to hospitals nowadays.

One of us (V. B.) carried out a number of experiments aiming at cutting out the skin surface altogether by covering it with a layer of impermeable varnish; a number of varnishes were used, the basis of them all being asphalt dissolved in various volatile media, to which was added in different experiments mastic, collodion, and caoutchouc. The experiments failed; although the desired result was attained so long as the skin was smooth and dry, yet when it was sweaty or crinkled, as in the case of the abdomen of parous women, the varnish before the close of the operation began to peel off at the edges of the wound.

In consequence, one of us (C. H. B.) suggested the use of a strong solution of crystal violet and brilliant green to produce not only a sterile, but an actively antiseptic condition of the skin, since these substances are both extremely potent antiseptics,¹ and at the same time devoid of irritating effect on the skin when applied in high concentrations. The method which we have employed, and which has been used as a routine at the Middlesex Hospital by one of us (V. B.) for the last two and a half years, is as follows:

The solution contains 1 per cent. of a mixture of equal parts of crystal violet* and brilliant green† dissolved in equal parts of rectified spirit and water. (The powder is dissolved in the undiluted spirit first of all and the water

then added.) Six hours before the operation (except in certain cases) the solution is painted over the skin of the operation area; a compress of lint soaked in the same and covered by a sheet of waterproof batiste, is then applied and kept in position by a binder or bandage. This compress is removed on the operating table and no further painting done. The result is that the skin is stained an intense violet-black; the staining remains unchanged throughout the operation and indeed for a week or two afterwards.² This prolonged application of the antiseptic produces no irritation of the skin, nor of more sensitive surfaces such as the vulva and vagina.

The theoretical advantages of an antiseptic capable of being applied in such concentration and over such a period are obvious. The epithelial squames throughout the entire thickness of this layer become permeated with the dyes. Should a squame become detached and conveyed into the wound it carries with it a definite amount of a potent but practically non-irritating antiseptic, and the skin surface exposed is not merely initially sterilized, but remains antiseptic throughout the operation.

The clinical results accord with the theoretical. The advance made is chiefly apparent not in the average surgical case in which healing was rarely unsatisfactory with the older methods, but in certain operations in which infection of the wound is specially liable to occur. Thus the healing in cases of the radical extirpation of carcinoma of the cervix, an operation in which suppuration in the operation area has been a not uncommon complication, has immensely improved. In these patients not only is there a special liability to transference of skin organisms into the parietal wound on account of the prolonged operation and the amount of manipulation required, but there is a very definite risk of virulent organisms being transplanted from the divided vagina into the operation area. Various methods aiming at preliminary sterilization of the vagina have been employed in the past, but none of them has been so successful as that we now employ—namely, packing the vagina for six hours beforehand with gauze soaked in violet-green.

Further, a marked advance has been shown in the progress of cases of operations involving the perineal, perianal, vaginal and vulval regions, areas the sterilization of which has hitherto been impracticable. Owing to the absence of irritant effect violet-green can be applied to these parts by compress or pack for the same length of time as it can be applied to the abdomen, the leg, or the arm.

Bacteriological Tests.

In order to test bacteriologically the value of violet-green as a skin sterilizer we have made cultures from a series of patients prepared for operation with this antiseptic. The cultures were taken in the following manner: With a sharp needle the skin was deeply scratched, not merely stroked, and the surface of an agar plate inoculated; the needle was then re-sterilized, the skin again scratched, and the plate again inoculated, and so on up to four times for each case. The object of this procedure was to obtain cultures, not merely from the surface of the skin, but from the deeper epithelial layers, and, further, to make the inoculation from each separate scratch act as a control to the others on the same plate. In each patient two areas of skin were chosen, the abdominal skin and the perianal skin, and separate plates were used for each area. The perianal skin was specially selected as being the most bacteria-laden portion of the external surface of the body, and therefore as testing the efficacy of the sterilizing agent in the most rigorous manner.

The violet-green was applied to the abdominal skin for six hours in the manner already described, but only for three hours to the perianal and perineal regions, so as not to interfere with micturition. Our results are as follows:

Violet-green—abdominal skin	22 cases
Result: No growth at all in	22 "
Violet-green—perianal skin	20 "
Result:		
No growth at all in	17 "
Growth in two of the four streaks in	1 case
Growth in one of the four streaks in	2 cases

The growths that occurred in the last two cases were due to the needle being drawn absolutely through the

* The substance employed should be hexa- or penta-methyl violet or a mixture of these.

† Specified as brilliant green sulphate zinc-free.

² If desired the colour may be removed by rubbing the surface with hypochlorite solution, for example, "Eusol."

anus, a recess into which it is impossible to be sure the antiseptic has thoroughly reached. The streaks corresponding to such passage of the needle showed growth, whilst the others did not. This mistake was avoided in the control experiments.

The following control experiments were carried out:

The perianal skin was untreated in 6 cases. Result: Growth in all four streaks in all cases.

The perianal skin was treated with iodine in 10 cases. The skin was painted with 2 per cent. iodine solution in rectified spirit one hour beforehand and again painted immediately before making the cultures—three streaks only to each case.

Result:

No growth at all in	1 case
Growth in all three streaks in	3 cases
Growth in two streaks in	3 "
Growth in one streak in	3 "

The very marked superiority of violet-green over the commonly used iodine is strikingly demonstrated.

For further experimental proofs of the superiority of the violet-green mixture as a means of effecting both thorough and rapid sterilization of the skin we are indebted to the observations of Drs. J. Walter McLeod and R. E. Bevan Brown (unpublished).

The method which these workers adopted was to cut a portion of skin from an amputated limb into portions, which were then placed in sterile Petri capsules. A loopful of a dense emulsion of bacterial culture, faeces, etc., was smeared on the centre of each piece and the surface was allowed to dry. Then the antiseptic was applied either by dropping it on to the surface or by laying on the skin a small piece of lint soaked in the antiseptic solution. At the end of the period of application excess of antiseptic was washed off with spirit and the latter was allowed to evaporate; after the surface had dried, a loopful of sterile peptone water was vigorously rubbed over the treated surface, and the loop was then used to inoculate the test medium. By the application of violet-green, skin inoculated with emulsions of faeces or of soil was completely sterilized, as tested both in aerobic and anaerobic cultures, after twelve to fifteen minutes; *B. tetani* and two strains of *perfringens* type were also killed in fifteen minutes. A 2½ per cent. solution of iodine in spirit was equally effective under similar conditions; but when iodine in 1 per cent. strength was tested on *B. perfringens* it was found to be a less efficient antiseptic than violet-green. The superiority of violet-green was also strikingly apparent in the case of certain resistant organisms; thus, a sporing aerobic bacillus of a type akin to *B. subtilis*, which was very resistant to sterilization by heat, was not killed after ten minutes' application by such practically impossible antiseptics as a saturated solution of iodine in chloroform, 33 per cent. bromine in chloroform, formaldehyde (40 per cent.), liquefied carbolic acid, 5 per cent. hydrochloric acid in saturated watery solution of corrosive sublimate, or 10 per cent. nitrate of silver; 5 per cent. picric acid in spirit, 10 per cent. lysol, 2 per cent. hypochlorous acid, 15 per cent. nitric acid in spirit, also failed to effect sterilization in five to ten minutes; strong tincture of iodine applied for one hour had no obvious effect on this organism, but after twelve hours' application produced sterility. On the other hand, the violet-green solution sterilized the skin after acting for fifteen to thirty minutes.

Streptococci and staphylococci are among the most susceptible organisms to these dyes, hence the above results apply *a fortiori* to those organisms.

MEDICAL, SURGICAL, OBSTETRICAL.

MYOPIA AND MYOPIC ASTIGMATISM IN RELATION TO THE GLARE OF MESOPOTAMIA.

DURING at least nine months of the year the glare experienced in Mesopotamia is a very real trouble. It is with a feeling of great relief that the first rain is greeted; it comes in December and reduces the glaring white of the soil to a muddy brown colour. The country round Basra consists of the river, the Shatt-al-Arab, with a belt of palm trees of varying depth, and then the desert. The date palm is practically the only tree in this part of the country, and its fruit is the principal wealth of the land, but it is an unsatisfactory tree for giving shade, and is usually so covered with dust as to have a greyish colour which gives no rest to the eyes.

The troops are supplied with glare protectors fitted with a green-tinted glass. There can be no question of the comfort that these afford and of the feeling of coolness

experienced on putting them on. Some medical men have asserted that the wearing of glare protectors is as important a prophylactic against heat-stroke as a sun helmet. This, I think, is far too positive a statement. It is generally accepted, after the experience of last summer, which was an unusually severe one, that when a man who has not unduly exposed himself to the sun is attacked by heat-stroke of the apoplectic form he is at the time suffering from some form of toxæmia. In this area the cause of the toxæmia was usually the early stages of sandfly fever or malaria, but alcoholism and even constipation were often the underlying factor.

The point which I wish to bring forward is that persons with myopia, and especially with myopic astigmatism, suffer to a very marked extent from the glare, often to such an extent as to render them useless for any outdoor employment. Men with high degrees of myopia in this country are of little use. Even with glare protectors over their correcting glasses or with tinted lenses, they cannot cope with the conditions.

I will report one case of rather exceptional severity, though cases of a similar nature but of less severity came to the eye department at Basra.

Pte. S. stated (May 21st, 1917) that on the previous day, when coming out from church into the sun, he suddenly saw colours and then became blind. He was taken indoors, and in a few minutes he recovered his vision. Shortly after this he went again to the parade ground, when his sight went in a similar manner and has not returned.

On examination, the vision of the right eye was only bare perception of light, and with the left he could count fingers at a few feet. There was some slight conjunctival injection and considerable photophobia. Both pupils were equal and reacted normally. The eyeballs were somewhat tender to pressure, but the tension was normal. He was wearing -7 D. spher. before both eyes. His refraction worked out at -6 D. spher. -2 D. cylinder axis horizontal for both eyes. The fundus of each eye showed a typical myopic appearance with large temporal crescents, but no active disease was seen. The media were clear.

He was admitted to hospital on the same day, put to bed in as dark a corner of the ward as possible, and given a strychnine mixture three times a day. By the end of a week the photophobia and conjunctival injection had disappeared, and the vision had returned completely. He was subsequently evacuated to India.

I am indebted to Lieut.-Colonel Gee, I.M.S., in whose hospital the ophthalmic department is situated, for permission to publish this case.

P. G. DOYNE, F.R.C.S., Captain R.A.M.C.T.,
Ophthalmic Specialist Base, M.E. Force.

PADDING THOMAS EXTENSION SPLINTS BY PARAFFIN WAX.

I WISH to bring under the notice of surgeons using the Thomas extension leg splint a rapid method of padding the groin ring. It consists in first padding the iron ring in the usual way by winding on to it strips of carpet felting about 1½ in. in width. Each layer as it is wound on is sewn with thin thread to prevent it unrolling or shifting its position, and each successive layer is sewn through to the preceding one. The last quarter of an inch of the padding should be flannel or flannelette sewn in the same manner, and continued until the padding is of the required size and shape.

The whole ring is now immersed in melted paraffin wax, or this is poured over it hot until it permeates the whole padding. When dry and hard all excrescences can be shaved off and the waxed surface rubbed smooth. No leather or other covering is used. It is greasy but clean and does not stick to the skin, and is impervious to moisture. The heat of the body keeps the padding in a soft resilient state, and it moulds itself slightly to the body. If soiled it can be washed, or scraped, or shaved to clean it.

Dublin,

R. LANE JOYNT,
Lieut.-Colonel R.A.M.C.

RECURRENCE OF BILIARY OBSTRUCTION BY GALL STONE AFTER REMOVAL BY OPERATION: ACUTE PANCREATITIS: DEATH.

A VERY stout man, aged 53, was admitted to the Royal Infirmary, Glasgow, under my care, on November 26th, with distension of the abdomen, which was tender all over; the bowels had not acted for six days. Tenderness to pressure was most marked over the right hypochondriac

region. The patient was slightly jaundiced, and the stools passed after admission were clay-coloured. He gave a history of having had a shock a year prior to admission, the whole right side being paralysed for a time. He recovered from this, but the action of the bowels was very irregular from that time onwards. A few days prior to admission he passed a large gall stone.

The ordinary cholecystostomy operation was performed, three large and rather soft stones being removed. Care was taken both by palpation and passing a long probe along the duct to ascertain that no stone or other obstruction was left behind. A large tube was left in the gall bladder, from which a copious flow of green bile was discharged; the jaundice disappeared, and the motions were now bright yellow in colour. The patient was thus very well for several days after the operation, and the flow of bile in both directions, was abundant.

Shortly after the administration of a liver pill containing acid sodium oleate, etc., he again complained of pain in the region of the liver—much more severe, on this occasion; he became markedly jaundiced, and the stools were clay-coloured once more. He died shortly after.

On *post-mortem* examination a stone was found impacted in the papilla of the common duct, which projected prominently into the duodenum. The liver was soft and fatty. There was marked acute pancreatitis, due probably to the blocking of the duct by the gall stone, and extensive fat necrosis.

It would appear almost certain, both from the results of the careful examination made at the operation, and the free flow of bile both into the bowel and through the tube after the operation, that the stone found *post-mortem* came down from one of the bile ducts of the liver, whence, probably, it had been dislodged by the action of the pill. The stone blocking the ampulla of Vater was responsible for the return of jaundice and clay-coloured stools, while it also probably caused a flow of bile along the pancreatic duct thereby setting up the pancreatitis from which the patient died.

JOHN A. C. MACEWEN, M.B., C.M.,
Acting Surgeon, Glasgow Royal Infirmary;
Visiting Surgeon, Glasgow District Hospitals.

A CASE OF ADENOMA OF THE UMBILICUS.

A boy, aged 5, who had, since birth, in the lower half of the umbilicus, a red, raspberry-like tumour, which had persisted in spite of pad pressure and applications of ointments and powders, presented when first seen a red, smooth, oval tumour at the lower border of the umbilicus; its longest diameter was half an inch; it projected one-eighth of an inch above the level of the skin. Except for very slight moisture, there was no secretion from the tumour.

Operation.—The tumour was diagnosed to be an adenoma. The umbilical skin was everted with toothed forceps, and the growth, with a ring of surrounding skin one-eighth of an inch in width, was excised. A probe failed to demonstrate any sinus or canal, but at one spot passed through the thin connective tissue into the peritoneal cavity. A mattress suture approximated the sides of the everted umbilicus. Recovery was uneventful.

Pathological Report.—The following is Captain W. L. Pethybridge's report on his microscopical examination of the tumour:

On longitudinal section, the growth is seen to be an adenoma, attached to a fibrous stalk. At the point of junction of the two parts is a constriction the cavity of which is occupied by squamous epithelium, which also extends for a short distance over the free surface of both the adenoma and the stalk. The glands of the adenoma are tubular, are lined with columnar epithelium, and resemble the glands of the small intestine. They open on the free surface of the tumour. Beneath the glands are bands of unstriated muscle fibres. In places there is some round cell inflammatory exudation.

Remarks.—The condition is one of the abnormalities which result from incomplete obliteration of the vitelline duct, of which the best known is the Meckel diverticulum. In cases such as the above a short piece of the vitelline duct, where it passes through the umbilicus, fails to become obliterated. As the umbilicus closes in, the shallow funnel becomes everted and forms a red velvety tumour, the covering of which is practically intestinal mucosa.

Plymouth.

Reports of Societies.

MOUTH INFECTIONS IN RELATION TO INTESTINAL INFECTIONS.

At a meeting of the Section of Odontology of the Royal Society of Medicine, on May 6th, the President, Mr. J. H. BADCOCK, being in the chair, Dr. NATHAN MUTCH read a paper on infections of the mouth in their relation to those of the gastro-intestinal tract. Almost every organism, he said, which had been identified in the bowel in health or disease had been found also in the mouth or in the food ingested through the mouth. At all times any factor such as alteration in diet, digestion, or motility which changed the conditions in the intestines modified also the bacterial balance. When acidity was excessive the duodenum and jejunum were sterile or contained small numbers of strongly acid-resisting yeasts. When gastric hydrochloric acid was very low the number and variety of jejunal organisms were greatly increased. At lower levels stagnation allowed the destruction of the majority of these bacteria by the minority, which found the environment fitted to their free multiplication. Parasitic strains of bacteria, arising from dental defects and swallowed, might infect the mucosa and prolong constitutional disease for years after the restoration of the mouth to health, as occurred in rheumatoid arthritis. The causal bacteria of chronic intestinal infection could live on living or dead tissue; when conditions in the tissues were adverse they continued as saprophytes on the surface; when the exudates and residues were unsuitable for growth, the race was continued amongst the tissues, so that infection continued until both environments became unsuitable at the same time. This rarely occurred spontaneously, and natural cure was uncommon. Infection, either in the mouth or intestine, depressed the general tone and favoured increased invasion at the other focus. Hence improvement was effected in buccal infections by treatment of the bowels, and vice versa. One of the commonest micro-organisms to establish chronic infective foci simultaneously in the mouth and intestines was *Streptococcus pyogenes longus*. In comparison with bacteria of the *B. coli* group the numbers of streptococci were small, but in disease they might increase greatly until they became the predominant colonic aerobes, in extreme cases replacing the colon bacillus almost completely.

Among the factors favouring streptococcal growth in the digestive tract local delay was the most important. With a delay of six hours, fast-growing cocci increased four-thousandfold. Considering the lower ileum and colon only, deficient assimilation of food in the upper parts of the digestive tract was the second essential factor. The more easily digestible the food and the greater the efficiency of mastication, the poorer were the residues upon which the ileo-colonic flora could rely. The products of meat proteolysis induced much more rapid growth than did the products of casein digestion. Although a rich nitrogenous basis was required for streptococcal growth, the presence of carbohydrate was needed for its dominance over members of the *B. coli* group.

The harmful influences determining the first departure from health were those which gave rise to chronic intestinal stasis, and thereby produced secondary foci of stagnation. The densest stream of harmful streptococcal strains flowed from the mouths of patients suffering from infections of the teeth, gums, tonsils, nose, and pharynx. From centres of saprophytic growth in the chyme of the ileo-caecal region long-chained cocci invaded the mucous membrane, and so opened up new channels for their dissemination in the tissues, where they continued life as parasites, exchanging their strife against rival bacteria for one against the defensive processes of the body. Mouth infection again aided them by inducing negative immunity phases from time to time, and thus allowing them greater opportunity of establishing themselves in the mucosa, and they then spread upwards and downwards. Organisms streamed from the infected mucosa along the lymphatics to the neighbouring glands. Alimentary and systemic infections with streptococci, often glycolytic in nature, were associated with a great variety of minor and major gastro-intestinal disturbances, muscular rheumatism,

rheumatoid arthritis, slight and severe anaemias, chronic ulcerative endocarditis, and chronic nephritis of mixed type, etc.

Treatment of the mouth could do much to benefit a great variety of morbid states, but derangements in the lower alimentary tract imposed strict limits to the degree of improvement which could be effected in this way.

The rational treatment of chronic infective conditions of the digestive tract, such as streptococcal disease, was to attack the mouth infection vigorously by local measures, but at the same time to employ every possible therapeutic measure, whether diet, drugs, operation, massage, or vaccines, for the correction of the lesions in the stomach and intestines.

DISCUSSION.

Major H. P. PICKERILL said that as the result of experiments on animals he had found that the prolonged elimination of the glosso-pharyngeal reflex had had the following effects:

1. The animals died within six months.
2. Their weight equalled one-quarter to one-half that of the controls.
3. Starch and calcium were excreted in excess.
4. The salivary glands were undeveloped (in ratio to body weight).
5. The animals developed a polyneuritis, from which they apparently died.
6. *Post mortem* there were gastric lesions. Ulcers were constant, and there was dilatation and pyloric stenosis.

He had injected endotoxins and exotoxins from the human mouth into the jugular veins of rabbits, and found that endotoxins produced a rise of blood pressure and exotoxins a fall of blood pressure. He had administered daily by the mouth 1 c.cm. of broth culture from carious teeth to rabbits. This was followed by malaise, anorexia, and diminished defaecation, as was shown by human beings with oral sepsis and stasis. He thought the explanation was something as follows: The ingestion of non-acid or alkali substances was followed by glosso-pharyngeal depression, and this in turn by diminished alimentary secretion, oral and intestinal stasis, toxic absorption, and sympathetic nerve stimulation, intestinal dilatation, and viscous, scanty saliva. In this way a vicious circle was formed which could start at any point. Mr. DOUBLEDAY also took part in the discussion, and Dr. MURCH replied.

BONE GRAFTING IN UNUNITED FRACTURES OF THE MANDIBLE.

At a meeting of the Clinical Section of the Royal Society of Medicine, held on May 10th, Surgeon-General H. D. ROLLESTON, the President, being in the chair, Mr. PERCIVAL P. COLE showed nine cases to illustrate the results of bone grafting in ununited fractures of the mandible. The cases included examples of free transplants from tibia and rib and several treated by the author's method of employing a pedicled graft derived from the lower jaw itself. The cases were inspected, and the results obtained were regarded as very satisfactory. Mr. Cole, in describing the operation devised and practised by him, said that a thick, well-nourished bone fragment could be detached from the basal margin of the body of the jaw. The blood supply of this fragment was maintained through a muscular pedicle consisting of platysma, deep cervical fascia, and the anterior belly of digastric. The longest fragment thus detached measured 4 cm. The great majority of ununited fractures exhibited a loss of bone that could be bridged easily by a graft of that length. Hence the operation had a wide range of applicability. Owing to the vitality of a graft of this nature results were obtained with more certainty and greater rapidity than by the use of a free bony transplant. Mr. Cole dissented from the view that free transplants failed so frequently that they should only be employed as a last resort. He had had no failure in cases where pedicled grafts had been employed, and was able to record 70 per cent. of successes in cases treated by free transplants.

At a recent meeting of the principal authorities and leading citizens of Naples a committee was formed for the establishment of a large children's hospital in that city. Professor Antonio Cardarelli, Senator of Italy, was elected honorary president.

Reviews.

TRANSFUSION OF BLOOD.

IN an interesting historical note in BERNHEIM's handbook on *Blood Transfusion*¹ the subject is divided into four periods: the first from 1492, when an attempt to save the life of Pope Innocent VIII was made, with the result that the three donors died, up to Carrel's work on the surgery of the blood vessels; the second period of direct transfusion rendered possible by Carrel's genius and developed by Crile's enthusiasm; the third period of indirect transfusion of whole blood by means of Lindemann's syringe and of the methodical determination of the haemolytic and agglutinative relations of the bloods of the donors and recipients; and, lastly, the recent epoch of indirect transfusion with the aid of anti-coagulants. In dealing with the control of haemorrhage the author states that rabbit and horse serum are generally of no value, dismisses calcium lactate as a doubtful prophylactic and of no use when bleeding has started, and points out that too much has been expected from saline solution, examples being given of its failure and of its inferiority to blood transfusion. In the section on the indications for transfusion the lines laid down by Libman and Otterberg are very closely followed, and reference is made to the suggestion that a systolic blood pressure of 70 mm. Hg is the danger limit which should call for immediate blood transfusion regardless of the other features of the case.

The chief dangers attending blood transfusion are haemolysis and agglutination, the former being by far the more serious; the precautionary tests to be carried out before transfusion so as to avoid these complications are detailed in the appendix, where Moss's classification of human beings into four groups according to their isoagglutinins is reproduced. Though *a priori* embolism should be common, in practice it is very seldom seen. Examples coming under the author's notice of the transmission of syphilis and of malaria—accidents very rarely reported—are mentioned, and the results of a collective investigation into 800 cases of transfusion are quoted. The details of the method are well illustrated by figures, and the author humorously mentions that he thought he had invented a method which he however found had been actually described two and a half centuries earlier. The sodium citrate method of indirect transfusion, which it is thought will probably supersede the others, is discussed and compared with the results of transfusion of untreated whole blood: paradoxical as it seems, the coagulation time of the patient's blood is shortened, not prolonged, after the transfusion of citrated blood, but a febrile reaction with a rigor follows transfusion of citrated blood much more often than one of untreated whole blood. The various conditions, such as acute haemorrhage and shock, anaemia, haemorrhagic diseases, and leukaemia, for which transfusion is indicated, receive individual attention.

The author had to leave so suddenly for foreign service with the Johns Hopkins Base Hospital unit that he was unable to give his treatise a final revision, and this probably accounts for some delay in its appearance, but he may be heartily congratulated on his useful and practical contribution.

HOSPITAL SHIPS.

IN the preface to his handbook on the *Fitting Out and Administration of a Naval Hospital Ship*,² Fleet Surgeon SUTTON, R.N., states that he is writing from an experience of three and a quarter years. The book contains four sections. In the first, allusion is made to hospital ships of the sailing ship era, and a summary is given of the stages by which the modern hospital ship has been evolved. The chief factors which have determined the direction of development in the past are traced, and a forecast made of the directions in which developments are likely to proceed in the future. There is a brief historical account of the

¹ *Blood Transfusion, Haemorrhage, and the Anaemias*. By Bertram M. Bernheim, A.B., M.D., F.A.C.G., Instructor in Clinical Surgery, the Johns Hopkins University, Philadelphia and London: J. B. Lippincott Company. (Pp 259; 18 figures. 18s.)

² *The Fitting Out and Administration of a Naval Hospital Ship*. By Edward Sutton, Fleet Surgeon R.N., S.M.O. R.N. Hospital Ship *Passy*, etc. Bristol: John Wright and Sons; London: Simpkin, Marshall and Co.; Toronto: The Macmillan Co. of Canada, 1918. (Demy 8vo, pp. 110; 28 figures.)

origin of the Red Cross organization, and the rules by which the employment of hospital ships ought to be governed are given *in extenso*. The uses to which hospital ships may be put in war are stated and possible irregularities discussed, as also the question of confiscation.

The principles which should guide the selection of a mercantile marine vessel for conversion into a hospital ship are discussed under two headings: the choice of a suitable vessel, and the location of specific hospital requirements. To write a useful description of the converted hospital ship is far from easy, but the author's scheme is good. He first devotes a chapter to the steamship *Drina* prior to conversion, and in the succeeding chapter describes the same vessel after conversion. This will be a valuable guide to any one who may have to carry out such a conversion. Every measurement likely to be wanted in the construction of the wards and different special departments—the operating theatres, store rooms, etc.—with all their fittings, seems to be given.

The next section deals entirely with the working organization of a hospital ship. The method of embarking patients is described under four headings: (1) Means of getting the patient (a cot case) inboard; (2) allocation of his bed; (3) registering the occupation of that bed; and (4) stowage of the man's effects. A new and admirable modification of the "service" cot carrier is described; the innovation is that both ends are detachable, and there are wooden rollers on its floor; photographs and a drawing to scale are given. The organization for evacuation is simple and original. By means of a system of labels and discs, which is described in detail, the considerable amount of clerical work necessary for papers which must be sent with patients can be quickly compiled. In any service institution the stores department is very important, and here a novel system is described whereby the fluctuation in the stock of each article is automatically recorded: the same scheme also enables the person responsible for ordering the fresh stores to see at a glance how much of each article is required.

The author has had experience of three separate hospital ships, and this alone entitles him to speak with authority on his subject. His book contains a great deal that is new, and he has displayed considerable genius in evolving a remarkable organization for the working of a hospital ship. The value of the book is enhanced by helpful diagrams and illustrations. It will meet a real want, for we are unaware of any similar publication; we congratulate the author, and confidently recommend his work to the notice of all medical officers—naval or military—who are in any way concerned with hospital ships.

THE GROWTH OF MEDICINE.

THE study of the history of medicine has received a great stimulus in this country by the establishment of a separate section of the Royal Society of Medicine, and there has been a remarkable growth of interest in the subject in America. Recent evidence of this is afforded by a large work compiled by Dr. ALBERT H. BUCK, of the Columbia University, New York, dealing with *The Growth of Medicine*³ from the earliest times to about 1800. The volume, finely printed and illustrated, is the first of a series to be published at the Yale University Press on the foundation established in 1916 as a memorial to three generations of a family of doctors educated at Yale, the Williams Memorial Publication Fund.

Dr. Buck has succeeded in weaving a valuable account from the many sources of information open to him. His history carries the reader through each period of medical progress or recession with equal interest. From its origin in the East when anatomy was unknown and treatment for most part mystic and in the hands of the priesthood, he traces the dawn of clinical observation and illustration in Greece, and incidentally refers to the practice of offering votive tablets to Aesculapius, some of which have been found to portray the morbid conditions of the petitioner. A most admirable model of a face distorted by paralysis, discovered some years ago and now in a German collection, is given as an illustration. With the era of Hippocrates a

great stride forward was made, and all readers of his aphorisms must recognize that many of the rules of conduct laid down for physicians are as applicable at the present day as they were in 400 B.C.

Athens in time gave place to Alexandria as a seat of learning and a great clinical teacher arose in the person of Herophilus; many of the subjects discussed under his auspices have remained undecided to the present day. The varying experience of a vast number of writers has tended to prevent any common agreement. Specialism began to be practised just before the beginning of the Christian era, and once again the chief seat of learning migrated and settled itself in Rome. The most prominent figure of that period was Aesclepiades, whose teaching, entirely founded on observation and without means of verification by *post-mortem* examination, contained much that survived through succeeding centuries. In the second century the advent of Galen exercised a great influence upon medical thought and practice. His voluminous writings, which have been so often translated, have been perhaps more highly appreciated by later generations than by the readers and pupils of his own day. Like many other pioneers, he was far in advance of his period, and obviously had that strong belief in himself which has proved essential to great teachers in all times.

To follow Dr. Buck through each successive wave of advancement and recession, to Constantinople, to Persia, and to the final settlement in Northern Italy and Western Europe generally, would call for more space than is available. It must suffice to record that every step forward, or backward, is traced with the same thoroughness, apt quotations being inserted and well-executed illustrations being supplied of many of the epoch-making events, or of the great leaders in many lands. Some medical historical treasures will probably have been destroyed in the library of Louvain, and notably a finely illuminated edition of Vesalius's works, but its fate is at present unknown. Medical literature has suffered much from the incendiary zeal of invaders at many previous periods of history, but although originals have been lost, the copies laboriously executed by monastic and other hands have remained, and Dr. Buck has done a great service in so classifying and bringing together the scattered records as to form a most interesting and valuable history.

NOTES ON BOOKS.

THE Central Council for District Nursing in London has issued a *Directory of District Nursing*⁴ in London which will undoubtedly be of service to social workers, medical practitioners, and others engaged in the health service of the metropolis. The directory gives the name of practically every street in the administrative county, together with the borough and Poor Law union in which it is situated. For each entry there is a reference number to the index of district nursing associations.

Mr. HAMILTON WHITEFORD has brought together in a small book some practical notes on the diagnosis and treatment of *Acute Appendicitis*,⁵ based on his own experience. After dealing with points in the diagnosis, he passes on to discuss questions of treatment, dealing with them under the heads of general principles—pre-operative, operative, and post-operative. This is followed by a note on some post operative complications. The author is inclined to be didactic on matters which have been much debated in recent years. His general conclusion is that in advanced cases the operator's temptation is to do too much.

⁴ *Directory of District Nursing and Streets List for London*. London: The Botolph Printing Works, 8, Gate street, Kingsway, W.C.2. (2s. 6d.)

⁵ *Acute Appendicitis: Practical Points from a Twenty-five Years' Experience*. By C. Hamilton Whiteford, M.R.O.S., L.R.C.P. London: Harrison and Sons. 1917. (Cr. 8vo, pp. 72. 4s. net.)

THE review which is the organ of the Russian Association for the protection of mothers and infants entered on its third year of life at the beginning of 1918. It is published at Petrograd (Nicolaiievskaja, 49) in two-monthly fasciculi, which form at the end of the year a goodly volume of six hundred pages. The editor is Dr. P. Medowikoff.

³ *The Growth of Medicine from the Earliest Times to about 1800*. By Albert H. Buck, B.A., M.D., Columbia University, New York. Newhaven: Yale University Press; London: Humphrey Milford; Oxford: University Press. 1917. (Med. 8vo, pp. 582. 21s.)

MODERN LANGUAGES AND "MODERN STUDIES."

THE report of the Committee appointed by the Prime Minister in August, 1916, to inquire into the position of modern languages in the educational system of Great Britain is remarkable for the definite recommendation that Latin should not be compulsory, even for an arts course, at any university, and that for the Civil Service (Class I) modern languages, with their history and literature, should be placed on an equality with the similar learning of Greece and Rome. The report should be read in connexion with the report of the Committee appointed by the Prime Minister at the same time to inquire into the position of natural science in the educational system of Great Britain, of which we gave some account on April 20th, p. 459. It also arrived at the specific conclusion that Latin should not be retained as an obligatory subject in the examination for entrance to the medical profession. The report of the Modern Languages Committee is all the more likely to have a profound influence on secondary and university education in Great Britain in that its recommendations seem to be in line with the policy set forth in 1913 by the Board of Education for England and Wales in its scheme of modern studies in the higher parts of secondary schools and the corresponding examination for the higher school certificates. The regulations giving effect to the scheme as a definite plan for the curricula in secondary schools were issued in 1917, and some progress had been made by the end of that year.

How far opinion has moved since the middle of last century is strikingly exemplified in a quotation unearthed by the Committee from a solemn admonition addressed by Mr. Gladstone to the Public School Commission appointed by his Government in 1861. He warned the Commissioners against the "organic rashness" of putting forth a sacrilegious hand to touch the ark of the covenant. Speaking of the relation of pure science, natural science, modern languages, modern history, and the rest, to the old classical learning, he emphatically denied their right to a parallel or equal position. He regarded the position of modern studies as ancillary, and therefore "to be limited and restrained without scruple." He did not rest his case upon the doctrine that classical training should be paramount because it improved memory or taste, or gave precision, or developed faculties of speech; all these he regarded as "but partial and fragmentary statements, so many narrow glimpses of a great and comprehensive truth," which was that "the materials of what we call classical training were prepared, and we have a right to say were advisedly and providentially prepared, in order that it might become, not a mere adjunct, but (in mathematical phrase) the complement of Christianity in its application to the culture of the human being, as a being formed both for this world and for the world to come." As the Committee says, it seems to-day wellnigh incredible that the view that Latin and Greek should have such a monopoly was once held with so much passionate earnestness.

The Committee gives so excellent a definition of the term "modern studies" that it may well be quoted. It understands it to signify "all those studies (historical, economic, literary, critical, philological, and other) which are directly approached through modern foreign languages"; and it adds, what we think has often been forgotten by schoolmasters, that "the study of languages is, except for the philologist, always a means and never an end in itself." Though by this definition English is excluded, the Committee has had to consider English as a rival subject of study, and finds it to be entitled to paramount rights and necessary as a preparation for the study of foreign languages. At the same time, the Committee fully recognizes that language teaching in schools should have a disciplinary and educative aim, and should train the mind, the taste, and the character. Language is a means of expressing thought, and the study of a foreign language, it says, reveals the anatomy of thought. "Each language has its own mode of expression, and the contrast of and comparison of different modes of expression lead to a more accurate sense of logical processes and a closer observation of the finer shades of meaning." We venture to think that this is a most important observation, and that it affords an explanation of the fact that persons who have had a thorough classical education often write excellent English. The reason is not that the languages were Latin and Greek, but that the study was thorough. Nowadays many a boy leaves school to enter on a career in medicine or science without knowledge of the structure of any language, even his own, with which he has only a colloquial acquaintance. The resulting evil amounts to very much more than the loss of aesthetic value; it causes a good many medical and scientific papers actually published to be defective in expression and in logical arrangement. The directors of laboratories could tell some queer stories of the state in which the first draft of a paper for publication is sometimes presented to them. But the aesthetic part of the matter is not lightly to be set aside. "The laws of language," the Committee says in an eloquent passage, "are sure and valid, but they are revealed in speech and writing as the laws of nature are revealed in living beings—in a delicate harmony of balanced forces and blended qualities"; so that language has not only a logical and intellectual value, but has also an aesthetic and artistic value.

The Committee is by no means blind to the utilitarian value of even a reading knowledge of a foreign language. No country, it truly says, can afford to rely on its domestic stores of knowledge. The whole civilized world is a co-operative manufactory of knowledge. "In science, technical and pure . . . new researches are constantly leading to new discoveries, new and fruitful ideas are giving new pointers to thought, new applications of old principles are being made, old stores are being rearranged, classified, and made available for new purposes. In this work all the civilized countries of the world collaborate, and in no branch of knowledge, abstract or concrete, disinterested or applied to the uses of man, can the specialist neglect the work of foreign students." In the paragraph from which we have quoted the Committee makes an appeal to the universities to put the study of foreign languages in its rightful place. At present, the Committee says, "one way and another it is certain that modern studies do not at the universities get anything like their fair proportion of the best brains." This is due partly to the defects in the methods of secondary schools, but in large part also to the fact that at the universities few distinctions and prizes are to be won in modern studies during or

at the end of the academic course. Fellowships at Cambridge, and still more at Oxford, are rarely given for modern subjects; and, again, in the highest public competition of the kingdom, that for Class I of the Home Civil Service and the Indian Civil Service, modern studies have hitherto had an entirely subordinate position. The Science Committee held that the state should provide funds for scholarships for boys in the higher classes of secondary schools to encourage them to devote themselves to science. With this the Language Committee agrees, apparently in despair of the universities making use of any of their existing endowments for this purpose, but applies it to modern studies generally. Entrance scholarships would not be sufficient; assistance must be given throughout the course, and there must be prizes at the end equal in value and importance to those offered for classical subjects.

INTRAVENOUS INJECTION IN WOUND SHOCK.

By a curious but happy accident two works on transfusion come almost simultaneously before us. Bernheim's book on blood transfusion, reviewed on page 565, gives an up-to-date account of the practice, while Professor W. M. Bayliss's Oliver-Sharpey lectures are concerned with the contemporary researches carried out by the Special Investigation Committee of the Medical Research Committee, in which he took such an important part. By this coincidence a survey of the subject from the stand-points of practical surgery and of applied physiology is presented. Captain Bernheim, M.O.R.C., U.S.A., author also of *The Surgery of the Vascular System*, summarizes the experience of the past, while the lectures of the distinguished professor of physiology in the University of London point the way to future advances, and are particularly appropriate both as showing the application of physiology to the relief of the emergencies of war and in dealing with arterial blood pressure, a subject to which the late Dr. George Oliver, the founder of these lectures, rendered yeoman service.

Professor Bayliss prefers the term wound shock, introduced by Captain E. M. Cowell, R.A.M.C.(S.R.), in a recent report to the Medical Research Committee, to traumatic or surgical shock, and, after mentioning the primary shock which serves a useful purpose in diminishing the liability to haemorrhage, devotes his attention to the secondary stage of shock. The immediate cause of the low blood pressure is still obscure, but several conditions can be excluded—namely, Yandell Henderson's acapnia; Crile's adrenal exhaustion, because adrenalin is present in excess at the onset of shock; exhaustion of the nerve centres, inasmuch as the reflexes are not diminished to any important degree except when the blood pressure has been low so long that the centres are paralysed from oxygen want; cardiac failure; and paralysis of the arterioles or veins, especially of the abdomen, because direct observation during laparotomies fails to show any abnormal vascular distension. The explanation most in favour is an accumulation and stasis of blood in the capillaries so that it is as effectively removed from currency as it would be by bleeding—Cannon's exaemia. With this deficiency of the circulating blood the blood pressure naturally is low, and as a result the tissues suffer from oxygen starvation, the vasomotor and respiratory centres begin to fail, and being directly dependent on the blood pressure, the excretion of urine and of acid and toxic products falls.

After some discussion Professor Bayliss decides that acidosis, which some observers have regarded as the essential cause of shock, is not a serious factor. This point is important as regards the treatment, for transfusion with sodium bicarbonate has been advocated; but in experimental shock the beneficial results of this remedy have been transient and slight, and this effect may quite well have been due to the volume of fluid introduced. The best means of counteracting the production of acid in the tissues is to increase their supply of oxygen from the blood, and if for other reasons it is necessary to give alkalis the oral route should be adopted.

The light thrown on the treatment of shock is the important feature in these lectures. The true objects in the successful combating of shock—namely, an increased supply of blood and oxygen to the tissues—can be obtained by raising the blood pressure, but vaso-constrictor drugs cut off the access of blood to the tissues, and are therefore inadvisable. The proper course is to raise the volume of circulating blood and thereby increase the blood pressure without diminishing the peripheral flow, and for this purpose it has naturally been assumed that transfusion of blood would be the best means. It is therefore surprising to find that experimentally blood is not so superior to a solution of gum arabic as might be anticipated; thus, if a given case fails to respond to gum solution, transfusion of blood is also ineffective. One explanation appears to be that in ordinary conditions there is a sufficient reserve of haemoglobin to keep the tissues provided with oxygen, even with a diluted blood, provided the blood pressure is not too low and the patient is kept at rest.

The nature and composition of the substitute for blood are important factors; Ringer's solution leaves the vessels in half an hour or so, and as the blood pressure then falls to its former level or even lower it is useless; hypertonic solutions of salt also prove valueless, and the addition of calcium salts to Ringer's solution has not improved matters. A colloid with an osmotic pressure is required, and this is provided by a 6 per cent. solution of gum arabic with 0.9 per cent. of common salt: it does not leave the blood vessels or produce any bad effects, such as haemolysis, agglutination, thrombosis, or anaphylaxis; it maintains the blood pressure indefinitely, and has the great advantage of easy preparation. That physiology applied practically has thus scored a triumph is shown by the report on 250 cases of shock by Captains Hamilton Drummond and E. S. Taylor. In conclusion, Professor Bayliss points out that after very grave haemorrhage transfusion of blood would be preferable; and probably this would also apply in cases in which from repeated small bleedings the reserve of haemoglobin has been brought to a low ebb.

WORK OF THE ARMY MEDICAL ADVISORY BOARD.

THE reconstituted Army Medical Advisory Board, appointed about a month ago, has since met frequently for prolonged sittings, and has had a number of important matters under consideration. Among the subjects on which it has been able to formulate its opinion is that of the arrangements which should be made to enable A.M.D. 1—the department concerned with personnel and the allocation of officers to appointments for which they are best qualified by experience and inclination—to work more surely and rapidly. One piece of machinery which was already in existence, and had proved its usefulness, but is now being extended and completed, is a card index of all officers R.A.M.C., whether regular, retired

pay, Special Reserve, Territorial, or holding temporary commissions. The card index is founded upon a form which medical officers have recently been asked to fill up. In addition to particulars as to name and age, medical school, and qualifications, the officer is asked to state any hospital appointments he may have held, and also any other appointments such as that of medical officer of health, and to give information as to any special training he may have had, research work he may have conducted, or publications he may have made. He is also asked to set out how he has been employed during the war, showing the units to which he may have been attached, the expeditionary force or home command in which he has served, and the nature of the duties performed. These particulars are transferred to an index card. The cards are arranged under names in alphabetical order, the index thus formed being retained in the Director-General's office in London. When an officer is posted to an expeditionary force or command a duplicate is forwarded to the head quarters of the force, where it may be added to, or form the basis of, what may be called a local card index. There is one fairly obvious lacuna in the plan, for an officer suddenly transferred, perhaps in an emergency, from one command to another—say, from a base hospital to some post in an advanced area—will arrive in his new command before the information filed at Adastral House or the head quarters of the command to which he formerly belonged reaches that to which he has now been transferred. We understand, however, that a kind of personal diary or identity book has been prepared and will shortly be issued to every officer in the army, and that in the case of officers R.A.M.C. information as to special experience corresponding to that in the card index will be inserted in it. In addition to the primary card index arranged in alphabetical order of names a second card index will be formed in London in the following way: the forms filled up by an officer will contain, as has been stated, information as to any special work he may have done, whether in one of the clinical specialties, or in bacteriology, or hygiene. The forms, after being used for the purposes of the card index, will be passed on, after a primary classification according to the special experience and attainments stated therein, to a series of specialist committees appointed by the Director-General to advise him on the matter. It will be the duty of the committee to grade the officers having this special knowledge, in accordance with the extent and nature of their experience. Taking bacteriology as an instance, an officer who has been holding an independent position and has shown himself capable of undertaking and directing independent researches will be put in Grade 1; from Grade 1 a selection will be made for higher appointments, such as that of director of a military laboratory. An officer with less experience who has shown himself capable of carrying out investigations and researches under the general supervision of the director of a laboratory will be placed in Grade 2, and will be eligible for employment in a similar capacity in military laboratories. Officers who have gone through a course of training in, say, bacteriology, but have not yet won their spurs in research, will be placed in Grade 3, and will be employed as opportunity may arise as assistants in military laboratories and will be given facilities for undertaking investigations under supervision. The same principle will apply to other specialties. Other matters which have been engaging the earnest attention of the Army Medical Advisory Board are the organization of officers' hospitals in adequate numbers and suitable localities and under efficient supervision; and the establishment of hospitals for dealing with cases of disordered action of the heart or valvular disease, so that men who can be rendered fit may be sent into the combatant ranks or returned to them, or discharged if not likely to become fit. This will probably involve the allotment of beds in selected hospitals and the

establishment of convalescent institutions for each command. A matter which is being taken up immediately by the Board is the treatment and general disposal of gassed cases. The work already done by the Army Medical Advisory Board has justified its reappointment, and it will, we have no doubt, be able in the future to render very valuable assistance to the Director-General and his staff.

MEDICAL NEEDS OF THE U.S. ARMY.

THE Surgeon-General of the United States Army, on April 3rd, made a formal request to the American Medical Association to co-operate, through its central and local machinery, in the work of securing additions to the Medical Reserve Corps, and of keeping the numerical strength of the corps up to the requirements of the service whilst safeguarding the interests of the civil community. On that date the personnel of the Medical Department of the army included 838 officers of the regular Medical Corps, 18,279 officers of the Medical Reserve Corps; together with some 1,300 officers of the Medical Corps of the National Guard and National Army; a Dental and a Dental Reserve Corps, numbering about 5,400; and a Sanitary Corps and Ambulance Service with some 1,200 officers. All officers of the Medical Reserve Corps who have received their commissions and are ready for active service will be required for present needs, while the additions to the United States army during the next few months will necessitate the service of 5,000 medical men who have not yet applied for commissions. It is estimated that the Medical Reserve Corps will need a steady increase of 2,500 applicants a year during the continuance of the war, to replace wastage and provide medical personnel for organizations not yet authorized. The surgeon-general is at present authorized to maintain a strength of 3,600 medical officers in instructional training camps. The War Department desires that the interests of the civil population should be conserved as far as possible and that no enlistments should be made in the Medical Reserve Corps that would "work serious hardship upon any community, manufacturing concern, or other civil activity." In asking the American Medical Association to assist in this double task, Surgeon-General Gorgas records his appreciation of the valuable help which it has already rendered to the War Department. The association has prepared a survey of the response already made by the medical profession of the United States to the call for volunteers for military service. It is interesting in this connexion to note the present position in Germany. According to a recent statement made in the Reichstag, more than two-thirds of the German medical profession are now serving in the army, with the natural result that many civilian districts in Germany are suffering from a serious shortage of doctors.

THE CAUSATION OF INDUSTRIAL ACCIDENTS.

A VALUABLE report¹ by Dr. H. M. Vernon to the Health of Munition Workers Committee on the factors concerned in the causation of industrial accidents is based upon his analysis of some 50,000 accidents which occurred at four large munition factories. At one factory the data were tabulated for 25½ consecutive months, at the other three factories the data were tabulated for 9½ to 13 months. At each munition works both men and women were employed. The special feature of this investigation, wherein it differs from previous inquiries, is that the accident data are correlated with the corresponding output data. Of the factors concerned in accident causation Dr. Vernon regards speed of production as by far the most important. The main personal factors are fatigue, psychological influences, nutrition, and alcohol consumption. Factors depending upon external conditions not directly under the worker's control include

¹Health of Munition Workers Committee, Memorandum No. 21. H.M. Stationery Office. Price 6d. net.

lighting, temperature, humidity and ventilation, defects of machinery, and absence of guards. Comparison of the hourly variations of accidents and output shows that during the day shift the accident curve corresponds qualitatively with the output curve; but the night-shift accidents attain their maximum at the beginning of the shift, and dwindle more or less steadily the whole night through, although the night-shift output curves for all but the last quarter closely resemble the day-shift output curves. The causes of this discrepancy between the accident and output curves of the night shift are mainly psychological. It appears that both men and women are much more prone to attend at the dressing station in the first part of the night shift than in the last part, but beyond this there is the more important factor of mental equilibrium. The day workers come to the factory in a sleepy state, but brighten up as the day goes on and the prospect of rest and enjoyment grows nearer. The night workers, on the other hand, have had their fun before coming to work, and so they start work in an excited state, which tends to produce carelessness and lack of attention, but calm down as the night wears on, since they have nothing but breakfast and bed to look forward to. The increase of accidents observed during the course of the morning spell is due partly to increasing speed of production, partly to increasing inattention arising from thoughts of pleasure to come, and partly, in women, to fatigue. Dr. Vernon explains how in lathe work a speeding up of 10 per cent. may well induce an increase of 50 or 100 per cent. in the number of accidents; a given speeding up of output means a relatively much greater speeding up of the movements made at moments when the workers are specially liable to knock their hands against cutting tools. The women were very much more fatigued by long hours than the men, and this fatigue predisposed to accident; in one factory a twelve-hour day increased the accidents among women two and a half fold, whilst it had little or no effect on the men. Dr. Vernon believes that if the factors of speed of production, alcohol consumption, illumination, and temperature could be equalized in the day and night shifts, the night accidents would be even fewer than those recorded—probably not more than two-thirds to three-quarters as numerous as the day accidents; and he is satisfied that this great difference is due to the psychological factor, the mind of the day worker being much more occupied with thoughts of matters unconnected with the work in hand. Cold tends to numb the fingers and blunt manual dexterity, and so increases the frequency of accidents. In one factory the women suffered nearly two and a half times as many accidents on the coldest days as on the warmest; the men were slightly less susceptible, but even they had more than twice as many accidents. At another factory which was better warmed there was no detectable seasonal change in the number of accidents. In order to reduce accidents to a minimum the temperature should be kept between 65° and 69° F.; as the thermometer falls below 50° accidents increase very rapidly. The problem of the causation of industrial accidents is extremely complicated, and Dr. Vernon points out that it can never be solved completely, since it is impossible to obtain data controlled by only one of the numerous factors; all are exerting their influence in greater or less degree, and it is only by a differential method that useful conclusions can be reached. Many industrial accidents—probably most—are unavoidable, and at best one can only hope to reduce their number. Moreover, any improvement of factory conditions which increases speed of production tends to an even greater increase of accidents. But if in all workers throughout their hours of labour the same mental outlook could be induced as is present in the night-shift workers during the early morning hours, the proportion of accidents due to carelessness and inattention would be greatly reduced. As a step in this direction Dr. Vernon recommends that all conversation should be

stopped, except that relating to the work in hand. Plugging the ears, if the workers would consent to do it, would shut out the distracting din of machinery, and, where practicable, lathes or other machines might well be separated by partitions. Excessive fatigue can be avoided by choosing suitable hours of labour.

AUTO-AGGLUTINATION OF RED BLOOD CORPUSCLES.

A DETAILED investigation of a case in which the blood serum contained an auto-agglutinin for the red blood corpuscles has been made by Clough and Richter¹ at the Johns Hopkins Hospital. Agglutination of a human being's red blood corpuscles by his own serum is so rare that some authors deny its occurrence. It has been described in hypertrophic cirrhosis of the liver by A. Klein and Reitmann, and by Landsteiner in horses and other animals. The auto-agglutination was probably independent of the disease (bronchopneumonia and auricular fibrillation) for which the patient came under observation, as it was present in a slighter degree in her daughter, and therefore may be regarded as a hereditary phenomenon. As the red blood cells when washed free from serum did not tend to agglutinate, the serum was solely responsible for the process, which occurred only at temperatures below 22° C.; the agglutination broke up at the body temperature. This auto-agglutinin was quite distinct from the ordinary iso-agglutinins, which act at the normal body temperature, since either could be adsorbed from the blood serum, leaving the other intact. An attempt to determine the chemical nature of the auto-agglutinin was inconclusive; by liberating the agglutinin from the washed red agglutinated red cell stroma a solution of agglutinin was obtained which gave a negative result with Heller's test and no precipitate with ammonium sulphate, thus showing that the solution contained less protein than in a 1 in 2,000 dilution of horse serum. The blood serum of the patient did not show any auto-haemolysin. Ascoli, who reported several cases of auto-agglutination, appears to have confused this phenomenon with rouleaux formation, and, in order to distinguish the two conditions more clearly, Clough and Richter made a similar study, not yet complete, of rouleaux formation. They found that the substance causing rouleaux formation resembled the auto-agglutinin in that it also was active on cells from other individuals, was precipitated from the serum with englobulin, and was not dialyzable; but differed in being active in concentrated serum only, in the rapid disappearance of its activity on standing, in causing rouleaux formation both at high and at low temperatures—its activity being increased by heating the serum to 65° C., and in not being adsorbed from the cells in the process of rouleaux formation.

CUTANEOUS AND FAUCIAL MANIFESTATIONS IN ACUTE POLIOMYELITIS.

As the onset and systemic stage of acute poliomyelitis may suggest the diagnosis of one of the exanthemata, such as scarlet fever or measles, attention should be paid to Dr. J. C. Regan's report² on the tongue, mouth, throat, and skin manifestations, about which comparatively little has appeared in the recent literature on the disease. His conclusions are based on observation of over 800 cases during the acute stage. The pharyngeal and faucial mucous membrane is almost constantly congested in the early stages, the soft palate being diffusely dark red in colour, while the hard palate is unchanged. Anaemia of the throat in the acute stage is very rare, and is almost confined to bulbar cases with a hopeless prognosis. The punctiform rash common on the soft palate in scarlet fever is not present in acute poliomyelitis, and the throat of

¹ *Bull. Johns Hopkins Hosp.*, Baltimore, 1918, xxix, 86-93.

² Reprint Series, No. 69. Department of Health of the City of New York, February, 1918, pp. 17. Reprinted from *Arch. Pediatrics*, December, 1917.

measles and of diphtheria after the membrane has disappeared is much more like that of poliomyelitis than is the throat of scarlet fever. Mild inflammation with some enlargement of the tonsils is very common, but follicular exudation and true membrane do not occur. In five cases the oral mucous membrane showed appearances like Koplik's spots. In bulbar cases there may be conjunctivitis. In the early stages the tongue almost always shows a moist greyish or yellowish-white coating, the tip and edges being free and redder than normal; after removal of the fur the papillae are not prominent as in scarlet fever. The coating is often "geographical" in its distribution. The lingual appearances in acute poliomyelitis and cerebrospinal fever are much alike as regards the thick yellowish-white covering over the anterior and middle parts of the dorsum. Gingivitis occurs in 10 per cent. of the cases, and is not so common or so well marked as in measles. Rashes are so frequent that they should be regarded as among the possible signs rather than as accidents, and among 1,017 cases were noted in 114, or 10 per cent. The same patient may have two rashes, one during the first or second week and the other during convalescence; 80 per cent. of the rashes occur in children under 3 years of age, and over 80 per cent. were observed during the first week. The mortality appeared to be lower in the cases with rashes than in those without. The average duration of the rashes, which may appear as early as the second day or as late as the sixth week, is about four days. In 90 per cent. the neck and chest were the site of the rash, and the extremities, especially the lower, were the parts least often affected; this distribution is obviously of value in the diagnosis of a scarlatiniform eruption from true scarlet fever. Bulbar cases rarely had an eruption, whereas meningitic cases very frequently presented this sign. The commonest rash is a pin-head papular eruption, which is generally preceded by a scarlatiniform eruption lasting from twelve to twenty-four hours. When occurring during convalescence a scarlatiniform rash, especially if the throat remains congested, is often difficult to diagnose from true scarlet fever, but the other symptoms are negative, and desquamation does not occur on the palms and soles. Many of these rashes are ascribed to intestinal toxæmia or to sweating, and the pin-head papular rash closely resembles, if it is not identical with, miliaria papulosa. Though herpes does not occur, large blebs may form on the skin. Desquamation, though rarely described in connexion with poliomyelitis, may be very frequent and profuse, usually furfuraceous and resembling that of measles, but sometimes suggesting scarlet fever; its distribution corresponds to that of the rash.

SERUM DISEASE.

THERE is a striking difference between the way in which animals and human beings react to a first injection of a foreign protein; in experimental animals the primary sensitizing injection is not followed by the train of symptoms so frequently seen in the serum disease of man. Anaphylaxis in man has naturally not been investigated to the same extent as in animals, and hence a recent research by Longcope and Rackemann¹ into the relation of the circulating antibodies to serum disease in twenty-five individuals who had received various quantities of antitoxic or antibactericidal horse serum is of interest. In order to determine the time of appearance and relation to serum disease of the circulating antibodies to horse serum observations were made at short intervals before, during, and after serum disease in the twenty-five cases by three methods—the precipitin test for horse serum, the demonstration of anaphylactin by the passive transmission of anaphylaxis to guinea-pigs by the injection of the patient's serum, and the production of a specific skin reaction by the intradermal injection of a minute dose of horse serum.

The conclusions from these observations are to the effect that serum disease is due to a reaction taking place in the cells of the body, and probably depends on the formation of a poison in the cells; that antibodies appear in the blood at first slowly and later rapidly after the occurrence of serum disease, their extrusion into the circulation being probably the result and not the cause of the serum disease; and that their presence in the blood serves to neutralize or destroy the antigen, and is a purely protective mechanism determining recovery from these manifestations. During the incubation period of serum disease there are no antibodies in the blood which contains a constant amount of the antigen (horse serum); but antibodies are forming in the cells, and when an explosive union between them and the antigen in the blood serum occurs the manifestations of serum disease appear, and their course depends on the amounts of antibody and antigen; thus, if the amount of horse serum originally injected is large and the antibodies slowly formed and deficient in amount, the antigen will persist and the manifestations of serum disease will be severe, prolonged, and relapsing. Whereas when the amount of horse serum originally injected is small and the antibodies formed in large amount it is probable that the antigen in the circulation will be soon removed and the serum disease mild and short. This reasoning corresponds with the general clinical experience that the severity of the serum rashes and other manifestations is in relation to the amount of serum injected. As regards the specific skin reaction it was shown that sooner or later this always follows injections of horse serum, whether in small or large doses, and that, unlike the presence of precipitin and anaphylactin in the blood, it is not dependent on the occurrence of serum disease.

THE LISTER INSTITUTE.

THE twenty-fourth annual report of the governing body of the Lister Institute shows that, as in previous years, energies have been almost entirely devoted to investigations bearing on problems arising out of the war and to routine war work. As we announced some time ago, experiments made by the Trench Fever Committee have shown that the accusation against the body louse that it is the agent guilty of transmission was well founded; the infection would appear to be derived not from the bite but from the excreta or crushed body of the louse, which becomes capable of conveying infection only about twelve days after being itself infected. Trench fever is, from the man power point of view, an important disease, and the discovery that the louse is one, if not the main, means of its spread, may lead to its eradication. This lends additional importance to the inquiries now being made on the best method of ridding soldiers of lice in the field, which are being carried on by Mr. Bacot in the Entomological Department of the Institute. The committee consists of Major-General Sir David Bruce (chairman), Dr. J. A. Arkwright, Mr. A. W. Bacot, Major W. Byam, R.A.M.C., Sir Walter Fletcher, K.B.E., F.R.S., Lieut.-Colonel H. French, M.D., R.A.M.C., and Lieut.-Colonel D. Harvey, C.M.G., R.A.M.C. The expenses of the inquiry have been borne by the Lister Institute. In its Bacteriological Department investigations have been continued into the prophylactic uses of dysentery vaccines and the serological classification of organisms of the supestifer group. In the Biochemical Department an investigation has been carried out for the Food Production Committee on the use of yeast foods in baking. Experiments on scurvy and beri-beri have been continued in this department, and in the director's department, under the direction of Miss Chick. The War Office committee on the study of tetanus, under the chairmanship of Sir David Bruce, has continued its work and Professor Sherrington, at Oxford, has made further investigations on the action of antitetanic serum in arresting tetanus in experimental monkeys. One result of Captain Tulloch's

¹ W. T. Longcope and F. M. Rackemann, *Journ. Exper. Med.*, Baltimore, 1918, xxvii, 341-358.

work at the Institute has been to show that at least three groups of organisms, differing from each other in their serological reactions, are included in the general designation *B. tetani*. The bearing of these observations upon the prophylaxis and therapeutics of the disease is at present a matter of inquiry, and the same worker has recently made observations on the part played by concomitant infection with anaërobic organisms other than *B. tetani* in the causation of tetanus, which it is hoped shortly to publish. Miss Robertson, as a result of the examination of 272 septic wounds, has shown the presence in many of a non-pathogenic organism morphologically indistinguishable from *B. tetani*, but differing in cultural and serological reactions. The routine work of the institution has been chiefly concerned with the preparation of vaccines and serums. The quantity produced at Elstree under the direction of Dr. MacConkey, assisted by Miss Houser, was prodigious, and included over 86,000 doses of tetanus antitoxin, nearly 58,000 doses of antidysentery serum, and over 150,000 of bacterial vaccines. At the request of the War Office, antimeningococcus serum has been put up in separate phials containing serums prepared from Types I, II, III, and IV of the meningococcus, and a large quantity of the various types have been supplied, as also of the four types mixed, for use where diagnosis is not clear. During the year the biochemical staff and the applied physiology staff of the Medical Research Committee have occupied several laboratories in the Institute, and accommodation has also been placed at the disposal of the Canadian and Australian Army Medical Corps, and of the cerebro-spinal meningitis laboratory of the War Office. As in the previous year, many members of the staff have been engaged in special war work either at the front or in military hospitals at home, but the large volume of work accomplished shows the zeal of the workers who remain and the excellence of the general arrangements carried out by Professor A. Harden, who is acting as director in the absence of Lieut.-Colonel C. J. Martin, and the stimulus of the influence of Major-General Sir David Bruce, who has acted as chairman in the absence of Major-General Sir John Rose Bradford.

MORBIDITY IN ART.

DR. T. B. HYSLOP'S oration before the Medical Society of London, on May 13th, dealt with some of the medico-psychological aspects of modern art, medicine, literature, and science. In the absence of the orator through illness, the president, Sir StClair Thomson, spoke the lines with becoming point and humour. In explanation of the vogue of morbidity in pictorial art as displayed by certain modern schools of painting, Dr. Hyslop quoted the opinion of Heine, that however mad a man may be he will always find somebody madder to admire him. From his study of the artistic efforts of the mentally unsound at Bethlem and elsewhere he concluded that art in asylums is just as honest and may be as pleasing as that exhibited for public gain. But he appeared to draw a necessary distinction between insane art and works of art which are not insane though produced by insane artists. We must not forget that while there are medico-legal tests for determining whether an individual—artist or artisan—is or is not of unsound mind, there are no fixed standards wherewith to estimate the sanity or otherwise of a work of art. The two things are in quite different planes. The physician is a good judge of sanity in an artist, but he is out of his depth when he presumes to appraise the sanity of a nocturne by Whistler, a statue by Rodin, or even of a neocubistic sunset. It is said that many great painters, sculptors, and engravers have suffered from nervous or mental disorders, or have shown distinct signs of degeneracy, though little trace can be found of this in their work. Great musicians, too, in common with other geniuses, seem to have been prone to madness, but here also it is well to bear in mind the

difference between degeneracy in the artist and degeneracy in art: one is a question of fact, the other a question of taste. Dr. Hyslop's discourse bore witness throughout to his many-sided tastes and accomplishments, and was followed with keen interest by a large audience.

MIDWIVES BOARD FOR IRELAND.

IN view of the fact that the profession in Ireland will shortly be asked to elect four representatives on the Central Midwives Board for Ireland, which is about to be formed, the Irish Midwives Act Committee held a meeting on May 14th at the Royal College of Surgeons, Dublin, and decided to put before the profession the names of the following four gentlemen as candidates for election: Sir Andrew Horne (chairman of the Committee), Dublin; Sir William Smyly, Dublin; Sir John Byers, Belfast; Professor Corby, Cork. The recommendation of this committee will undoubtedly have great weight with the electors when they are called upon to exercise their choice.

As will be seen from a detailed note in the course of a report of the last meeting of the Council of the Royal College of Surgeons of England, published elsewhere, it is proposed to place on a separate list the names of all Members admitted before the year 1870 whose addresses cannot be ascertained. This separate list will not be published in the *Calendar* for next year, 1918-19. At present the number on this separate list is a little over 1,000. Any Member who thinks he may fall within this category—that is to say, who obtained the diploma before 1870 and has not recently communicated his address—and wishes his name to be retained in the *Calendar*, should at once communicate with the Secretary of the College.

Medical Notes in Parliament.

Seniority Roster for Territorial Medical Officers.—Mr. Macpherson informed Sir Francis Blake, on May 15th, that a general seniority list of officers of the Royal Army Medical Corps (Territorial Force) is now in existence, but its publication was dependent upon certain alterations in establishment which had not yet been finally approved. Promotion would be by selection from among senior officers who had been recommended by general officers commanding in chief and approved by the Army Council. There were, of course, separate lists for the several ranks. Sir F. Blake asked if Mr. Macpherson was aware that some of the officers had twenty to thirty years to their credit, and that some of them had been upwards of ten years in their present rank. Mr. Macpherson said he was aware of that, and he hoped that the answer he had given would remedy these hard cases.

Medical Students in the Royal Navy.—Mr. Watt inquired, on May 9th, as to the arrangements being made by the Admiralty for the return of medical students from active service to continue their studies, and whether communications had been received from the Scottish universities pointing out the urgency of speedy relief in view of the fact that the summer medical session began on April 24th. Mr. Pretymann replied that an order was issued in January last calling for report of the names of all officers and men (other than surgeon probationers) who had, as medical students, passed the first professional examination in chemistry, physics, and biology. On receipt of these reports the lists were scrutinized, and where such a course appeared desirable the officer or man was allowed to return to continue his studies. Certain probationers were allowed to be demobilized at the end of six months' service at home or twelve months abroad in order to complete their studies and qualify. Mr. Pretymann could not trace any communication from the Scottish university authorities with regard to speedy release. A number of officers and men had already been conditionally released, but some time must elapse before the replies from distant stations were received and dealt with.

Treatment of Shell Shock Cases.—Mr. Hodge announced, on May 13th, in reply to Sir Montague Barlow, that he had decided, upon the recommendation of his medical advisers, to discontinue the use of the institution at Golders Green, which was within the zone of anti-aircraft gun fire, as a home for the treatment of shell shock and neurasthenia. Accommodation in a rural district, admirably suited for the treatment of these cases, had been procured at some distance from London. On

another question, by Sir William Collins, Mr. Hodge said that the reports received of the treatment of neurasthenic patients at this institution were satisfactory; but he had decided, on the recommendation of his medical advisers, that patients suffering from these diseases should be removed as far as possible from anti-aircraft gun fire. Fifty per cent. of the cases that were offered accommodation at Golders Green had declined to enter the institution. Many of the reasons alleged were on account of the fear of air raids, and a large number of the beds available were not in use.

Ozone Treatment of "Gassed" Soldiers.—In reply to Sir George Greenwood, who asked a question as to ozone treatment for "gassed" patients, Mr. Macpherson said that he assumed the inquiry had reference to the "Quain" ozone producer. He was informed that a description of this was forwarded to the Chemical Warfare Medical Committee in February last. The committee duly considered the matter, and reported that they were of opinion that it would be highly injurious to employ ozone in the treatment of "gassed" cases. The committee felt justified in forming this opinion without any further investigation.

Inoculation against Typhoid.—Sir A. Black asked, on May 14th, whether soldiers were now inoculated with a vaccine to protect against typhoid fever and paratyphoid A and paratyphoid B; how many doses were administered; and how often it was repeated. Mr. Macpherson replied that two doses of the vaccine were administered, the second being given after an interval of ten days. Soldiers were reinoculated yearly.

Pension Rights of Reinstated Officers.—Sir William Collins asked whether an officer who was reinstated after relinquishing a commission owing to wounds thereby permanently voided any accrued pension rights. Mr. Hodge said the matter was under consideration, and he hoped shortly to announce the decision.

Disablement Benefit.—Mr. Denniss asked, on May 14th, what arrangements had been made for the discontinuance of disablement benefit when a person reached 70 years of age and the full old age pension could be substituted in accordance with the original intention. Sir Edwin Cornwall replied that the administration of old age pensions did not fall within the province of the Insurance Commissioners, but it did not necessarily follow that a person in receipt of disablement benefit under the Insurance Acts was entitled at the age of 70 to a full old age pension. The usual statutory condition applied in each case.

Joint Insurance Committee.—Sir Edwin Cornwall stated, in reply to Mr. Booth on May 14th, that the Insurance Joint Committee meets as frequently as the business to be dealt with by it required. Mrs. Creighton was the only woman appointed. She resigned in November, 1913, and no other woman member had been appointed. The representatives of Scotland, Ireland, and Wales, who were the chairmen of the respective Commissions, were invited to attend all meetings of the committee, and were almost invariably present.

THE RECENT EPIDEMIC OF OBSCURE ORIGIN.

The following notes on cases of an obscure disease with cerebral symptoms recently prevalent have been prepared by the Medical Department of the Local Government Board (May 15th, 1918).

During the last three months a number of cases have been recorded in the medical press, and have been notified informally to medical officers of health, the symptoms of which have been described as bearing some resemblance to those of botulism. These and other cases are being investigated by medical inspectors of the Local Government Board and medical officers of health in collaboration with medical practitioners, but it seems advisable at this stage of the inquiry to summarize such records as are at present available.

Incidence.

The earliest case is reported to have had its onset on January 26th, and there were two having onset in the week beginning February 10th, and two in the last week of that month. In consecutive weeks in March, 7, 3, 10, and 14 cases came to notice, and in April and the first week of May the corresponding numbers were 11, 19, 14, 16, and 6.

The largest number of cases have been recorded in London, but groups of cases have occurred also in Sheffield and Birmingham, and single cases (and in one town 3 cases) have been notified from many other parts of England and Wales. The cases occurred among persons having the most varied occupations. No group of cases was associated with a single occupation. In only one instance were there two cases in the same household, and in this instance the second case was very mild and not admitted to hospital. The cases reported occurred about equally in the two sexes.

Although it is assumed that all the reported cases are

of the same disease, this cannot be regarded as certain. Already there is evidence from the *post-mortem* room that some of the cases are more ordinary disease.

The case mortality among cases regarded as belonging to the outbreak has approached 20 per cent. It is probable that slight cases have been overlooked.

The following table gives the approximate age incidence of 105 cases as compared with that of 2,559 cases of poliomyelitis notified in recent years in England and Wales.

Age.	Poliomyelitis.	Present Outbreak.
Under 10	88.2	14.3
10-20	8.3	24.8
20-30	2.0	15.2
Over 30	1.5	45.7
	100.0	100.0

Three cases occurred in infants in the first year of life, one of them (reported by Drs. Batten and Still in the *Lancet* of May 4th) being in a breast-fed infant aged 3½ months. Five were in children aged 1 to 5, and seven in children aged 5 to 10. Of 105 cases of which partial reports are available, 64 occurred in persons over 20 years of age.

Symptoms and Signs.

The clinical records at present available relate to 87 cases, but many of them are incomplete, and it is not certain that in all cases there was paralysis of cranial nerves. Using the terminology adopted by the different observers, the chief symptoms and signs recorded may be summarized as follows:

Among general symptoms pyrexia was recorded as being present in 41 of the 87 cases, usually in the early stage of the illness. It may have been present in some other cases which were not reported on while in that stage. In 8 cases it was stated that there was no fever. Of other general symptoms headache, or localized occipital, temporal, or frontal pain, was recorded in 31 cases. Profuse sweating was noted in 7 cases, and the presence of erythematous or other rash in 6.

Various mental symptoms come next to pyrexia in order of frequency—namely, drowsiness in 29 cases, lethargy in 18, stupor in 13, asthenia in 12, coma in 9; also vertigo in 17 and delirium in 20. Absence of lethargy was recorded in 3 cases and the presence of restlessness, or, irritability, or sleeplessness in 5.

Of symptoms referable to partial or complete paralysis of certain cranial nerves there were recorded bilateral facial paralysis in 9, unilateral in 11; bilateral ptosis in 32 cases, unilateral in 2; ophthalmoplegia in 18, diplopia in 18, strabismus in 10, nystagmus in 9, double third nerve palsy in 6, pupillary dilatation with failure of accommodation in 2, paralysis of the tongue in 2; affections of speech were noted in 5 cases. Rigidity of the muscles was recorded in 10 cases, muscular tremors in 9, and twitching or jerking of certain muscles of the face or limbs in 6.

Among symptoms referable to the gastro-intestinal system obstinate constipation was recorded in 35 cases, vomiting in 10 cases, difficulty of swallowing in 9, and dryness or soreness of the throat in 3. The parotid glands were swollen in 2 cases. Retention of urine was recorded in 15 cases, incontinence in 3. The records relating to the circulatory and respiratory systems are not sufficiently complete for useful summary at present.

Relationship to Food.

Although in a considerable proportion of the reported cases there was a history of the recent consumption of such foods as sausages, sardines, shrimps, lobster, tinned salmon, cheese, bacon, and ham, these and other exceptional foods had not been consumed in the majority of reported cases; and no particular food has been found to be related to the outbreak.

The pathological investigation of the outbreak is being undertaken by the Medical Research Committee. The results so far obtained show no bacteriological evidence of botulism, and give no support to the association of the outbreak with infection from food. Further investigations are in progress.

THE WAR.

MILITARY CONVALESCENT HOSPITALS.

WE are indebted to Major George Lane, R.A.M.C., S.R., for the following extracts from an article on the organization and general working of convalescent camp hospitals:

In July, 1916, I was appointed Commandant of the convalescent camp hospitals at —. I soon arrived at the conclusion that thorough drainage would make the site all that could be desired even in the wettest seasons. The whole system of drainage, road-making, bridging, and levelling of this camp (of over 5,000) was done by the convalescents themselves, under the direction of myself and my officers. The work took nearly twelve months to complete.

Site.

The site of a convalescent camp should be naturally well drained, or admitting, without great labour, of an easy drainage system. It should also be fairly sheltered. For troops recovering from wounds and debilitating illnesses a dry camp is essential. In laying out the camp the possibility of expansion up to six or even ten thousand should be borne in mind.

The position of the camp with regard to railway facilities is very important, as the means of receiving and evacuating the convalescents, and of transport generally, must be considered. There are evident advantages in selecting a site, otherwise suitable, near a great town. There should be ample ground, if possible, for cultivation. In the hospital I commanded I had a vegetable garden for each camp, and planted besides some ten acres of potatoes.

Water, Kitchens, and Stores.

The water supply is of great importance, especially abroad. This must be plentiful and of good quality. There ought to be abundant water for baths, hot and cold, at all times. In addition to the sprays there should be a certain number of fixed immersion baths.

In consultation with the engineer officer and the sanitary adviser proper sites should be chosen for the mess tents (or huts), cookhouses, stores, latrines, etc., for each camp or division, the endeavour being to make each camp a self-contained unit and, as far as means admit, self-supporting. The cookhouses would consist of the usual wooden structures, with cement floors, and fitted with large stoves, supplemented by Soyer's stoves outside.

In consultation with the quartermaster special accommodation should be chosen in a central position for all the stores and equipment of the camp. There should be one quartermaster to each camp or division of 1,000.

Cot Hospital.

The cot hospital should consist of three or four special huts with accommodation for 100 cases. This building requires a small dispensary, kitchen, pantry, pack store, and bathroom, and proper means of heating in winter. The personnel is drawn from the R.A.M.C. Cases of slight relapse or minor illness are quite justifiably treated here, but if the patient's illness is obviously serious or likely to be prolonged, he should be sent to a hospital.

Accommodation on a fairly liberal scale is required for the dental department, which should be near the cot hospital. In my camp there were four dentists, with many mechanics and assistants.

Canteens and Messes.

Dry and wet canteens should be provided in a fairly central position. Convalescent officers, if the camp accommodates them, should, I think, mess separately in their own mess. Sergeants' messes should be arranged for.

Staff.

The staff at head quarters will consist of the commandant, two adjutants, paymaster, camp quartermaster, sanitary officer, and a camp sergeant-major, chief clerk, and other clerks drawn from the convalescents.

Each camp should have a somewhat similar staff on a smaller scale. As these are hospitals, the officer in charge of a camp or division should be a medical man with a bent for administrative work. Dealing with convalescents requires technical knowledge not possessed by, nor to be acquired by, combatant officers. For a thousand men an assistant M.O. is desirable, as classifying men into their proper categories requires great care. The officer in charge of each camp should have detailed for duty under him a combatant officer of some experience. Convalescent officers

are usually very glad of interesting light work, which, by the way, is beneficial for them.

In the camps commanded by me all our work was done by convalescents—cooks, nursing orderlies, mess orderlies, and so forth. By this means the men were kept employed and happy, and great economy was effected. As they became fit they were sent off, and their places were filled by succeeding convalescents. But a skeleton permanent staff is essential for the efficient management of a large camp.

Workshops.

My first duty being to get the men fit, I carefully supervised the kitchens and the feeding of the men. Suppers were contrived out of the dinner savings and were greatly appreciated. The food was good and was not spoilt by bad cooks. The men were, by graduated steps, brought to a high state of physical efficiency, and were then passed on. I had a register kept by each medical officer in charge of a camp, wherein was recorded on admission every man's vocation in private life, so that the mistake was not made of putting a carpenter to do a blacksmith's job. Thus the men exercised themselves during convalescence at congenial work of a practical nature and of monetary value. This led me to establish workshops, at first in a small way. Later on, skilled masons and carpenters built, under the supervision of a convalescent engineer officer, a large stone-made workshop containing carpenter's shop, blacksmith's shop, painter's shop, tinsmith's shop, bootmaker and repairer's shop, tent repairer's shop, watchmaker and engraver's shop, tailor's shop, and piano-tuner's room. The materials used by the carpenters and tinsmiths were discarded packing cases and empty paraffin and petrol tins. When completed, the articles were sold at a nominal price. Books were kept showing the materials used and their ultimate disposal. The money received went for the benefit of the funds for the men. Much of the success that attended this venture was due to the help given me by the A.D.O.S., without whose aid I could not have got tools. No men were taught trades.

Each camp had its own barber's saloon, with a tent attached where the men could obtain the services of a skilled chiropodist and masseur. Shortly after my arrival I found difficulty in procuring fresh eggs and chickens, and decided to have my own poultry yard. Later I prevailed on the mess president of the officers' mess to do the same, with good results on strictly business lines.

Recreations.

If the men have plenty of healthy sports and amusements they will regard the camp as their temporary home. The first thing to provide is a good brass band, and if possible a bugle and fife band for route marches. There should be cricket and football clubs, a gymnasium, tennis courts, and, if near the sea coast, boating and swimming clubs. At Christmas in our camp some of the officers and men produced a pantomime, which afforded amusement to thousands of wounded and sick. All the scenery was painted in our workshops, and the costumes, etc., made by our own tailors.

Through the kindness of the British Red Cross Commissioner a motor lorry was available for the use of officers and men proceeding to football matches, etc. The Red Cross had tea and recreation rooms in the camp, and the Commissioner saw that the men were plentifully supplied with games, newspapers, reading and writing materials. The Y.M.C.A. representatives also were very keen in affording the men amusements and in supplying their wants. A cinema show is a great asset to a camp. For the officers I converted an old ordnance hut into a club. It was painted and done up by the men in the shops. I borrowed three full-sized billiard tables, and made the place very comfortable, with seats and card tables.

ARTERIAL CONTRACTILITY IN WOUNDS.

F. KROH and M. KRABBEL¹ have contributed papers on the general pathology of recent gunshot injuries of the circulatory organs. In illustration of the defensive value of the elasticity of the vessel walls a case is mentioned of clean perforation of the femoral artery by a grenade fragment having a diameter two and a half times greater than that of the vessel itself. That severe contusive effects could occur in the absence of any visible macroscopical lesion of the vessel walls was shown by such cases as the following: A bullet wound of the groin was followed by venous haemorrhage and loss of pulsation

¹ *Brunn's Kriegschirurg. Hefte*, 1917, Ixv, pp. 61 and 76.

in the femoral artery. The vein was found to be completely severed and the artery spasmodically contracted to the size of a knitting needle. While under observation the artery gradually resumed its normal dimensions, pulsation returned, and the limb became hyperaemic. As an example of thrombosis resulting from the pressure of a haematoma the case is cited of wound of a perforating artery of the thigh followed by extensive extravasation. The great vessels were found to be uninjured, but those portions of the femoral artery and vein which lay within the haematoma were thrombosed. Several examples were mentioned of wounds involving the two outer coats only of the artery, the intima being intact and forming a sacular bulging through the rent. Comment was made on the apparent relative infrequency of injury of the large vessels (apart from those leading to traumatic aneurysm) from bullets and shrapnel as compared with grenade wounds. It was suggested that many cases might escape detection where the wound healed without operation, since the haemorrhage might be insignificant in these cases. In examining a recent bullet wound of the arm in which haemorrhage had been slight, the brachial artery was found to be completely severed, and its wounded extremities were occluded by firm thrombi, which must have formed with extreme rapidity. Other similar cases are mentioned, and Kroh described a case of penetrating shrapnel wound of the right ventricle, where the wound was found to be perfectly occluded by a clot.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Prisoner of War.

Surgeon W. A. McKerrow, R.N.

ARMY.

Killed in Action.

MAJOR R. G. GORDON, D.S.O., R.G.A.

Major Reginald Glegg Gordon, D.S.O., R.G.A., killed on March 26th, during the recent retreat, whilst riding at the head of his battery, was born at Valparaiso on September 26th, 1878, the only son of Mr. D. S. R. Gordon. He was educated at the Edinburgh Academy and University, and graduated M.B., Ch.B., in 1903. He was a keen volunteer, footballer, and cricketer, and everything he took up he did thoroughly. After leaving the university he was appointed an assistant medical officer at the Crichton Institution, Dumfries, and later studied insanity in the asylums of Italy, but on the death of his father he gave up the practice of medicine and took to farming. When war broke out he lost no time in joining the colours, and was mentioned in dispatches last year, and received the D.S.O. in January, 1913. His colonel, in a tribute to Major Gordon's qualities as a soldier, writes: "He was a man we all liked and respected. During the trying time of the last few days he carried out his duties in an exemplary manner, with perfect courage, and was a standing example to all others." He leaves a widow and four young daughters.

CAPTAIN P. G. MILNE, R.A.M.C.

Captain Patrick George Milne, R.A.M.C., was reported as killed in action, in the casualty list published on May 10th. He was educated at Aberdeen University, where he graduated M.B. and Ch.B. in 1912, after which he took a temporary commission as lieutenant in the R.A.M.C., and was promoted to captain after a year's service.

CAPTAIN T. WHITELAW, R.A.M.C.(T.F.).

Captain Thomas Whitelaw, R.A.M.C.(T.F.), was reported as killed in action, in the casualty list published on May 13th. He was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1912, and took a commission as lieutenant in the 1st Northern (Newcastle) General Hospital on April 20th, 1915. He was attached to the Duke of Wellington's Regiment when killed.

Died of Wounds.

CAPTAIN J. F. MATHESON, M.C., R.A.M.C.

Captain James Frederick Matheson, M.C., R.A.M.C., was reported as having died of wounds, in the casualty list

published on May 9th. He held a temporary commission in the R.A.M.C., and received the Military Cross on January 1st, 1918.

CAPTAIN J. B. METCALFE, A.A.M.C.

Major J. B. Metcalfe, Australian Army Medical Corps, was reported as having died of wounds, in the casualty list published on May 10th.

CAPTAIN H. G. MASSY-MILES, R.A.M.C.

Captain H. G. Massy-Miles, R.A.M.C. (temporary), who was stated to have died on service, in the BRITISH MEDICAL JOURNAL (p. 545), was reported to have died of wounds, in the casualty list published on May 11th.

Died on Service.

MAJOR J. W. LITTLE, I.M.S.

Major John Wishart Little, I.M.S., died at Karachi on May 7th, aged 41. He was born on March 27th, 1877, the youngest son of the late Dr. Robert Little of Singapore, and was educated at St. Thomas's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1900, and graduating M.B.Lond., with honours in forensic medicine, the same year. Entering the I.M.S. as lieutenant on June 27th, 1901, he became captain on June 27th, 1904, and major on December 27th, 1912. He served on the North-West Frontier of India in the Waziristan campaign of 1901-2 (medal with clasp); and in East Africa, in Somaliland, in 1903-4 (medal with clasp). Before the war he was agency surgeon at Gilgit.

CAPTAIN MCQUIBAN, R.A.M.C.

Captain William McQuiban, R.A.M.C., died on service in Egypt on May 2nd. He was educated at Aberdeen University, where he graduated M.B. and Ch.B. in 1901. He was in practice at Lordship Park, Stoke Newington, till he took a temporary commission in the R.A.M.C.

Wounded.

Colonel J. W. H. Houghton, D.S.O., A.M.S.

Lieut.-Colonel W. R. Gardner, D.S.O., R.A.M.C.(T.F.).

Lieut.-Colonel J. la F. Lander, D.S.O., M.C., R.A.M.C. (temporary).

Lieut.-Colonel C. A. Stidston, D.S.O., R.A.M.C.(T.F.).

Major W. McM. Chesney, M.C., R.A.M.C.(S.R.).

Major L. S. C. Roche, M.C., R.A.M.C. (temporary).

Captain D. W. Anderson, R.A.M.C. (temporary).

Captain G. F. Carr, R.A.M.C.(T.F.).

Captain A. Fordyce, R.A.M.C.(T.F.).

Captain S. G. Gibson, M.C., Australian A.M.C.

Captain H. M. Godfrey, R.A.M.C. (temporary).

Captain W. S. Hawthorne, Australian A.M.C.

Captain J. I. Lawson, R.A.M.C.(S.R.).

Captain J. M. Mackay, M.C., R.A.M.C. (temporary).

Captain M. H. Muller, M.C., Australian A.M.C.

Captain R. W. Pearson, R.A.M.C. (temporary).

Captain J. McG. H. Reid, R.A.M.C. (temporary).

Captain A. B. Simes, Canadian A.M.C.

Captain J. M. Smith, R.A.M.C.(T.F.).

Captain J. Stevenson, R.A.M.C.(S.R.).

Captain J. E. G. Thomson, R.A.M.C. (temporary).

Captain T. D. C. Watt, M.C., R.A.M.C. (temporary).

Captain H. E. Williams, R.A.M.C. (temporary).

Captain H. Wilson, R.A.M.C.(T.F.).

Captain and Quartermaster J. T. Starkie, M.C., R.A.M.C.

Lieutenant J. B. Taylor, R.A.M.C. (temporary).

Missing.

Captain S. S. Meighan, M.C., R.A.M.C.(T.F.).

Captain J. F. Natrass, R.A.M.C.(T.F.).

Captain F. C. Nichols, M.C., R.A.M.C.(T.F.).

Captain S. V. P. Pill, R.A.M.C. (temporary).

Lieutenant D. Robertson, R.A.M.C. (temporary).

Prisoners of War.

Captain D. F. Debson, R.A.M.C. (temporary).

Captain R. R. Duncan, R.A.M.C. (temporary).

Captain J. G. Elder, R.A.M.C. (temporary).

Captain L. S. H. Glanville, R.A.M.C. (temporary).

Captain D. C. Hanson, M.C., R.A.M.C. (temporary).

Captain H. B. Jones, R.A.M.C. (temporary).

Captain C. E. Redman, R.A.M.C. (temporary).
 Captain F. P. Smith, R.A.M.C. (temporary).
 Captain J. P. Thierens, R.A.M.C. (temporary).
 Captain F. R. Tickle, R.A.M.C. (temporary).
 Lieutenant G. B. Berkley, M.C., R.A.M.C. (temporary).
 Lieutenant F. J. Power, M.C., R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

McBride, Andrew Best, Captain Bedfordshire Regiment, elder son of Major John Best McBride, R.A.M.C. (T.F.), of Berkhamsted, died of wounds on April 24th, aged 22. He was born on June 16th, 1895, and educated at Berkhamsted School and at King's College Hospital, London, where he had passed the first professional examination in medicine of London University. He got his commission in the Bedfordshire Regiment as lieutenant on September 28th, 1914, and was promoted to captain on June 1st, 1916.

Rice, Edmund Gabriel, Lieutenant R.A.F., killed in a flying accident at Redcar, Yorks. on May 3rd. He was the only son of Dr. C. E. Rice of Coventry, and was just under 19 years of age. He was educated at Wolverhampton Grammar School and at Bedale School. He became a probationary flight officer in the R.N.A.S. in June, 1917, and was sent to the front in France in December, where he was on active service as an aerial scout until the end of March, when he was invalided home after fainting at a height of 18,000 ft., fortunately recovering at a height of 4,000 ft. in time to avert disaster. He was subsequently appointed instructor. The funeral took place at Coventry on May 8th with full military honours.

Ruxton, William Stewart Mitchell, M.C., Lieutenant Border Regiment, only son of Dr. Ruxton of Newcastle-on-Tyne, killed April 12th, aged 20. He was educated at Shrewsbury, where he was a sergeant in the O.T.C., entered Sandhurst in September, 1915, got his commission in January, 1916, went to the front in July, 1916, was wounded in September, returned to the front in January, 1917, got the Military Cross in September, 1917, and became acting captain in January, 1918.

St. Leger, Wm. Brett, M.C., Lieutenant Coldstream Guards, killed in action April 27th, aged 23, elder son of Major R. A. St. Leger, S.A.M.C., of George, South Africa, and grandson of the late Dr. Brett of Watford, Herts. He was educated at the South African College, Cape Town, and was a corporal in the Cape Town Highlanders when war broke out. He served with that regiment in German South-West Africa, and afterwards came to England and joined the O.T.C., eventually obtaining a commission in the Coldstream Guards. He proceeded to France in July, 1916, and was wounded in July, 1917. He was awarded the M.C. for conspicuous gallantry on that and former occasions.

Stone, Noel Herbert, M.C., Captain Worcestershire Regiment, eldest son of Dr. H. S. Stone of Reigate, killed April 27th, aged 22. He got his first commission on December 16th, 1914.

Tate, Alan C. R., Lieutenant Royal Air Force, eldest son of Colonel Alan Tate, C.M.G., A.M.S., of Quetta, killed while flying on patrol on May 2nd. He was educated at Charterhouse and Stonyhurst, and had served for a year as an orderly under the French Ronge Croix before he entered the Royal Flying Corps as a cadet in June, 1917, passed as a pilot early in 1918, and went to the front in March.

Trevor-Jones, John Eric, M.C., Captain Rifle Brigade, second surviving son of Major E. J. Trevor-Cory, R.A.M.C., killed April 22nd. He was born in 1893, educated at Clare College, Cambridge, and got his commission on January 22nd, 1916. He went to France in July, 1916, and got the Military Cross in March, 1917.

Walker, John Binning, Canadian Reserve, only son of the late John Walker of Kingussie, died of pneumonia in No. 14 Canadian General Hospital, Eastbourne, on May 3rd.

Williams, R. M., Captain Royal Welsh Fusiliers, attached to the Royal Flying Corps, son of Dr. Richard Williams, formerly of Liverpool and now of Lleniog Castle, Anglesey, reported missing on August 12th, 1917, was, according to news received through the German Red Cross, killed on that date.

MEDICAL STUDENT.

Kennedy, Alexander, M.C., Captain Royal Scots, third son of Mr. Alexander Kennedy of Barnton, killed April 26th. He had completed his third year as a medical student when, at the beginning of the war, he enlisted in the Royal Scots. He was wounded while a sergeant, got a commission in 1917, and had rapidly risen to captain.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

The following awards in recognition of "conspicuous gallantry and devotion to duty" in the field are announced in a Supplement to the *London Gazette* of May 13th:

Military Cross.

Temporary Captain Henry Drummond Robb, R.A.M.C.

On his camp and its vicinity being heavily shelled he was compelled to conduct his sick parade along roads which were at the time under heavy shell fire. He succeeded in leading his wounded cases safely under cover, and later remained behind to attend to

the men of a neighbouring unit, which had also suffered some casualties as a result of the intense shelling. His courage and devotion to duty were of the highest order.

Temporary Captain Samuel Rutherford, R.A.M.C.

During a period of sixteen hours he tended the wounded in the front trenches without ceasing. Throughout this period he was exposed to heavy shell fire, and for some considerable time the enemy were within a short distance of the aid post. His coolness and presence of mind inspired all ranks with the utmost confidence.

Temporary Quartermaster and Honorary Lieutenant Robert Leslie Masters, R.A.M.C.

When a camp and some billets were heavily shelled by the enemy he at once went to the rescue of some men who had been buried in the ruins of a house, and rendered first aid. He then organized bearer parties from among his men, and brought in four severely wounded men from the camp. By his disregard of danger, quick decision, and good leadership he set a splendid example to his men, and rendered valuable assistance to the wounded in the absence of a medical officer.

In the *London Gazette* of May 11th, 1918, the names of Captain A. J. Evans, R.A.M.C. (T.F.) and temporary Captain A. T. Gibb, R.A.M.C., are added to the list of officers whose services have been brought to notice as deserving of special mention by the late Lieut.-General Sir Stanley Maude, K.C.B., Commander-in-Chief, Mesopotamian Expeditionary Force (*BRITISH MEDICAL JOURNAL*, August 25th, 1917, p. 268).

NOTES.

THE Inter-Allied Congress on the after-care of discharged sailors and soldiers, which is to be opened at the Central Hall, Westminster, on Whit Monday, May 20th, at 11.30 a.m., by the Duke of Connaught, will meet in four sections. The first—on pensions and allowances—will have Sir Arthur Griffith-Boscawen, M.P., Parliamentary Secretary to the Ministry of Pensions, as chairman, and he will open its proceedings by reading a paper on pensions and allowances. He will be followed by speakers on the same subject from France, Italy, and Belgium, and a general discussion will ensue. The second section—on training—to be presided over by Sir Charles Nicholson, Bt., M.P., will hear papers on the subject from representatives of Great Britain, France, United States of America, Italy, Canada, and South Africa, and after they have been debated a discussion on agricultural re-education will be introduced by a series of papers. The third section—concerned with the treatment of men suffering from nervous injuries or disorders, including blindness and deafness—will be presided over by Lord Charnwood. Papers on neurasthenia will be contributed by representatives of Great Britain, Italy, and Australia. A discussion on the care of the tuberculous soldier will be introduced by Major P. H. S. Hartley, C.V.O., R.A.M.C.; on the blind, by Sir Arthur Pearson, G.B.E.; and on the deaf by Dr. Dundas Grant. The fourth section—on surgical treatment—will discuss the treatment of limbless men, orthopaedics, and functional restoration and re-education of the wounded, the speakers including Sir Wm. Macewen, Sir Robert Jones, Majors Turner and Boyer, C.A.M.C., and Major Sandes, S.A.M.C.

Correspondence.

UNIVERSITY REPRESENTATION IN PARLIAMENT.

SIR,—I am not concerning myself with the political views of either Sir M. Abbot Anderson or Dr. Rowland Fothergill, but when the former states that all the graduates resident in London whose names and addresses could be found were invited to attend a meeting, I at least have my doubts as to the accuracy of that statement, or, to put it in another way, that any great pains were taken to find them.

Certainly at the present moment I am not actually resident in London, as in more peaceful times, but I am on the Council of the Graduates' Association of my university, and joint-secretary of the Metropolitan Counties Branch of the British Medical Association, and one would think, therefore, that both my name and an address could have been obtained fairly easily—even without reference to such a handy aid as the current edition of the *Medical Directory*—but I never received any invitation to the meeting, or even intimation that such was to take place.

I do not know on what date it was held, but it is probable that I was in England at the time, and if so it is certain that I should have endeavoured to be present—if only to hear what was going on.—I am, etc.,

B.E.F., France, May 10th.

WILFRED KINGDON.

SIR,—Captain Fothergill, in his letter on the above subject in your last week's issue, stated that "Belfast University is finding a medical candidate without looking to a party in politics for any assistance."

I regret to say that Captain Fothergill's facts are more misleading than fiction. Doubtless Sir W. Whitla's Parliamentary committee were able to find him without the aid of any political party organization, but they are looking to the party politics of the graduates to get him elected as their member. In the official appeal for support the secretaries of his committee begin by saying, "Sir William is a staunch Unionist and a trusted representative of Ulster on the Irish Convention, where during nine months of strenuous labour he has enjoyed the fullest confidence of his colleagues. He is, moreover, a brilliant member of his profession, . . ."—that is, party politics first, medical claims a poor second; unless, indeed, his services at the Convention during its labour, prolonged for a period equal to that of a normal gestation, were of a professional character! (The dismembered condition of the fetus on delivery is notorious, and reflects little credit on the accoucheur!)

The philosophic doubt of Mr. Balfour finds no place in the psychology of present-day Ulster, and should my old teacher be returned as member for the Belfast University, and should the supposed interests of the medical profession ever clash with the supposed interests of the North-East of Ireland, there is no uncertainty as to the lobby into which his political tail will waggle the professional trunk of Sir William Whitla.

Captain Fothergill's idea of non-political representation for our universities is, I fear, Utopian.—I am, etc.,

Old Basford, Notts, May 14th.

ADAM FULTON.

THE VALUE OF AMYL NITRITE INHALATIONS IN THE DIAGNOSIS OF MITRAL STENOSIS.

SIR,—The suggestion made by Dr. Morison (p. 452) that the murmur indicative of the presence of mitral stenosis can be made more evident by causing the patient to inhale amyl nitrite is open to more than one fallacy.

The abnormal sound which is very commonly mistaken for the presystolic murmur of mitral stenosis is the diastolic sound, sometimes called part of a reduplicated first sound, sometimes part of a reduplicated second sound audible at the apex, sometimes a mid-diastolic sound, or even the third sound of the heart, and it is probable that this sound, when present, would be made more distinct by the inhalation of amyl nitrite.

It is strange how very few even of well-qualified medical men of considerable experience are aware of the danger of mistaking the sound in question for a true presystolic murmur, in other words, of the danger of considering it to indicate the presence of mitral stenosis.

Although a sound of this character may be heard over a healthy heart in a healthy person, it is more likely to occur in a person with a low vasomotor tone—that is, one in whom the neuro-muscular system of the circulation does not react quickly to the various demands which the movements of the body make upon it. A similar low vasomotor tone is produced by the inhalation of amyl nitrite, and it appears probable that the drug would accentuate a sound which is no indication of disease.

I do not suggest that amyl nitrite may not also render more distinct the true murmur of mitral stenosis. The murmur present in mitral stenosis is, however, one the method of production of which is not evident. Its causation is not, I believe, so simple as Dr. Morison seems to think. The morbid anatomy of mitral stenosis presents other serious changes besides mere narrowing of the mitral orifice. For example, the chordae tendineae may be so shortened that they have disappeared and the large flap of the mitral valve is in contact with the apices of the muscular pillars. The action of the left ventricle must thus be hampered and great muscular strain must be brought to bear upon the thickened and shortened mitral flap. What effect has amyl nitrite upon the hampered ventricle, and how is that effect, whatever it may be, to influence the sound which occurs during the ventricle's contraction? I cannot make any suggestion. The trial of amyl nitrite may prove to be interesting, but it does not seem to me that it is likely to give reliable indications as to whether organic disease is present

or not. If it does, I should favour the view that amyl nitrite will influence the diastolic sound of a normal heart but not the presystolic murmur of mitral stenosis.—I am, etc.,

Norwich, April 25th.

THEODORE FISHER.

TONSILLECTOMY IN DIPHTHERIA CARRIERS.

SIR,—It seems to me that Captain Ballantyne and Lieutenant Cornell, C.A.M.C., in their paper on the report on tonsillectomy in diphtheria carriers (*BRITISH MEDICAL JOURNAL*, 1917, ii, p. 686), start with false premisses. One only of the six cases quoted—namely, the second—ought to be regarded as a carrier. The fifth case might also be admitted by some into this category. Cases 1, 3, and 4 were positive as to swabs for three weeks, nine days, and twelve days respectively before the operation. To classify a patient as a carrier of diphtheria bacilli because he has positive swabs for nine or twelve days is not justified, as it is a common experience in fever hospitals to find this and then to get negative cultures without gargles or throat applications of any kind whatever. Details of the dates of onset of the disease in the various cases cited are lacking, except in Case 6, a man admitted with diphtheria on June 5th; on June 29th (the twenty-fourth day after admission) a tonsillectomy was performed on him, on the ground that he was a diphtheria carrier. This does not seem to me to be sound, and if it is taken as a standard and acted upon, then there will be several hundreds in London alone every year who will have tonsillectomy performed on them as diphtheria carriers, while now, as a result of a little patience, they are discharged from hospital free from any infection.

There is another point to which I would like to draw attention. In these cases the authors were evidently satisfied that the patients were not harbouring the organism after the operation after swabs from the throat only. No mention is made of cultures from the nose. Now, before a diphtheria patient can be said to be free completely from the disease, separate cultures ought to be made from the throat and the nose. It is not uncommon after faucial diphtheria to get persistent negative cultures from the throat, and at the same time to get positive cultures from the nose. I am not confusing purely faucial diphtheria with purely nasal diphtheria when I say this. No mention is made either of a further course of diphtheria antitoxin for carriers. In practice the risk of anaphylaxis in diphtheria is almost negligible.

I was pleased to notice that 12,000 units of antitoxin were given in Case 6, "mild diphtheria," as there still seems to be some diffidence in giving comparatively large doses of antitoxin in diphtheria. In the North-Eastern Hospital it was our practice to give 12,000 to 16,000 units in a mild case, and up to 32,000 or 36,000 (rarely 40,000) units in very severe cases, with a repeated dose in twelve hours if the exudate was still spreading.—I am, etc.,

P. FIGDOR,

Captain R.A.M.C.

March 9th.

The Services.

INDIAN MEDICAL SERVICE.

AT a meeting of the Imperial Legislative Council of India on February 28th Mr. Sastri moved a resolution proposing that the technical and scientific services should be recruited entirely in India, and that an effort should be made to provide the requisite educational facilities in that country. After an assurance from the Government spokesman that the Viceroy and Secretary of State were endeavouring to give effect to the progressive realization of responsible government in India the resolution was withdrawn.

At the meeting on March 5th Mr. Sastri brought forward a resolution recommending:

- That a civil medical service should be constituted which should be wholly independent of the medical organization of the Indian army, that the higher medical posts which are at present filled by officers of the Indian Medical Service should be transferred to the civil medical service, and that the civil medical service should be recruited from the civil medical officers and the independent medical profession; (b) that the salaries of Indian Medical Service officers employed on civil duty should not be enhanced as recommended by the Public Services Commission; and (c) that military assistant surgeons should not be given preference over civil assistant surgeons, and that not more than one-sixth of the higher posts reserved for subordinate medical officers should be given to them.

He protested against the proposal of the Public Services Commission for an advance in the pay of the I.M.S., considering that the number of its members in civil employ shut out native talent and made the civil population dependent on a service which might be called upon to do military duty at any time. He did not share the apprehension that all the services in India would suffer in popularity if British officers and their wives had to resort to Indian doctors. As to the necessity of maintaining a war reserve, he said that he had ascertained from young Indians in the medical colleges that they would be quite willing to support any proposal the Government might make to impose on all officers in civil employ the obligation to undergo military training and to be liable for military service. The private medical profession in India had readily responded to the calls made upon it during the present war. The I.M.S. had done wonders for India, but should not be allowed to dominate the civil population and to keep the children of the soil out of what was rightly theirs.

Surgeon-General Edwards, who has succeeded the late Sir Pardey Lukis as Director-General I.M.S., in his reply, said that acceptance of the resolution would be tantamount to the abolition of the service, which had done work of the greatest value, not only to India, but to the world at large. He spoke of the work done with regard to the malaria parasite, to cholera, amoebic dysentery, prostatic surgery, and eye surgery; with regard to kala-azar and ankylostomiasis, to snake venom, and as to goitre. He then referred to the magnificent educational work done by the I.M.S., and added that if expert professors were to be specially engaged they must be offered much higher salaries and would not have the intimate knowledge of Eastern diseases which officers of the I.M.S. possessed. It must be remembered that very few I.M.S. officers made from £1,000 to £2,000 a year by private practice. Some 400 I.M.S. men held civil posts in India in peace, but a distinguished Indian medical man had informed the Bengal Legislative Council that over 30,000 doctors were required there. At present there were only 2,000 on the medical register, and of these some 40 were I.M.S. men. Could this small band be said to be standing in the way of the aspirations of Bengal practitioners? To cut India adrift from intimate medical contact with progressive Western countries, which would be the outcome of the resolution, would be a short-sighted policy. On the other hand, he was strongly in favour of a Provincial Civil Medical Service; such services existed, but they ought to be greatly enlarged, especially in their public health departments, and the old-fashioned name of "assistant surgeon" dispensed with and the hideous name "subassistant surgeon" forgotten. As the Indian Medical Service was the war reserve, appointments must be reserved for its members in the provincial medical services. That was practically what was now being done. If military medical officers were to be kept fully employed in peace, less than half their number would be amply sufficient to carry on routine military duties. It was asked why this was not done in the R.A.M.C. The answer was that it would be done if the British army in peace were stationed in England and if there existed a civil medical service into which its surplus officers could be drafted. But the British army was scattered all over the world; most of the R.A.M.C. officers would prefer to have more professional work in peace time. The Indian Medical Service had lately ceased to attract medical men of the highest attainments, either British or Indian; it must therefore be mended or euded, and he unhesitatingly maintained that in the interests of India it ought to be mended. If first-class men were required they must be sought in the open market and paid their market value, and he trusted that none but the best would be considered good enough for India. With regard to the third part of the resolution, military assistant surgeons would in future be required to take a qualification recognized in Great Britain. In conclusion, he said that the Government of India had under consideration the complete reorganization of both these services and was not prepared to make any definite pronouncement of policy at the present moment.

Sir William Vincent, speaking on behalf of the Government, paid a high tribute to the work done by the I.M.S., not only for India, but for the peoples of other parts of the world. Mr. Sastri was anxious that a larger number of Indians should enter the service; 40 per cent. of the candidates who passed at the 1914 examination were Indians. Referring to Mr. Sastri's statement as to the willingness of Indian medical men to act as a war reserve, he said that many subassistant surgeons who by the terms of their engagement were liable for military service,

had resigned when called upon to fulfil their obligation. Dealing with the proposal to reject the recommendation of the Public Services Commission to improve the pay of the I.M.S., Sir William Vincent said that the difficulties which existed before the war in obtaining recruits would be enhanced after it, and he declared that the Government of India declined to bar itself from maintaining the high qualifications for a medical service which had conferred almost inestimable benefits on the country. At the conclusion of the discussion the resolution was rejected by 38 votes to 15.

The Indian Budget for 1918-19 was presented at a meeting of the council on March 1st; the main features were a surplus of nearly six million pounds sterling and the announcement that there would be no alteration in taxation. There had been an increase in revenue under nearly every principal head, the only marked exception being opium, which showed a decline of £320,000.

Surgeon-General W. R. Edwards, C.B., C.M.G., has been appointed an additional member of the Legislative Council, the Governor-General, and has been awarded a good service pension of £100 per annum, with effect from April 1st, 1915.

Universities and Colleges.

UNIVERSITY OF GLASGOW.

At a meeting of the General Council last week the Rev. Dr. John Smith, convener of the Business Committee, said that it recommended the council to approve the desire of the university lecturers and assistants for improvement in representation, status, and remuneration, and to ask the University Court to take the request into early and favourable consideration. This proposal was unanimously accepted. Speaking on the minute dealing with the Carnegie Trust, the convener drew attention to the fact that the percentages of leaving certificates gained by new applicants during the last six years were as follows: 74.5, 87.1, 87.6, 91.2, 91.3, and 92.4. The increase, he said, showed the real need for the new university ordinance governing the admission to universities; it would, he hoped, soon receive approval. Finally, he observed that of the 192 names in the obituary list for 1917, 100 were of men who had given their lives in the service of the country.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At an extraordinary comitia on May 9th, the President, Dr. Norman Moore, occupying the chair, the following gentlemen, elected to the Fellowship at the last comitia, were admitted:

Walter Broadbent, M.D.Camb., Hugh James Moore Playfair, M.D.Lond., Frederick Lucien Golla, M.D.Oxf., Archibald Montague Henry Gray, M.D.Lond., Alfred Ellington Stansfeld, M.D.Camb., William Whiteman Carlton Topley, M.B.Camb., Charles Hubert Boud, M.D.Edin., Percy William Bassett-Smith, C.B., Sir Walter Morley Fletcher, M.D.Camb., F.R.S., Sir George Newnam, K.C.B., M.D.Edin.

It was resolved, on the recommendation of the Censors Board, that the licence to practise physic be restored to Mr. Edmund Lyall Haynes.

The President announced that the "Twilight Sleep" Committee had been constituted as follows: Dr. H. R. Spencer, Dr. G. Blacker, Dr. J. S. Fairbairn, Dr. H. Williamson, and Dr. H. R. Andrews.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary council was held on May 9th, when Major-General Sir George Makins, G.C.M.G., A.M.S., President, was in the chair.

Bradshaw Lecture.—Mr. D'Arcy Power was appointed Bradshaw lecturer for the ensuing year.

Issue of Diplomas.—Diplomas of membership were granted to 102 candidates found qualified at the recent examinations.

Presentation of Bust of John Scott.—This bust, by Chantrey, of John Scott, F.R.C.S., a member of the Council of the College from 1844 to 1846, was presented by Sir L. A. Selby-Bigge, K.C.B.

List of Members.—The Secretary reported that the list of members published in the *College Calendar* contained the names of some 2,224 members who were not registered under the Medical Acts of the United Kingdom, and that, while some could be traced as resident in the colonies and abroad, there were many whose addresses were not, and for some years had not been, known. The names of all members admitted before 1870 whose addresses cannot be ascertained (in number about 1,033), will be placed in a separate list, and such list will be omitted from the *Calendar* for 1918-19.

At the annual meeting of the Rockefeller Foundation additional gifts for war work to the amount of £37,470 were announced. Of this sum, £25,000 is to be applied to continue the war demonstration hospital of the Rockefeller Institute and £10,000 is allotted to the National Research Council of the Council of National Defence.

Obituary.

MAJOR T. HAROLD HUNT, R.A.M.C. (T.F.), died at Halifax on April 29th, aged 48. He was the son of the Rev. T. H. Hunt of Southport, and was educated at Owens College, Manchester, and the Yorkshire College, Leeds. He graduated M.B.Lond., with honours in 1895, B.S. in 1896, and M.D. in 1898. After serving as house-surgeon to the Leeds General Infirmary and at the Royal Halifax Infirmary he started practice in Halifax. In 1904 he was appointed to the staff of the Royal Halifax Infirmary and medical officer to the Halifax School Board. Later he was appointed medical officer in charge of the Barmerside Open-air School and Convalescent Home. He took a great interest in the School for Defectives at Halifax, one of the first three established in England. In 1915 he was appointed to the staff of the St. Luke's War Hospital, Halifax, with the rank of major, and the strain of this arduous work made great demands on a not very strong constitution. A colleague writes that there can be little doubt that Major Hunt died as the result of his military service. He was at the Royal Infirmary and the military hospital on April 28th but was compelled to return home, and within a few hours an acute attack of pneumonia developed which proved fatal early on April 29th. He was a member of the Halifax Division of the British Medical Association. He was buried with full military honours.

LIEUT. COLONEL THOMAS WILLIAM O'HARA HAMILTON, C.M.G., R.A.M.C. (ret.), died at Colchester on April 22nd, aged 57. He was the son of Colonel T. Hamilton of Malden, Surrey, and was educated at Trinity College, Dublin, where he graduated B.A. in 1880, and M.B. and B.Ch. in 1881. Entering the army as surgeon on February 3rd, 1883, he became surgeon-major on February 3rd, 1895, and lieutenant-colonel on February 3rd, 1903, retiring on November 4th, 1911. He served throughout the South African war from 1899 to 1902, was present in the advance on Kimberley, including the actions at the Modder River and at Magersfontein, in operations in the Orange River Free State, including the actions of Paardeberg and Wittebergen, and in the operations in Cape Colony, and received the Queen's medal with three clasps, the King's medal with two clasps, and the C.M.G.

DEPUTY SURGEON-GENERAL JAMES HENRY LOCH, Bengal Medical Service (retired), died at Guildford on April 9th, aged 85. He was the son of Rear-Admiral Loch, was born on September 21st, 1832, and educated at Edinburgh University, where he graduated M.D. in 1853. Entering the I.M.S. as assistant surgeon on December 20th, 1854, he became surgeon in 1866, surgeon-major in 1873, brigade surgeon, when that rank was first instituted, on November 27th, 1879, and D.S.G. in 1881. He retired on January 1st, 1889. He served in the Indian Mutiny in 1857-58; in the operations of the Oudh Field Force from January to June, 1858, taking part in the relief of Azimgarh and in the pursuit of Koer Singh, and received the Mutiny medal.

Medical News.

A NUMBER of Italian professors are about to pay a visit to the universities of Great Britain.

LORD LEVERHULME has been elected president of the Royal Institute of Public Health.

A NEW electro-therapeutic and massage department at the Great Northern Central Hospital, Holloway Road, has been completed, and is prepared to deal with 10,000 attendances a year.

THE library of the Royal Society of Medicine will be closed on Saturday, May 18th, and Monday, May 20th, but members of the R.A.M.C. and other medical services will be admitted.

AN American Congress on Infancy will be held at Monte Video under the patronage of the Republic of Uruguay in December, 1918 (19th to 22nd). Representatives of all the countries of America will take part in the proceedings. The president is Dr. L. Morquio.

DR. G. J. MURIEL, who has resided in Whitehaven for fifty years and is consulting surgeon to the Whitehaven and West Cumberland Infirmary, has been appointed to the Commission of the Peace for the county of Cumberland. He was president of the Border Counties Branch of the British Medical Association in 1898-99.

THE first number of a *Review of War Surgery and Medicine* was issued from the office of the Surgeon-General of the United States Army in March, 1918. It is to appear monthly, and to be devoted to abstracts of medical literature relating to the war.

AN appeal, signed by the Rev. W. J. Barton and Mr. Edred M. Corner, M.S., F.R.C.S., honorary secretary of the Old Epsomian Club, is made for funds to rebuild the nave of the chapel of Epsom College in harmony with the chancel, and to place in it a suitable memorial bearing the names of the old boys and masters who have sacrificed their lives in the war.

THE *American Journal of Ophthalmology* has been amalgamated with the *Annals of Ophthalmology*, the *Ophthalmic Record*, *Ophthalmology*, the *Ophthalmic Year Book*, *Ophthalmic Literature*, and the *Annales de Ophthalmologie*. The new publication, which will appear monthly, owes its existence largely to the efforts of Dr. Edward Jackson, of Denver, Colorado, who is its editor. The first number appeared in January, 1918.

IN the Probate Court on May 13th leave was given to presume the death of Sir Marc Armand Ruffer, M.D., C.M.G., who, while engaged in Red Cross work, was on board H.M. transport *Arcadian* when she was torpedoed and sunk by a U-boat near the Island of Milos on April 15th, 1917. An obituary notice appeared in the *JOURNAL* of May 5th, 1917, p. 602.

THE Medical Committee of the Royal Hampshire County Hospital, Winchester, after full consideration, have come to the conclusion that the grant of 5s. 6d. per man per diem offered by the Ministry of Pensions to the hospital for the maintenance of war pensioners will only just cover such maintenance. They feel that the medical treatment of these patients, which is a matter of great national importance, should be paid for by an adequate and direct remuneration of the staff, and that this should be on an entirely separate basis from that of maintenance.

MM. CHABONIER and BLETON communicated to a recent meeting of the Société de Biologie in Paris certain observations they had made of the frequent occurrence of polyarthritis in the course of the treatment of patients with arsenobenzol (especially 914). The joints remained painful for three or four weeks. A similar condition of polyarthritis was observed to occur in a certain number of non-syphilitic cases treated with arsenobenzol; the condition would therefore seem to be attributable to the drug.

Letters, Notes, and Answers.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Referees Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.

AN OLD MEMBER writes: I have just read in the *JOURNAL* of May 11th, p. 538, the report of the annual meeting of the above society, and I consider a great injustice was done to old members by the passing of a resolution (at the instigation of the committee) stopping the payment of the usual bonus, after 1918, to those members who attain 65 in the sickness branch—the mainstay of the society—whilst it was agreed to pay a bonus to the life assurance branch. Considering the fact that the committee, in their printed rules, objects, and special reasons for joining the society, have made special stress on the payment of a bonus, I think it is "unjust," to say the least, to suddenly stop it, and it is especially unfair to those who have been members for over twenty-five or thirty years, and naturally have looked forward to receive their well-earned bonus. According to the opinions of the late secretary Mr. Addiscott, and Mr. Cresford, the actuary, in their report for 1903, they considered it to be "inequitable" to those members shortly reaching the age limit not to receive some benefit of the existing surplus. In these days of war stress it is doubly hard to act in this unfair manner, especially when the society is in a good financial position. I am glad there were present some members who disagreed with the recommendation of the committee, and who voiced their opinions, but who were outvoted.

BABY WEEK.

IN connexion with Baby Week celebrations the National Association for the Prevention of Infant Mortality is organizing a conference to be held at the Central Hall, Westminster, on July 2nd and 3rd. Dr. J. W. Ballantyne will open a discussion on antenatal and neonatal factors in infant mortality, under the chairmanship of Sir Arthur Newsholme; Lady Barrett will open a discussion on institutional *versus* domiciliary treatment of the lying-in mother, under the chairmanship of Sir Francis Champneys; and a discussion on mothers' pensions will be opened by Dr. Harold Scurfield, M.O.H. Sheffield. Lectures on infant care will be given by Dr. Eric Pritchard, Dr. Maurice Craig, Dr. H. C. Cameron, and Dr. C. W. Saleeby, mainly for elementary school teachers. There will also be a practical demonstration on the teaching of mothercraft to schoolgirls, and a lecture on the hygiene of infancy.

TUBERCULIN TREATMENT OF PULMONARY TUBERCULOSIS.

DR. EDWARD E. PREST (Ayrshire Sanatorium, new Cumnock) writes, in reply to Dr. Adam Moss (p. 497), that though tuberculin treatment has been largely used during the last ten years, he supposes that there is not at the present time any one who regards it as satisfactory. Dr. Prest thinks that the cause of most chronic disease is allowing patients to walk about, in the early active stage with a temperature such as 101°. While a chronic case such as Dr. Moss describes is occasionally benefited by tuberculin, the majority of such cases are not. Isolated cases are, Dr. Prest considers, of no value in estimating the results of treatment.

THE CASES ATTRIBUTED TO BOTULISM.

DR. E. H. M. MILLIGAN, D.P.H. (Bath), writes to suggest that in investigating the cause of the obscure cases of nervous disease which have been described as perhaps due to botulism, attention should be given to the possibility of the presence of the *Diplococcus intracellularis*, the cause of cerebro-spinal fever, for in many cases the cerebro-spinal symptoms are absent and gastro-intestinal or other symptoms predominate.

PENETRATING WOUND OF HEART (CIVILIAN PRACTICE).

DR. S. D. CLIPPINGDALE (London, W.) writes: Mr. Wightman's interesting case of a child who lived five days after receiving a penetrating wound of the heart is not without precedent. Dr. Thomas Davies, in his *Diseases of the Heart and Lungs* (London, 1835), mentions the case of a patient, also a child, who lived thirty-seven days with his heart transfixed by a splinter of wood three inches long. As in Mr. Wightman's case, a *post-mortem* examination was made.

TRIVIAL WOUNDS OF THE FINGERS.

DR. J. A. ROOTH (Brighton) writes that he has been struck by the fact that trivial pricks and cuts of the fingers frequently suppurate. Remembering the frequency of pyorrhoea and carious teeth he attributes this to the sucking of such wounds and suggests that lecturers on first aid should point out that the habit is dangerous.

A SOCRATIC DIALOGUE.

A. The matter as regards the Athenian physicians and the new laws of military service seems to me to stand thus: In the first place, we admit or we do not admit that it is the paramount duty of every citizen of whatsoever age and condition to do all that lies in his power to aid the state in its endeavour to overthrow our potent enemy, the Lacedaemonians, who seek to destroy us and our allies and to impose their will upon the world.

S. That is well said. We will agree that this obligation is recognized by every good Athenian.

A. It follows, then, that my brother physicians—who are by no means behind their fellow citizens in patriotism—are ready to do all that is asked of them in furtherance of this good cause.

S. Here, as it seems to me, you fall into some confusion of thought.

A. How so? Do you deny the public spirit of our physicians?

S. It is far from my wish to deny this, and indeed it would be foolish to do so, for the contrary is well known to me and to all sensible Athenians.

A. Where, then, has my reasoning led me astray?

S. I will try to answer that by putting one or two simple questions to you. Is it not the fact that physicians are members of a learned profession?

A. I should be sorry to deny it.

S. And are they not by their training and through the exercise of their art better able than most men to judge their fellow citizens both in health and in sickness?

A. That assuredly is my belief.

S. Then we are agreed, I take it, that the physician wishes to do his utmost for the state in this crisis, and that he is less likely than others to be deceived by those who would point out his duty to him? Is that not so?

A. I see what you are leading up to; but the physician no less than any other citizen must submit himself to the authority of those who are entrusted with the conduct of affairs, otherwise there would be an end to government, and we should be delivered into the hands of the Lacedaemonians.

S. It is clear to me that no sophistry can prevail against your sturdy patriotism. Let us therefore abandon all dispute as to the right of private judgement when the state is in danger.

A. I acknowledge your concession. To proceed: it is beyond question that physicians, whose obligation to serve the state is not a whit less than that of any other man, have had and still have under the new laws special treatment. As heretofore they are to be taken for service with the army or left to minister to the needs of the civil population at the discretion of their peers—a thing conceded to no other section of the community. Furthermore, when they join the armed forces they are allowed to exercise their own calling almost by right, and they receive higher pay than those who have no choice as to how they shall serve their country when called upon to do so. Such privileges being ours, my blood boils when I hear it argued by factious persons that physicians, in virtue of their calling, or by reason of anything else whatsoever, have a claim to be treated yet more tenderly than other citizens.

S. I hope I should be the last to deny the force of much that you have said. Nevertheless, there are certain remarks which occur to me. First, I would ask you whether this differential treatment has been accorded to the physicians by reason of some special feeling of tenderness towards them as a body or as individuals?

A. I cannot read the minds of other men, least of all those of our rulers.

S. Next I think you should explain why it is that the new laws raising the age of military service have added five years to the obligation of the physician as apart from other men.

A. It may be in order to balance the five years at the other end of the scale, during which the student of our art is exempt from the heat of battle.

S. You argue, then, that it is an ingenious measure of justice?

A. Perhaps I should withdraw that. On second thoughts I perceive the reason to be that physicians above all men deal in an indispensable commodity, for which the demand has grown greater through the operations of war.

S. That is a more likely explanation. And may not that be also the answer to my previous question as to the special consideration shown by our rulers towards your calling?

A. It may be.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

Subscriptions to the Second Appeal.

The following subscriptions and donations to the Fund have been received during the week ending May 11th:

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE BACTERIAL FLORA OF WAR WOUNDS: INFLUENCE OF TREATMENT.

BY

SIR KENNETH GOADBY, K.B.E., M.R.C.S.,

L.R.C.P., D.P.H. CANTAB.,

HONORARY BACTERIOLOGICAL SPECIALIST, ROYAL HERBERT HOSPITAL,
WOOLWICH; MEMBER OF THE WAR OFFICE COMMITTEE
FOR THE STUDY OF TETANUS.

(Report to Medical Research Committee.)

The wounds of war differ from the majority of wounds in civil life in that they contain a very large number of bacteria, resulting in prolonged suppuration, slow healing, and deforming cicatrization. In no industrial wounds, except a limited number occurring in agriculturists, does soil contamination play such an important part as in the wounds of war, and as the bacteria of the soil figure largely in the flora of war wounds, a comparative study of the bacterial flora of the wounds extending over long periods may throw some light on the benefit of one or other method of wound treatment, and suggest a direction in which effort should be concentrated.

From the commencement of the war I have made routine bacteriological examinations of the convey cases arriving in certain home hospitals; these examinations have been conducted in a uniform manner throughout. The routine adopted has been (a) the examination of film preparations

DIAGRAM I.—Percentage incidence of spores (shaded), bacilli (black), and cocci (white), in Gram-stained films. Periods of six months, 1915-17.

(b) the discharge material stained by the Gram method, (c) the cultivation of the discharge material on (1) glucose broth, (2) sterilized milk, (3) minced autoclaved meat. The cultures were examined in the ordinary routine manner and where necessary plated out, or the cultures carried far enough to determine the various groups in which the organisms are scheduled. A considerable amount of effort was expended to commence with in perfecting anaërobic apparatus, and the results and methods have been published elsewhere. Certain general conclusions regarding the bacteriological flora of wounds have been reached. In the early part of the war, especially in the winter of 1914-15, many wounds arriving in home hospitals were extremely septic, sloughing, and emitted an offensive putrid odour. At intervals during the succeeding years a slight return to this condition has occurred from time to time, during periods of stress, but the general physiological character of the wounds has undergone a steady and progressive improvement. In the early period the number of spore-bearing organisms found in films made from the wound discharges was large. Three types of sporing organisms were observed: (1) Bacilli with a central spore, staining deeply by Gram's method; (2) bacilli containing a sub-terminal spore; (3) bacilli with a rounded or oval end-spore. In the more putrid wounds all three classes were represented, but mainly the third, whereas in the cases of acute localized oedema with bubbles of gas in the discharge and, in a few cases, acute gas gangrene spreading from the

wound, the main class of organism present was the central spored bacillus. During 1916 and the first half of 1917 these organisms were less often met with; during the last half of 1917 a limited number only were observed.

Diagram 1 shows the relative percentage incidence of the various classes of organism met with in the pus films. The cases are collected into periods of six months, commencing with 1915, and the number of cases with spore-bearing organisms shows an extraordinary and progressive diminution, except for a slight rise during the second half of 1916. These relative proportional diagrams do not convey the intensity of the infection in any given wound, but merely the percentage of cases in which spore-forming bacteria were found in the pus films. The other two columns represent—the white column cocci, both streptococci and staphylococci, and the black column bacilli, both Gram-positive and Gram-negative. During the first two years Gram-negative bacilli belonging to the *coli* and *proteus* groups were frequently met with, but the incidence of these organisms, especially the *proteus* group, has diminished during the last nine months. The cases from which these examinations are made were all examined within twenty days of wounding. About 33 per cent. were examined within the first week; this proportion has been maintained throughout, so that the groups of cases remain fairly comparable. The results of treatment appear, therefore, to have progressively diminished wound infection, but it by no means follows that the absence of bacteria in the films of the discharge is indicative of the freedom of such wounds from bacterial infection.

Diagram II shows how far this divergence exists; in this diagram the proportional incidence of bacteria in the

DIAGRAM II.—Percentage incidence of anaerobic bacilli in wounds 1 to 20 days old. First examination on admission in home hospitals. Black = Saccharolytic group, type *B. perfringens* (*welchii*) (cultivation). White = Proteolytic group, type *B. sporogenes* (cultivation). Shaded = End-spore group, type *B. tetani* (cultivation).

wounds obtained by cultural methods is given in percentage proportions. The columns relate to three types of anaerobic bacteria: the black, the saccharolytic group, of which *B. perfringens* or *B. welchii* may be taken as the type. The white column, bacilli of the proteolytic group, of which *B. sporogenes* or the bacillus of malignant oedema may be taken as the type; whilst the shaded column indicates the number of organisms forming end spores of the tetanus and other allied groups. It must not be supposed that this class represents tetanus bacilli; it merely indicates the large class of end-sporing bacilli to which the tetanus bacillus belongs.

During the first half of 1916 there was an apparent diminution in the number of sporing anaerobes isolated from the wounds, but from this period forward to the end of 1917 the incidence again rises steeply. From 1915 to June, 1916, the number of proteolytic and saccharolytic organisms remains about the same. A considerable rise occurs in the second half of 1916, and the wounds from this period remain at a higher level of infection, the only diminution being a decrease in the number of proteolytic organisms in the second half of 1917. It is freely admitted that the number of cases examined is extremely small in relation to the total number of wounded. On the other hand, the series has been entirely performed by one observer and according to a constant routine. A possible

explanation of the smaller number of infected wounds culturally up to June, 1916, may perhaps bear some relation to the larger number of bullet wounds, and there is a possibility that from 1916 onwards shell wounds have figured more largely, causing a deeper infection of the tissues.

A comparison of Diagrams I and II points very strongly to the inadequacy of simple film examination in determining the bacterial content of any given wound. It must be pointed out in relation to Diagram II, as to Diagram I, that the percentage occurrence of the groups indicated in the table is no criterion of the mass extent of the infection, as the cultivations were always re-examined at intervals for fourteen days to allow of the growth of any organisms that were present. The diminution in the flora of the wounds, as estimated by film preparations given in Diagram I, together with the apparent increase in the numbers of cultivable bacteria given in Diagram II, suggested some influence which, at any rate, was diminishing the mass infection of the wound. Unfortunately, it is only since June, 1917, that the medical field cards have been available; before this date no information was forthcoming as to the earlier treatment of the wound except by hearsay. From June, 1916, the field cards give a record of the number of wound excisions performed in the casualty clearing stations, as a rule within twelve hours of wounding; it was thought, therefore, that a comparison of the percentage flora in excised wounds and non-excised wounds might give some information as to the possible cause of the diminution.

In Diagram III I have therefore collected the percentage incidence of anaerobic flora from 100 excised wounds examined from June to December, 1917, and of 100 non-

DIAGRAM III.—Percentage incidence of anaerobic flora in excised wounds compared with non-excised wounds. Shaded = Percentage of wounds with sporing bacilli in the pus films (films from pus). Black = Percentage of wounds with saccharolytic group (cultivation). White = Percentage of wounds with proteolytic group (cultivation). Dotted = Percentage of wounds with end-sporing bacilli (cultivation).

determined by cultivation; white, proteolytic group, determined by cultivation; dotted, end-sporing bacilli. It will be seen at once that in the 100 excised wounds all four classes are greatly diminished. Not only have the spore-bearing organisms in direct films diminished, but the spore-bearing bacilli obtained by cultivation also show a considerable diminution, whilst both proteolytic and saccharolytic groups are diminished, the proteolytic to the greatest extent. It may therefore be fairly inferred that the immediate excision of wounds performed at the casualty clearing stations has a very great influence in diminishing the number of bacteria cultivable from the wounds five to twenty days afterwards.

Influence of Antiseptics on the Bacterial Flora of Excised Wounds.

The possible influence of the antiseptic used on the diminution of bacterial flora naturally arises in connexion with these wounds. The 100 excised wounds were therefore examined carefully to determine if any influence

could be traced to the antiseptic used. Fifty of the wounds had been treated with hypochlorite, with or without Carrel tubes; forty had been treated by bipp. The remaining ten had various forms of antiseptics, including flavine and brilliant green. The two chief antiseptics in use were hypochlorite and bipp. On examining the percentage of the flora in each case there was no difference whatever attributable to either antiseptic. In each class—hypochlorite and bipp—the incidence of sporing bacteria and *Bacillus welchii* was 30 per cent.; for the proteolytic type 29 and 31 per cent. respectively. If either of these two antiseptics had any specific action in reducing one or other variety of bacterial infection, one would have expected it to show in a series of wounds treated in the same manner. So far, no sufficient number of cases treated with no antiseptic from the moment of excision is available.

Certain practical disadvantages are associated with both these antiseptics.

1. Hypochlorite: Cases treated with Carrel tubes rarely arrive in home hospitals with the tubes in the position in which they were originally placed, and on the rare occasions on which they are still in the wound the tubes are generally so blocked as to render them entirely useless. On the other hand, as the Carrel tubes are passed through the bandages and fresh hypochlorite is passed down the tube, some of it finding its way into the wound or into the dressing, the chief advantage appears to be that the bandages are not removed in the ambulance train and the case submitted to the chance of fresh infection.

2. Bipp: A certain number of wounds arrive with so much bismuth inserted that it partially obscures the finer structure in fractured bones. A certain number of cases—10 per cent. of 100 cases treated with bipp—have shown symptoms of poisoning due to bismuth—blue line of the gums, blue tongue, and blue patches on the buccal surface of the cheeks, gastritis, diarrhoea and vomiting. Three instances have been seen of iodine poisoning with mental symptoms. In cases of poisoning attributable to the bipp very large quantities had been made use of.

Latent Infection.

This has proved a very common sequela, and has been observed principally in certain classes of wounds.

1. *Flesh wounds*, especially penetrating, lacerated wounds. In these wounds histological examination of the tissue in the immediate neighbourhood of the wound shows changes similar to those associated with gas gangrene, and described in my previous papers,¹ and also the type of muscle degeneration described by McNee in acute gas gangrene. Reference to Diagram III demonstrates that organisms belonging to the saccharolytic gas-forming group are extremely common. There is overwhelming evidence that a large proportion of wounds suffer from incipient gas gangrene, but that the process is arrested by the action of the tissues. I have already published photographs of tissues showing active phagocytosis in incipient gas gangrene.²

2. *Bone injuries*.—Latent infection, as distinct from persistent local sepsis, is more common in bone injuries than in flesh wounds. Comminuted fragments have rarely been found united, even after long intervals, and comprise by far the greater number of sequestra removed at subsequent operations. The sequestra removed from such cases—six, nine, twelve, and eighteen months after the original injury—often show the sharp edge of the original fracture. Radiographical examination and histological examination, together with bacteriological observations, show two main forms of sequestra—(a) hard, (b) soft. The softening sequestra appear to be bacteriologically related to *B. welchii* and the streptococcal groups, the hard sequestra more often to the proteolytic groups, *B. sporogenes*. General local loss of opacity to the x rays is associated with loss of lime salt in the bone, and is apparently associated with the saccharolytic group, though no definite acid reaction occurs in the tissues owing to the action of the buffer substances. Histological examination in latent infection, persistent infection, and closed cavities containing metal fragments or fragments of bone, show scattered organisms in small clusters enclosed in a wall of fibrous tissue. The tissue in the immediate neighbourhood of such bacterial nests is often normal in structure. In ankylosed joints which have been excised after complete healing of the external wounds bacteria have invariably

been found sequestered in the partially destroyed cartilages. Infected areas are met with here in close proximity to normal tissue, and more organisms have been found at the extreme limits of the affected and damaged areas than in the centre of fibrous degenerated tissue. One of the difficulties attendant on subsequent operations on joints, especially excision, is the secondary suppurations which undoubtedly arise from these loculi containing remnants of the original infection.

*Wounds Entirely Healed but Breaking Down after
a Long or Short Interval.*

Many wounds have been examined belonging to this class; they are frequently wounds involving bone, often with very slight bone involvement and no fracture. Histological and bacteriological examination give the same findings, whilst the penetration of the bacteria into the bone extends a considerable distance either side of the original lesion. These wounds break down again after trivial injury or over-exercise. A histological examination of tissue excised near such wounds shows the infection mainly at the junction of the normal and fibrous tissue. The outcome of bacteriological observations on a large series of wounds of latent infection, together with histological examination of excised tissue, points to the physiological action of anaërobic bacteria rather than to general systemic toxæmia as the underlying cause of the persistent infection. The most persistent organism is the *B. sporogenes*, which is in itself of low pathogenic power. It can, however, survive for a long time and in culture tubes, when associated with streptococci or organisms of the *coli* group, and undergoes cyclic development, spores forming and germinating slowly but persistently, with the result that the material becomes ultimately entirely digested. In cases heavily infected with the *B. sporogenes* persistent local oedema has been observed. Histologically, minute general thrombosis of vessels in the immediate vicinity of the wound is common; the thrombus may even spread up through the smaller vessels and project into the larger. Histological examinations of these cases show that the "splash" effect produced in the soft tissues by the velocity of the projectile extends over a considerable distance, that numerous radiating cracks in the tissue occur which become the seat of hæmorrhage. The blood clot formed contracts, associated with the discharge of serum from the wound, coincidentally the bacteria make their way into the cracks, doubtless by capillarity, and subsequently become shut off from the main wound cavity by fibrous tissue and remain latent. There is some indication that this fact has an important bearing on the practical question of the movement of wounded men. It certainly has a very practical bearing on the deep infection of the wounds.

Summary.

In summarizing my observations on wounds in home hospitals from 1915 to the present time it appears—

1. That the mass infection has diminished progressively, but that
2. The persistence of anaërobic bacteria has not undergone similar qualitative reduction.
3. That by the use of the two antiseptics of which statistics have been available (bipp and hypochlorite) no great diminution in anaërobic flora has been effected.
4. That latent infection as opposed to persistent infection is of great importance in "subsequent operations," and that latent infection is determined by the treatment of the case in the first week of the injury, possibly in the first three days.
5. That in latent infection organisms are found in close proximity to healthy tissue and therefore in a region likely to become the site of an incision in a subsequent operation.
6. That bone fragments split off at the original injury invariably become sequestra, probably due to the proteolytic action of the bacteria rather than to destruction of blood supply.
7. That of the various methods which have so far been made use of in the immediate treatment of wounds, immediate excision of the lacerated tissues is apparently the only one that has produced a marked diminution in the anaërobic flora of the wounds.

NOTES ON VIBRION SEPTIQUE.

BY

MURIEL ROBERTSON, M.A.,

LISTER INSTITUTE.

THE following is a brief account of the anaërobic organism known variously as the *Vibron septique* and the bacillus of Gohn and Sachs; the name *B. oedematis maligni* has also been used for it.

The conflicting accounts of early writers and the very real difficulty due to the close symbiotic association of widely differing species of anaërobes has obscured our knowledge of this type. *Vibron septique* is very easily passed over in mixed culture, so that its presence has often escaped the notice of workers dealing with wound infections. I propose to use the name *Vibron septique*, under which I include the bacillus of Gohn and Sachs; *B. chauvei* is an allied type, but is a different organism.

The name *Vibron septique* is here applied to a group of strains which are in complete agreement with each other in (a) morphology; (b) cultural characters, including the reactions upon various sugar media; (c) pathogenicity and reaction in the animal body. They do not, however, fall into one group upon the agglutination reaction.

From the trend of modern research it is becoming clear that in many cases the organisms responsible for any given pathological condition must be looked upon as a series of very closely allied types, which can in certain instances be separated from each other by various slight *differentia* and notably by the agglutination reaction. It may eventually be useful to subdivide the group into subgroups, possibly with specific names. It is proposed to deal with the agglutination reactions of *Vibron septique* in another publication. In general, it may be said that in working with anaërobes it is premature to conclude that a strain represents a separate species because it produces specific agglutinins.

The following is a list of the strains studied:

1. *Vibron septique*, Pasteur Institute strain.
2. B. R., Pasteur Institute strain.
3. *V. septique*, strain "Amatzi"; derived from blood culture; from Dr. Weinberg.
4. *V. septique*, strain "Cairny"; from fatal case of gas gangrene.
5. *V. septique*, strain "Summers"; blood culture from case of gas gangrene.
6. *V. septique*, strain "Dynes"; from fatal case of gas gangrene.
7. *V. septique*, strain "Prior"; from case of gas gangrene.
8. *V. septique*, strain "Alexander"; from hæmorrhagic blister fluid in a case of gas gangrene.
(Strains 4 to 8 were supplied by Captain Stokes.)
9. *V. septique*, strain "J. L."; from case of gas gangrene isolated by Miss Hempl.
10. *V. septique*, strain "James"; from case of gas gangrene.
11. *V. septique*, strain "Erissons"; from case of gas gangrene.
12. *V. septique*, strain 141; from case of gas gangrene.
13. *V. septique*, strain 133; from case of gas gangrene.
(Strains 10 to 13 were supplied by Captain Henry.)
14. *V. septique*, strain 227; from wound of patient forty-nine days after wounding; no symptoms of gas gangrene.
15. *V. septique*, strain 145; from wound of patient seven days after wounding; no symptoms of gas gangrene.
16. *V. septique*, strain "Jerral"; from wound of patient without symptoms.
17. *V. septique*, strain "Bedford"; amoebic abscess of brain; material from Captain Armitage.
18. *V. septique*, "Milk" strain, isolated from milk.
19. *V. septique*, "Milk Con." strain, isolated from milk.
20. *V. septique*, strain "George A."; from case of gas gangrene developing upon operative treatment of a healed wound.
21. N. L. *V. septique*; strain isolated by Miss Hempl from wound of patient without symptoms of gas gangrene.

The following were studied for comparison:

22. *B. chauvei*; from case of black quarter; from Sir John McFadyean.
23. *B. chauvei*, culture isolated by Dr. MacIntosh from Rauschbrand muscle from Denmark.
24. *B. oedematis*, strain "Jolly"; from Dr. Weinberg, from case of Dr. Dalyell.
25. *B. oedematis*, strain "Delombre"; from Dr. Weinberg.

I have much pleasure in expressing my cordial thanks to the many colleagues to whom I am indebted for material from cases in their charge, or who have most generously placed their cultures at my disposal. My thanks are due to Dr. Roux, Dr. Weinberg, Dr. MacIntosh, Miss Hempl, Captain Armitage, N.Z.M.C., and Sir John McFadyean. I am quite especially indebted to Captain A. Stokes, D.S.O., R.A.M.C., and to Captain Henry, R.A.M.C., for much valuable material and for kind co-operation during the course of the work.

Morphology.

The *Vibron septique*, like many anaërobes, has a rather wide range of variation in morphology according to the circumstances in which it develops.

Typically, in a young culture in meat medium it appears as a Gram-positive rod of varying length considerably thinner than

B. welchii and in size closely resembling *B. sporogenes*; spores are formed with great freedom, and may be found at any stage of development. They may be centrally placed, and in short rods; they may occupy practically the whole extent of the organism, producing barrel-shaped or clostridial forms. The spores are, however, very frequently subterminal or even terminal; the shape of the fully developed spore is often oblong rather than oval, the ends being slightly flattened.

When grown on inspissated serum the appearance may be extremely varied—club-shaped individuals, bulbous, deeply staining types, filaments and the "navicular" or "citron" forms described later may all be present as well as the rods and spores already mentioned. In Noguchi tubes containing fresh tissue these "citron" and club-shaped individuals may also appear.

Apart from these forms just mentioned there is nothing very characteristic in the morphology of *Vibrio septique* in culture which would distinguish it from other anaerobes.

Motility.

In young (twenty-four hour) cultures and in the freshly taken oedema fluid of recently dead animals the organism is motile.

Cultural Reactions.

The cultural reactions are as follows:

Colony.—Surface colonies are semitransparent and rather delicate; the edges may be crenated, and there may sometimes be a tendency to form flat or branching outgrowths; woolly filaments of the tangled thread type are not formed, and the colonies do not grow down into the medium. Surface colonies

Broth.—In plain nutrient broth the growth is rather feeble; the medium becomes turbid in twenty-four to forty-eight hours and, later, the growth sinks to the bottom of the tube. In glucose broth the growth is very vigorous, and the sinking of the organisms is very striking; this occurs after about thirty-six to forty-eight hours of incubation. There is often a lag of about twelve to eighteen hours during which growth may fail to appear, even when a very vigorous proliferation is about to occur within the next twelve hours.

Meat.—In this medium there is vigorous growth and considerable formation of gas. A vivid pink colour is produced which varies in exact hue according to the constituents of the medium (the colour is darker in heart muscle and brighter in skeletal muscle, etc.); after a time the bacteria sink down so that the fluid above the meat becomes as clear as before inoculation. The colour may gradually fade from the meat on exposure to air. There is no blackening and no putrefactive odour, and the meat does not become soft and friable. Meat covered with paraffin is a very good medium for the cultivation of this organism.

Inspissated Serum.—*Vibrio septique* grows freely on this medium in an anaerobic jar; there is no liquefaction, not even the faintest pitting of the surface after weeks of incubation. The morphological range of the bacillus on inspissated serum is very great—club-shaped individuals, deeply staining oval or bulb-shaped types, "citrons," and filaments may all occur. Spores are formed very readily on this medium, and a sealed culture may be left on one side for more than a year without any apparent loss of vitality. The subcultures then made show no abatement of vigour and retain their pathogenicity for laboratory animals.

Alkaline Egg Fluid.—The medium becomes uniformly opaque without the formation of a clot.

FIG. 1.—*Vibrio septique*, twenty-four to forty-eight hour meat culture. Mag. 1,500.

FIG. 2.—*Vibrio septique*, Noguchi tube culture, showing rods, spores, and a "citron" type. Mag. 1,500.

FIG. 3.—*Vibrio septique*, from muscle of guinea-pig. Post-mortem specimen; "citrons" and club-shaped type are shown. Mag. 1,500.

FIG. 4.—*Vibrio septique*, from liver of guinea-pig, showing "citrons," oval and bulb forms. Mag. 1,500.

require good conditions of anaerobiosis; a serum agar or glucose serum agar medium is favourable to growth. On salicin agar with or without serum the colony is larger, and while it retains its rather translucent character the whole appearance is more robust. Plates should be dried before spreading, as there is a certain tendency for *Vibrio septique* to grow in a uniform surface film instead of in discrete colonies. Good surface colonies can be obtained by stroking a loop dipped in the inoculum over three or four serum agar slopes in succession; one of the slopes generally yields clean discrete colonies which can be picked off.

Deep Colonies.—These have a transparent or semi-transparent appearance; the centre is not very compact, and the edges show coral-like branchings.

Characters in Milk.—When grown in milk, either in an anaerobic jar or in paraffin-covered media in an ordinary incubator, acid is produced, and, finally, after three to seven days, there is clotting, with or without the production of gas. If the sowing has been large and the culture is growing very vigorously the acid and clot reaction may be more rapid and the production of gas more obvious, but the delayed reaction is the more frequent, especially in recently isolated strains.

Noguchi Tubes.—A broth or glucose broth tube into which a piece of fresh liver or kidney, taken under sterile precautions from a rabbit or guinea-pig, has been dropped forms a most excellent medium for the growth of *Vibrio septique*. The citron forms occur in this medium and they afford a useful diagnostic feature.

Sugar Reactions.—These are quite definite, and are set out in the accompanying table; *B. welchii* (one type only), *B. oedematiens*, and *B. chauvei* are also shown for comparison. The medium for these tests may be casein digest broth, to which is added the requisite sugars in concentrations of 1 to 1.5 per cent.; litmus or the alkaline egg fluid, as described by Henry, may be used as indicators. The readings should be made at forty-eight to seventy-two hours. This medium can be used sealed with liquid paraffin. Serum litmus agar slopes made up with the desired sugars can also be used with success but require a good anaerobic apparatus.

Pathogenicity and Animal Reactions.

Vibrio septique is pathogenic for guinea-pigs, pigeons, rabbits, and mice; all the strains dealt with have retained

Table of Cultural Reactions.

Name.	Meat.	Milk.	Inspissated Serum.	Glucose.	Levulose.	Galactose.	Saccharose.	Maltose.	Lactose.	Inulin.	Salicin.	Mannite.	Dulcitol.
<i>Vibrio septique</i> ...	Gas: pink colour; no blackening	Acid: clot after 3 to 6 days	No liquefaction	+	+	+	-	+	+	-	+	-	-
<i>B. welchii</i> ...	Gas: pink colour; no blackening	Acid: rapid clotting with evolution of gas	No liquefaction	+	+	+	+	+	+	+	-	-	-
<i>B. oedematiens</i> ...	Gas: pink colour at first, then bleached	Acid after 4 to 6 days; very slow clotting	No liquefaction	+	+	-	-	+	-	-	-	-	-
<i>B. chauvei</i> ...	Gas: no blackening	Acid: clot after 3 to 6 days	No liquefaction	+	+	+	+	+	+	-	-	-	-

* Variable according to type.

their pathogenicity for these animals, some of them during years of culture under laboratory conditions. There is a certain variability in virulence, due in part to the conditions of growth. The most virulent cultures are twenty-four hour growths in glucose Nognchi tubes, glucose broth cultures of the same period come next, and ordinary broth is the least favourable medium for inoculation into animals.

The infecting dose for the particular type of laboratory animal used must be ascertained.

In some cases 0.1 c.cm. of a twenty-four hour glucose broth culture, or even less, will kill a 300 gram guinea-pig in twelve to eighteen hours; 0.5 c.cm. to 1 c.cm. is generally a lethal dose for a 300 gram guinea-pig, and the minimal lethal dose can be ascertained if desired. A sublethal dose of a virulent culture may be withstood by a guinea-pig without any symptoms, whereas a very slightly higher dose or even the same dose in another animal of corresponding weight will produce death with the typical lesions. Sublethal doses in guinea-pigs do not appear to produce any reaction. I have in no instance observed the recovery of an animal that had shown any symptoms of infection as a result of the injection of this organism. The occurrence of extensive oedema with subsequent recovery, which is so striking a feature of the reaction of guinea-pigs to sublethal doses of *B. welchii*, is absent when *Vibrio septique* cultures are used.

Post-mortem Appearances.

These are as follows:

There is an extensive blood-stained oedema, and a considerable amount of gas is developed in all the muscle tissue involved. The muscles affected have a characteristic deep red colour. There may be a collection of fluid in the peritoneal cavity and in the pericardium; this is not as a rule very evident in guinea-pigs which have died in twelve to twenty-four hours, but is a very well-marked appearance in rabbits which have succumbed to the infection after twenty-four to forty-eight hours. The suprarenal bodies may show a variable amount of redness, but this is not so regular nor so marked as in guinea-pigs which have died from infection with *B. welchii*.

There is no putrid odour. The pale digested appearance of the infected muscles so frequently seen in *B. welchii* infections is not seen with *Vibrio septique*.

B. oedematis in guinea-pigs produces a gelatinous oedema quite colourless, with little or no gas; the muscles involved are pale pink in colour.

Microscopical Appearances.

The microscopical appearances are as follows:

Film preparations stained by Gram's method, made from the muscle of an animal which has died of infection by *Vibrio septique*, show rods and the characteristic citron or navicular forms. They are of very varying length; they have a pale granular appearance, and generally contain a deeply staining portion at one end of the body or at both. Sometimes the granular part may take up the stain with somewhat greater intensity, but there is always a differentiation between the granular part and the deeply staining points. These "citrons" are stages in a type of spore formation that takes place only in the animal host or in the presence of live tissue or in serum. This is not the only type of spore formation which takes place in the host, the ordinary method whereby the spore arises in the rod also occurs. In addition to the "citrons" large club-shaped types which appear to be swollen rods occur—these are not very frequent in muscle; oval or bulb shaped, deeply staining forms, often in short chains, may also be present. It should be noted that if the infection has run a very rapid course and if the post-mortem examination has followed immediately upon the death of the animal the "citrons" and spores may not have been formed at all or may be present only in small numbers. "Citrons" also occur in infections with *B. chauveii*, but are not known in any other type of anaerobic infection. It should be noted that *B. chauveii* has not so far been recorded as infecting man.

Films made from the peritoneal surfaces of the liver show a greater or less number of long snaky chains and filaments. These long filaments are characteristic of a *Vibrio septique* infection; they are not found in infections with *B. welchii* nor with *B. oedematis*. Mice and rabbits show the filaments quite as clearly as guinea-pigs. The citron, club, and bulb forms can be found in the liver as well as in the infected muscle.

Vibrio septique produces septicaemia, and the heart blood taken with aseptic precautions and inoculated into paraffin covered meat medium yields good cultures.

"Vibrio Septique" in Mixed Culture.

Vibrio septique growing with *B. sporogenes* or in mixed culture derived from wounds is extremely difficult to recognize, and even when its presence is suspected it may be a very tedious and lengthy process to unravel it from the other anaerobes present by growing on selective media and plating, etc. The injection of such a mixed culture, either grown in glucose broth for twenty-four hours or from a meat culture, into a guinea-pig or mouse will afford the post-mortem picture described above, and moreover the cultivation of the heart blood in meat medium will often give a pure culture of *Vibrio septique*. Should this heart blood culture not be pure at the first passage the predominant organism will certainly be *Vibrio septique*, and plating or a second animal passage will then purify the strain.

Vibrio septique in these mixed injections into guinea-pigs will outrun both *B. sporogenes* and *B. welchii*, and the animal usually dies of a *Vibrio septique* septicaemia, even when both the above mentioned anaerobes are present in the culture inoculated.

Such a mixed culture destined for injection into an animal should, however, always be freed from *B. welchii* by growing for two or three days in milk and then heating to 80° for ten to fifteen minutes; the heated material should be inoculated into meat medium and (after subculture into glucose broth if desired) then injected into the animal. In mixed culture the dose should be 1 to 1.5 c.cm. for a 300 to 400 gram guinea-pig and 0.25 to 0.5 c.cm. for mice.

Vibrio Septique in Wounds.

Vibrio septique, like other pathogenic anaerobes, may be present in wounds both of recent date and of long standing without causing any symptoms in the patient. It may, on the other hand, be responsible for a serious or even fatal case of gas gangrene. These acute infections usually occur within a few days of wounding, but may arise at any time, especially after operation. One of the strains here studied was obtained from a gas gangrene condition arising from the operative treatment of a wound healed for over two years, but which still contained a very small pocket of pus in the scar tissue.

In an active infection with *Vibrio septique* the organism may be present in the discharge from the wound, in muscle, in the fluid from haemorrhagic blisters, in the skin near the wound, and possibly in the blood stream. A careful examination of films from the muscle, or from the blister fluid, should any have been formed, or from the discharge, may show among other organisms the characteristic "citrons" and deeply staining oval or bulb types; rods with or without spores, will also be present, but cannot be distinguished from other bacilli. The worker should familiarize himself with the *Vibrio septique* types as they appear in guinea-pigs, as the recognition of "citrons," etc., in the films direct from the patient affords a valuable and very rapid diagnosis. The injection of the fluid from haemorrhagic blisters or other exudate into a mouse or guinea-pig will produce the characteristic appearances if *Vibrio septique* is present, and cultures should be made at the same time in meat.

If the animal test is not available more time should be spent upon the examination of films, as that may afford an immediate indication of the presence of the organism; demonstration of the organism in culture even under favourable conditions would not provide a definite diagnosis

FIG. 5.—*Vibrio septique*, from liver of guinea-pig, showing long filaments, etc. Mag. 1,000.

FIG. 6.—*Vibrio septique*: "citrons" from haemorrhagic blister fluid of patient suffering from gas gangrene. Mag. 1,500.

for some days. The absence of citron forms, etc., must not be regarded as evidence that *Vibrio septique* is not present in the wound. *Vibrio septique* appearing in a wound showing an active condition of gas gangrene should be considered as a serious finding, whether accompanied by *B. welchii* or alone.

SUMMARY.

1. *Vibrio septique* is a saccharolytic organism clotting milk in three to seven days, without putrefactive or digestive reaction on meat or inspissated serum. It is a strict anaërobe.

2. Spores are readily formed upon all media. They are oval in shape, and central or subterminal in position.

3. The organism is pathogenic for man. It is also pathogenic for laboratory animals (rabbits, mice, pigeons, and guinea-pigs) both in pure culture and when mixed with other anaërobics.

4. In the animal body the lesions are a blood-stained oedema and deep red colour of the infected muscles. The organism also infects the blood stream.

5. Characteristic morphological types of the organism are found in the muscles; these are "citrons," club and bulb-shaped forms, as depicted in Figs. 2-4, and 6. On the peritoneal surface of the liver long snake-like filaments and chains are formed; these are specific to the *Vibrio septique* type among the pathogenic anaërobics at present known.

6. The citrons and also the deeply staining oval or bulb types may be met with in muscle tissue and in the fluid from haemorrhagic blisters in man in cases of active infection with this organism. This affords an immediate and valuable diagnosis, but a failure to find these types does not constitute evidence that the case is free from an active infection with *Vibrio septique*.

APPENDIX.

Casein Digest Medium.¹

To a 2-litre flask containing 1 litre of tap-water add 20 grams of anhydrous sodium carbonate. Transfer the flask when boiling to a water-bath and add 200 grams of casein, dusting this in gradually to avoid the formation of lumps; then place the mixture in a large Winchester quart bottle, allow to cool down, and add 3 grams of pancreatin with 15 c.c.m. of chloroform. Incubate at 37° C. for five days, shaking vigorously from day to day to break up the crusts that have formed, then add 3 more grams of pancreatin and incubate for ten days longer. After fifteen days' digestion in all the mixture is treated with 400 c.c.m. of N/1 HCl, steamed for thirty minutes to drive off the chloroform, and then filtered. The filtrate is treated with 120 c.c.m. of N/1 NaOH, and its reaction is adjusted to PH = 7.3, using either the hydrogen electrode or phenol-sulphonaphthalein as an indicator in a Marriott scale. The resulting stock broth is diluted with two parts of 0.5 per cent. NaCl in tap-water before use, the reaction being again adjusted if necessary.

The sugars required can be added to this.

Serum Agar Sugar Medium.²

Ordinary agar 75 c.c.m., sterile serum 25 c.c.m., litmus solution 5 c.c.m., to which 1 gram of the required sugar has been added and sterilized by steaming. The medium is made up as for ordinary serum agar.

TREATMENT AND PROPHYLAXIS OF MALARIA.

BY

COLONEL C. A. JOHNSTON, C.B., I.M.S.

A good many articles on the subject of the treatment of malaria have appeared recently in medical journals,¹ evidently because many men suffering from this disease have been invalided to Europe as the result of the war. A certain amount of apprehension must be felt as to the after-effects of some of the lines of treatment advocated. Time and experience can alone settle the questions raised, but, as a contribution to the subject, I desire to draw attention to a memorandum I wrote for the P.M.O., H.M. Forces in India, in 1901, on the use of hypodermic

injections of quinine in malaria. The method (which was described in a review of the memorandum published in the *BRITISH MEDICAL JOURNAL* of March 29th, 1902, p. 793) has stood the test of time and experience. Since writing that memorandum (about seventeen years ago) I have had no reason to deviate one iota from the dicta I then laid down. Other medical men who have made independent observations on these statements of mine have corroborated them.

As I have had uniformly good results from this treatment, I think it will be useful to give a summary of it, for it seems to have dropped out of mind. I must in the first place strongly insist that the technique for the hypodermic injection must be carried out as laid down, otherwise grave results may occur. It must not be thought that quinine injections can be given hypodermically in the same free and easy way as a hypodermic injection of morphine. In the second place, I wish to make it clear that I do not recommend intramuscular injections, but hypodermic, that is, below the *cutis vera*, and above the fascia of the muscles.

Requirements.

1. An all glass 20 m hypodermic syringe with stout needles, thoroughly sterilized.
2. Saline solution 0.5 per cent., sterilized.
3. A wide-mouthed test tube about 3 in. long, sterilized.
4. Carbolic oil 5 per cent. and some cotton-wool.
5. Pure quinine bisulphate 4 grains.
6. Spirit lamp.

Method of Subcutaneous Injection.

Prepare the patient's flank between the iliac crest and the last true rib by cleansing with soap and water, and then smearing with carbolic oil on wool (I do not like tincture of iodine if it can be avoided).

(a) Put the 4 grains of quinine bisulphate into the sterilized test tube.

(b) Fill the syringe with the 0.5 per cent. saline solution; squirt this into the sterilized test tube to dissolve the quinine powder.

(c) Heat the quinine solution in the spirit flame till it comes to the boiling point.

(d) Fill the syringe with this boiled quinine solution.

(e) Dip the needle into the carbolic oil.

(f) When the solution cools down to about 100° F., pick up between finger and thumb of left hand (with carbolized cotton-wool intervening) a good lump of the *cutis vera* in the flank; plunge the needle in up to the hilt (eyelet downwards) into the subcutaneous tissue; sweep the point of the needle from side to side through the connective tissue, describing the arc of a circle, thus breaking down any small trabeculae, and freeing the point of the needle from any fat globule it may be in, and then inject all the solution into the space thus formed; withdraw the needle quickly; massage the flank with the carbolized cotton-wool to disseminate the fluid as much as possible.

If the above directions are carried out properly, I guarantee that the patient does not feel the uncomfortable sensation of burning or pain; and, strange as it may appear, many of my patients never know when the injection has begun or when ended; in fact, the only remark they make is that they felt me pinching up their skin!

The injection is to be given—the method described being strictly observed on each occasion—once daily for five consecutive days in alternate flanks. In addition, $\frac{1}{10}$ grain arsenious acid should be taken by the mouth, and also 5 grains (only) of quinine well diluted, in the early morning daily; the arsenious acid and the quinine should be continued for a month.

The treatment described is all that is required for an uncomplicated case of malaria, but the complications of malaria may be manifold, such as congested liver and disordered action of stomach and bowels, with loss of appetite and constipation. Measures for the treatment of these conditions on ordinary lines should be taken, but must be regarded as adjuncts to what I call the specific treatment by hypodermic injections of bisulphate of quinine.

For chronic relapsing cases of malaria, with enlarged spleen and liver, the same specific treatment is undertaken, but the five hypodermic injections are repeated every fortnight (together with local treatment of the "ague cake" spleen, by counter irritation producing a mild splenitis, etc.) till the spleen or liver becomes normal.

An important point to which I wish to draw attention is not to overdose the patient with quinine by the mouth, thereby upsetting the digestion and ruining any benefit he

derives from assimilation of his food, which gives him a chance of building up his natural resistance to infections generally, whether malarial or other. It should be remembered that the malarial patient has been robbed of a good deal of his haemoglobin by the parasite, and this has to be replaced by his own metabolism; therefore his *primae viae*—liver and other organs—should be given a chance of doing their duty, and his digestive system should not be upset by heroic doses of quinine by the mouth. It serves no useful purpose, but only intoxicates the patient and every tissue of his body, and does not produce the full parasitocidal action of quinine, weight for weight, against the malarial protozoon.

For the information of general practitioners and accoucheurs I may state that quinine given by this hypodermic method can be safely administered to pregnant women—at least that is my personal experience of many cases, and I have never heard of any untoward event in such cases in the hands of any medical man who has used it in India.

I have never advocated the intramuscular injection of quinine, for the big doses used produce local necroses (so-called cold abscesses) in the muscle; this statement has recently been verified by Major MacGilechrist, I.M.S.,² by a *post-mortem* examination of a case fatal thirty-six hours after such an injection (11 grains of quinine bilydrochloride) into the gluteal muscle. This case serves as an object lesson to those who advocate the administration of quinine by intramuscular injection.

I saw many cases of cerebral malaria in the German East African campaign in the field far remote from the base hospitals (some of them mistaken for cerebro-spinal meningitis), and most of these cases recovered when treated on the lines recommended by me, by hypodermic injections. I have no doubt the intravenous method, as recommended by Sir Leonard Rogers, would produce just as good results, but it is not practicable for sections of field ambulances to carry about the more elaborate equipment for intravenous saline injections, in preference to the simpler and safer equipment for hypodermic administration, especially in the bush of Africa and similar terrain.

Prophylaxis.

As regards the prophylaxis of malaria, I held, as do many other medical men, that the daily dose of quinine is not a prophylaxis against malaria; recent investigations and experiments on this question by Lieut.-Colonel Anderson, I.M.S.,³ on gael populations, showed that quinine as a prophylactic was useless and a distinct waste of public money, for the price now of quinine is enormous.

From a scientific point of view I ask this question: "If you state you are sterilizing a medium (that is, cinchonizing the patient's blood) in order to prohibit the growth of a parasite by daily dosing with quinine, and then find that, after all, this parasite does develop in this medium (through some specially enlisted resistance on the part of the parasite to its environments or any other explanation you like), how are you now going to kill (sterilize) by medication this parasite that has learnt to grow in this cinchonized medium? Are you going to increase the cinchonization of the medium by adding more quinine, and thereby teach the parasite to resist further and remain dormant in this medium till such time as he can regenerate?" Obviously the answer is in the negative. Then why do it? For this is the cause of chronic and relapsing malaria, in my opinion; so the only option apparently left to the physician to cure the case is to poison both patient and parasite by heroic doses of quinine and develop in him some other chronic ailment the result of quinine poisoning, the commonest of which is permanent deafness.

Of course it is understood that occasionally cases of malaria gravidarum occur which have to be tackled heroically to save life, but such cases are not now being considered.

The views here stated will, I know, be criticized by those who advocate doses of gr. xv to xx once weekly on Saturdays, or bi-weekly, on the grounds that they have not thereby "cinchonized the media," but have by this means caught the young parasites already there which would ultimately fulminate into a recognized attack if they were not killed. If this theory is right, and really represents what has actually occurred, then of course the answer is that the

dose of quinine given has been not a prophylactic but a curative dose, and if no malarial outburst occurs an actual infection of the parasite in the medium (blood) has been inadvertently sterilized. But prohibition of the infection, which is prophylaxis, has not been accomplished. Moreover this method (gr. xx once a week) has not kept people immune against malaria, and has therefore failed as a prophylactic.

A further criticism I have heard is contained in the theory that although quinine given prophylactically does not actually immunize the patient against an attack, yet it modifies the toxic action of the parasitic infection, so that only a mild attack is produced—as an anti-typhoid injection acts as a prophylactic. Against this theory I advance my practical experience in the East African campaign. I have never seen so many cases of cerebral malaria, haemoglobinuria (blackwater fever), in all my twenty-eight years' experience in the tropics as I saw in East Africa, yet every one who could was taking quinine prophylactically.

Finally, the only prophylactic medication against malaria for armies in the field, in my opinion and experience, on the ground of practical politics, is arsenious acid $\frac{1}{2}$ gram daily, thereby keeping up the natural resistance of the body generally against many ills, not only malaria. There need be no fear of the cumulative action of arsenic, for the troops very often do not get access to the drug, and a break from the drug can always be arranged for one week every month if necessary. It is easier to stop issuing a drug than to supply it regularly.

A golden rule for tackling the question of malaria for the armies in the field is "arsenic as a prophylactic and quinine as a curative only." Yet this is no new precept, for the Italians have done this years ago.

EPIDEMIC POLIOENCEPHALITIS.

(SO-CALLED EPIDEMIC BOTULISM.)

BY

CHARLES H. MELLAND, M.D.LOND., M.R.C.P.,

ASSISTANT PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

PART II.

IN considering the nature and cause of the present epidemic of cases, many of them presenting paralysis of cranial nerves, which in a recent contribution to this JOURNAL I have designated as polioencephalitis, it is well to bear in mind—in view of the fact that they have been so widely referred to as cases of botulism—that somewhat similar symptoms may occasionally be the result of diverse causes. In both botulism and polioencephalitis paralyzes of cranial nerves are features in common, and Van Ermengem, in his classical paper on the outbreak of botulism in Ellezelles, lays stress upon this point. He states that "in the absence of the previous history" (of poisoning having occurred), "it is impossible to distinguish with certainty cases of botulism from bulbar paralysis (Erb's syndrome), subacute polioencephalo-myelitis, and certain ophthalmoplegias."

Polioencephalitis.

Everybody who has paid attention to the subject now recognizes that there exists an acute primary specific disease affecting the grey matter of the brain, of which sporadic cases are not uncommon. This malady, known as cephalitis or polioencephalitis, was first described by Strümpell in 1884, and, in the form which not uncommonly leads to the development of spastic hemiplegia in young children, is fairly familiar. It is comparable with acute anterior poliomyelitis (infantile paralysis), and, like that disease, often occurs in children, is of acute onset and tends towards recovery. It may or may not be associated with such general symptoms as fever, convulsions, headache, stupor or loss of consciousness, or pronounced irritability. The special symptoms produced by the disease depend, of course, upon the particular region of the grey

matter of the brain involved. For example, polioencephalitis *superior*, which affects the nuclei of the cerebrum and cerebellum, may give rise to marked mental changes, coma, hemiplegia, diplegia, and ataxia, while polioencephalitis *inferior*, which affects the nuclei of the pons and medulla, may cause paralysis of one or other or several of the cranial nerves, and combinations of the two may be met with.

The evidence, both clinical and pathological, goes to show that these affections of the grey matter, whether of the brain or spinal cord, are in reality one and the same disease, and are due to a single factor. Recent researches have demonstrated that this factor is a living contagium, since it has been shown that the contagion can be conveyed indefinitely from monkey to monkey by inoculation, though the organism, which is so minute as to pass through the Berkefeld filter, has not yet been for certain isolated. The two affections may occur in epidemics, in which some members of the same family may suffer from the spinal and others from the cerebral variety. Indeed cases are known in which such eye symptoms as ptosis, ophthalmoplegia, and pupillary changes have been associated with affection of the spinal cord, and the combined condition has been termed polioencephalomyelitis.

Stephenson¹ relates a series of sporadic cases over a considerable period in which affection of the ocular muscles was the most prominent feature, and to his excellent introductory remarks on the nature of the disease I am much indebted. The majority of his cases were in children, and consisted mainly of simple oculomotor paralysis, most commonly of the external rectus alone, but in others of various branches of the third nerve. There were associated symptoms in eight cases out of twenty-eight, such as fits, unconsciousness, sleepiness, and loss of energy.

The cases that have been recently described accord in general with this description, and with that of other writers, of sporadic cases of polioencephalitis, and the case that I saw in 1913, which was generally recognized to be of this nature, would unhesitatingly be classed among the epidemic cases had it occurred in the past few months. One feature in that case, which at first made me distrust the diagnosis of polioencephalitis and favour that of cerebral tumour, was the presence of optic neuritis, but I subsequently found that this, though not a common feature, yet was occasionally met with in polioencephalitis, and it is paralleled by two, at any rate, of my present series. Most of the cases are subacute, the paralysis mostly develops suddenly, but in several certain phases of the paralysis were delayed for days or even weeks. The pupils have not been dilated, nor has there been paralysis of accommodation in any of my cases.

Botulism.

Now with this picture of polioencephalitis let me compare that of botulism, mainly relying on Van Ermengem's description.² In his cases, which occurred after eating an infected ham (raw after the foreign fashion), there was a sudden onset of symptoms after a period of twelve to twenty-four or at most thirty-six hours. These consisted of thirst and a feeling of constriction of the throat, soon followed by paralysis of accommodation and other ocular paralysees. The paralysis for near vision and the dilatation of the pupils were constant symptoms, and double vision, squint, and ptosis, were usually met with. In the more severe cases difficulty of swallowing, or inability, supervened, with loss of voice, constipation, and retention of urine. Fever and disturbance of sensation or consciousness were absent, only in the very last stage of fatal cases did coma or a mild delirium develop. The fatal cases were characterized by gradually advancing respiratory and cardiac failure due to progressive bulbar paralysis. About one-third of those who had eaten the poisonous food died in a few days; another third, after more or less severe symptoms, got well; the rest, who had only taken very small amounts of the infected flesh, remained free from symptoms. In those that recovered the ocular paralysis began to improve after two to three weeks, though in some it was several months before the paralysis of accommodation got completely well. The general weakness, which was a characteristic feature, also took several weeks to recover.

Differential Diagnosis.

The likeness between the two conditions rests upon the occurrence of ocular paralysis in each, particularly the double vision, squint, and ptosis. Apart from this striking feature difference outweighs resemblance. In botulism the onset is sudden, with urgently acute symptoms coming on after partaking of some often definitely recognizable poisonous article of diet. There is dryness and a sense of constriction in the throat, with dilatation of the pupil and loss of accommodation; there is great bodily prostration but no psychical change, and there is early death or early cessation of the acute symptoms with slow convalescence. In the cases in this epidemic and in other cases of polioencephalitis these features are in the main wanting. The onset is either subacute, or the development of the paralysis may be spread over several days, or even weeks. There is no feeling of constriction of the throat, no dilatation of the pupil, no loss of accommodation. There has been little bodily prostration in the cases I have seen, except in those cases of polioencephalitis *superior* in which the grey matter of the cortex is involved, when it is associated with psychical changes—sleepiness, lethargy, coma, and delirium—which are absent in botulism. The majority of cases recover; if not, the fatal ending comes after a course of two or three weeks or more, though occasionally earlier.

But the most striking difference lies in the mode of occurrence of the outbreaks of the two conditions. In botulism, almost without exception, the disease occurs in groups, varying in their numbers but including most of those who have partaken of the infected food. Since sometimes the infection of the food is limited to certain parts, those who eat of the non-infected parts may escape; but though the groups may thus be diminished in size it remains true that botulism, as hitherto recorded, is a "group infection." On the other hand, it is notable that in the present epidemic in no instance, so far as cases have yet been published, has any group infection occurred. The cases have been widely scattered, sometimes two in the same neighbourhood, but no two even in any instance in the same house. This might be thought to prove too much, since it might be supposed to disprove the infectious, and hence infective, character of the disease. But it is well recognized that epidemics of other diseases commonly show similar features. It is often very difficult in the case of diphtheria, enteric fever, or cerebro-spinal meningitis to trace the mode of infection in the numerous scattered cases that constitute an epidemic, but it is now proved that the symptom-free carrier or the individual with minimal and unrecognized symptoms plays an important part in such diffuse epidemics. Polioencephalitis in its epidemic form is known to fall into the same category; and such, I take it, is the true explanation of the apparently unrelated cases in the present epidemic. It is a truism of epidemiology that if the movements of contacts are only worked out with sufficient care and thoroughness, indirect connexions between apparently isolated cases in epidemics of the above diseases can almost always be established.

It is probably true that during the last few months, during which the supply of fresh meat has been so greatly restricted, more tinned food has been eaten in this country than ever before. That tinned food may occasionally become accidentally infected with the *Bacillus botulinus* is a well-known fact, but, as I have argued, the incidence of this epidemic is quite different from the incidence of such attacks of botulism as would thereby be produced. The only conceivable way in which such a distribution could occur would be on the supposition that there was a widespread infection of tinned food with a bacillus of attenuated virulence. In such a case there might be extensive ingestion of small doses of its toxin so small that only those with special susceptibility to its action, or those who ate specially freely of tinned food, showed symptoms of poisoning. This is exactly what is met with in ergotism, in which widespread epidemics may occur, due to poisoning of the bread with the ergot of rye, and in the slighter epidemics, when the degree of contamination is low, the disease may pick out sporadic victims in the midst of general immunity. However, though I mention this possibility, there is no reason to suppose that it represents the facts of the present epidemic, since, so far as investigation has gone, there is no evidence at present of any widespread or even occasional

infection of tinned food with *B. botulinus*. Moreover, certainly one of my patients has disclaimed ever having taken tinned food at all; and its relative infrequency among soldiers from abroad who have lived very largely on tinned food is significant.

Prognosis and Treatment.

It remains now to speak of the prognosis and treatment. In the majority of cases recovery occurs, though there is more likelihood of a fatal termination in those cases of the *superior* type; even here, however, recovery may quite unexpectedly take place. But what is of importance is that we are able to hold out to the patient's friends the possibility of recovery from a condition which, but for our knowledge of its nature, we should otherwise regard either as absolutely fatal or as the commencement of a chronic incurable disease, since different cases may simulate cerebral tumour, tuberculous meningitis, or the onset of disseminate sclerosis. The recovery from paralysis may be incomplete, as in poliomyelitis; it is too soon to speak for certain of this in the present epidemic, but some, at any rate, have made a full recovery.

Treatment seems to have little influence on the course of the disease, but, as in poliomyelitis, we should resort to complete and absolute rest in the dark, with or without the use of bromides or other nerve sedatives, during the stage of onset. Urotropin has been given, from a belief in its antiseptic effect on the central nervous system, and salol for a similar action on the nasopharynx, by which route infection is supposed to reach the brain. Lumbar puncture should be performed and, if necessary, repeated in cases which show the more marked signs of intracranial pressure, such as severe pain in the head, vomiting, and unconsciousness. Later, tonic treatment, such as iron, arsenic, strychnine, and cod-liver oil, with fresh air, are likeliest to restore the vitality of the damaged nerve centres.

THE "THICK DROP" METHOD FOR THE DETECTION OF SCANTY SPIROCHAETES IN THE BLOOD.

BY

IL. M. WOODCOCK, D.Sc.LOND.,

(ATTACHED R.A.M.C.)

(From the Military Laboratory, Jaffa, E.E.F.)

In the majority of cases of Palestine relapsing fever (among British troops) which have come under my notice the spirochaetes have been throughout present in the blood in very scanty numbers. This has entailed a prolonged search before the diagnosis could be established; frequently a negative finding has had to be returned, as films cannot be carefully scrutinized in their entirety when a large number have to be examined. On several occasions the spirochaetes have first been demonstrated, after considerable search, at the second or even third time of examination of the particular case.

I have therefore made use of the "thick drop" method, which has proved of much service, not only saving time, but also frequently enabling me to report as relapsing fever, cases in which the examination of an ordinary blood film yielded no result.

To prepare a thick drop for examination, a small drop of blood is placed upon a clean slide. The drop should be about as large as is required for making a good-sized smear and should be spread out a little (with the needle) so as to cover an area about $\frac{3}{8}$ in. in diameter. Too thick a drop is not an advantage, as it is difficult to lake (dehaemoglobinize) completely, and more fibrin is present. The drop must be allowed to dry thoroughly, and before proceeding to lake it, may be gently heated by passing it over a flame two or three times.

There are several well-known methods of laking the thick drop. I have made use of two: (a) Distilled water, or (b) acidulated methyl alcohol.

(a) A few drops of distilled water are poured upon the thick drop, and the slide is gently agitated to and fro. The water may be renewed until the blood has completely lost its colour.

The process takes four or five minutes, depending on the thickness of the drop.

(b) Methyl alcohol acidulated is used in the proportion of 10 or 12 drops of HCl to 50 c.cm. of methyl alcohol; the procedure is the same as in the former case, but the laking takes rather longer. After the colour has been extracted, the drop is well rinsed with distilled water and dried.

Dehaemoglobinization is more complete and rapid by the former method, and there is less formation of fibrin. But unless the greatest care is exercised, the drop, or portions of it, are apt to be removed from the slide, in spite of complete drying (as there has been no proper fixation previously). If distilled water is used, and the preparation is to be stained by gentian violet, it is advisable, after carefully draining off the water when the laking is complete, to pour on a few drops of methyl alcohol, for a minute or two, to fix the preparation to the slide.

The thick drop may be stained by the Giemsa or Leishman method, or with aniline gentian-violet; the last gives excellent results with spirochaetes, the intensely blue-stained parasites standing out well from the surrounding elements. Aniline gentian-violet is used in the proportion of 9 parts of aniline water to 1 part of alcoholic gentian-violet, the stain being left on for twenty seconds or so. The preparation is then well washed with distilled water, by which means the requisite degree of extraction and differentiation can be obtained, and finally dried.

Where examination is desired for suspected malaria or relapsing fever, it is a useful plan to have the slide sent in with both a fair-sized film (extending, say, over two-thirds of the slide) and a thick drop (on the other third) upon it. For staining, the smear can be separated from the drop by drawing a line with a grease pencil across the slide, between the two. The smear is stained by the Giemsa or Leishman method, and if no malarial parasites are found, nor spirochaetes quickly seen, the thick drop is used. If it is desired to examine the drop also for scarce malarial parasites (for example, crescents) as well as spirochaetes, the second method of laking is to be preferred, as distilled water is very liable to disintegrate malarial parasites; and in this case the Giemsa or Leishman method must be used for staining.

INTERNAL DERANGEMENTS OF THE KNEE-JOINT.

BY

H. BRAMWELL, T.D., LIEUT.-COLONEL R.A.M.C.,

DIVISIONAL SURGEON, MILITARY HOSPITAL, TIDWORTH.

DURING the past eighteen months several patients have been sent to the Military Hospital, Tidworth, on account of painful cicatrices on the inner side of the joint. In all cases the cicatrices were the result of linear incisions down the inner side of the joint in line with the patella and ligamentum patellae, over the prominent part of the internal condyle. The history was of an operation performed for some internal derangement of the joint. This has been especially noticeable in cavalrymen.

Since September, 1916, it has been found advisable to segregate the knee cases, owing to the large number, principally the result of football accidents, but at one time a number of injured knees followed trench training. There has been on an average at least twenty cases in hospital daily suffering from derangements of the knee-joint the result of injury.

They practically all suffered from traumatic synovitis, some simple, the others with complications.

The most frequent complications were:

Firstly: Rupture of some fibres of the internal lateral ligament, indicated by acute pain on pressure over the inner side of the internal condyle.

Secondly: Looseness with partial or complete dislocation of the internal semilunar cartilage, indicated by pain on pressure over the site of the anterior end of the cartilage, inability to completely extend the joint, and a history of "locking."

Thirdly: A general stretching of the ligaments was the only objective symptom, besides the synovial effusion. This applied more especially to the posterior cruciate ligament, which is the one ligament of the joint put on the

stretch, both in full extension and full flexion, the latter movement being only checked by the contact of the leg with the thigh.

Fourthly: Loose bodies in the joint, such as chips of cartilage, pedunculated outgrowths, and occasionally pieces of shell.

Treatment.

For simple traumatic synovitis, with marked effusion, probably sometimes haemorrhagic, it has been found that three weeks in hospital is sufficient to enable the patient to be sent as a convalescent for a short period of gentle exercise with massage if necessary. Cases with internal complications have required longer. Out of the total of some 550 to 570 cases which have passed through the hospital during the eighteen months, about twenty-five have been operated on. Only men under 40 years of age, with decided symptoms, and likely to be rendered efficient for A 1 class, have been chosen for operation, and only after careful treatment has failed to improve the condition.

Colonel Jones's method of bloodless operation with tourniquet has been used in every case. The incision has been made down the inner side of the ligamentum patellae, to half an inch below the superior margin of the tibia, then curving inwards to a little beyond the outer margin of the internal lateral ligament. The incision is crescentic. A flap of skin is dissected up and wound cloths applied; with a fresh knife a similar flap of the capsule, but slightly smaller in circumference, is dissected up reaching to the anterior lower margin of the internal lateral ligament. This exposes the terminal branches of the anterior internal articular vessels; these are tied, arteries and veins. The synovial membrane is then divided transversely just above the internal semilunar cartilage. This gives a very full exposure of the joint, the crucial ligaments being fully exposed.

When the offending part has been removed, the synovial membrane is stitched with fine catgut, the capsule drawn down and stitched separately, and finally the skin. By this means three layers of tissue in a valvular manner guard the opening into the joint, and the skin incision is well below the internal condyle of the femur and away from all pressure when riding.

Among the cases operated on, in two cases the internal semilunar cartilage was found completely dislocated and lying between the condyles of the femur. In the majority it was the internal semilunar cartilage which was at fault, but in several only pedunculated outgrowths from the infrapatellar pad, or edges of the cartilage, were the cause of the trouble.

This method of operation has proved satisfactory; only one case gave the least trouble, but eventually recovered completely, and the patients have expressed themselves as thoroughly satisfied. Incisions over the condyle of the femur, in whatever direction, always give rise to annoying symptoms afterwards.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TUBAL ABORTION WITH CYSTIC DEGENERATION OF THE OVARY ON THE SAME SIDE.

Mrs. G., aged 25, a healthy woman (2-para; previous labour normal, two years ago), on the morning of August 12th, 1911, felt sick and out of sorts and suffered from dysuria. Towards evening acute pain in the abdomen set in suddenly and she vomited frequently; there was also a show; she thought she was about eight weeks pregnant, having missed two periods. I saw her about 10 p.m., and found her looking rather pale with a rapid (105) but strong pulse, temperature normal. There was a very slight red vaginal discharge; but, as it had really amounted to little all day, and examination showed no signs of unavoidable abortion, I prescribed opium 2 grains. She soon went to sleep, but woke up about 4 a.m. with violent abdominal pain, intense sickness, and an increase of the vaginal discharge. At 5 a.m. I found her suffering acute pain in the abdomen, principally referred to the umbilicus, and the back. Pulse 120, rather small and compressible, but regular; temperature 99°, and respiration 30. Her expres-

sion was anxious, and she said she felt she was going to die.

Examining under chloroform, I found the uterus slightly enlarged, but not quite of the normal size in an eight weeks' pregnancy. It lay in the natural position, but there was a mass behind and to the left, continuous with it and filling a great part of the left pelvic cavity. Extra-uterine gestation was diagnosed, and the patient was removed to the Cottage Hospital. Meanwhile $\frac{1}{2}$ gr. heroin and $\frac{1}{10}$ gr. trinitrin were given hypodermically. Upon opening the abdomen I found the pelvic cavity full of dark blood clot; when this was removed an ovarian cyst was seen about the size of a large orange on the left side, while the left tube curled round behind it with its fimbriated end underneath the cyst. I could find no rupture in the course of the tube, which was almost normal in appearance, but slightly enlarged; upon freeing it from under the cyst I found the fimbriated end much enlarged and broadened out, coated with congealed blood, and oozing slightly. An ectopic gestation had apparently been lodged in the fimbriae and had aborted into the abdominal cavity, but I think the pressure of the cyst lying on the top of the fimbriae had to a great extent prevented the dangerous haemorrhage usual in such cases; in fact no fresh bleeding could be seen until the fimbriae had been freed, and then only a slight oozing. The tube and the cyst were removed, the peritoneal cavity cleaned, and the patient put back to bed. Except for a vaginal discharge containing some membrane (no complete cast came away), which was probably decidual, and which ceased in a week, the patient made an uninterrupted recovery, and left the hospital one month after the operation. The right ovary was also degenerated and of about the size of a large walnut, but as it had some healthy ovarian tissue, I did not remove it. The woman gave birth to a healthy female child thirteen months later. I searched the blood clot carefully, but could not find the ovum; the cyst showed no signs of torsion, and was easily removed.

I think this case of a tubal abortion and ovarian cyst on the same side must be somewhat rare. The evidence seemed to point to the left ovary having been useless as an organ of generation, so that the ovum in this pregnancy must have come from the right ovary to the left tube; the fact that conception took place in the fimbriae almost proves the peritoneal method of transit. I am also persuaded that the pressure of the cyst hindered what might have been a critical haemorrhage. The patient's menstrual history previous to this had always been normal in quantity, of twenty-eight days' type, and four days' duration, and her urine at the time contained no abnormal constituents.

Perrith. ROBERT B. JOHNSTON, F.R.C.S., M.R.C.P.E.

AVULSION OF THE EYEBALL IN BIRTH.

THE note in the JOURNAL of April 6th, p. 415, recalls a case to which I was called by a midwife on April 1st, 1904. The woman, aged 33, had an extremely prominent sacrum, rendering the antero-posterior pelvic diameter very small. In the early stage of each of her two previous pregnancies she had suffered from retention of urine from incarceration of the gravid uterus needing manual replacement. The first child, labour at the eighth month, was delivered alive by forceps; the second—a breech presentation—was still-born owing to delay in getting the head past the sacrum. I found that she had been in labour for twenty-four hours; the vertex presented high up with the occiput to the right. Chloroform was administered and forceps applied at once; after very strong traction the child was delivered with the right eyeball lying on the cheek; the inner canthus was torn, the tear extending about one inch across the lower lid along the margin of the orbit, and the superior oblique muscle could be seen torn away from the trochlear. I replaced the eyeball and put three or four fine sutures on the lower lid and canthus; the wound healed by first intention.

There can, I think, be no doubt that the eye was in this case not injured directly by the forceps, which were applied without difficulty, as the marks of their pressure were quite plain on the left temple and right occipital region. The cheek, which was rather prominent, appeared to have been lodged against the prominent sacrum, and the friction in delivery tore through the skin and

avulsed the eyeball. The boy is now a strong, healthy lad with an outwards and upwards squint, and the eye useless for effective vision though not blind. At a later pregnancy the mother, by the advice of a London physician, underwent Caesarean section and ovariectomy, but unfortunately died about the tenth day from intestinal obstruction.

Burton-on-Trent.

J. H. JOYCE, M.B., B.C.

ABSENCE OF SPLEEN.

THE following case, in which the spleen was completely absent, appears worthy of record:

J. F., of black race, aged 56, male, was admitted to the Public Hospital, Georgetown, Demerara, British Guiana, by Dr. T. B. MacQuaide, suffering from a strangulated right inguinal hernia, on October 8th, 1917. Death occurred on the same day, and at the *post-mortem* examination performed by me the spleen was found to be completely absent; there were no splenuculi to be found, nor was there any splenic artery.

On reference to Adams's *Principles of Pathology*, second edition, I find that at that date, 1911, about thirteen cases only were on record of complete absence of the spleen.

F. G. ROSE,

Government Bacteriologist and Pathologist,
British Guiana.

Reports of Societies.

ETIOLOGY OF TRENCH FEVER.

At a meeting of the Society of Tropical Medicine on May 17th Major BYAM, R.A.M.C., gave particulars of the experiments tracing the infection of trench fever to the louse, carried out, as already announced, for the Trench Fever Investigation Committee, of which Major-General Sir David Bruce, K.C.B., F.R.S., is chairman. As has been shown by previous reports in the *JOURNAL*, the prophylaxis of the disease centres round the destruction of lice. The disease is of considerable importance to the army owing to the invaliding it produces, and may become of importance to the civil population if infected men returned to homes where lice existed. In a paper by McNee, Renshaw, and Brunt, published in this *JOURNAL* on February 12th, 1916, it was shown that trench fever was a distinct disease and that the infection could be transmitted from one person to another by injections of blood. Evidence was also adduced that the infective agent was to be found in the blood corpuscles themselves. McNee and his colleagues were unable to say how the disease was transmitted in nature, but they pointed out that it was either contagious from man to man, or, what they thought more likely, was carried by one of the common flies or parasites found in the trenches. The evidence for suspecting the body louse was conflicting when the Committee took the matter up. Attempts to transmit the disease by means of the bites alone of infected lice proved entirely unsuccessful. The infectivity of the excreta was then tested. Major Byam described a series of experiments in which excreta were collected from entomological boxes containing 576 lice, all of which had been fed on many cases of recent trench fever during the previous twenty-seven days, the last feed being six hours before the time of collection. The excreta obtained were dry and in fine powder. A volunteer having been obtained, a small surface on the outer side of the arm was lightly scarified, so that blood was just drawn. A portion of the collected excreta was dusted into this blood and rubbed up into a paste with a sterilized needle. The scarified area was allowed to dry, and the shirt sleeve pulled down without any dressing. Eight days later a febrile illness, believed to be undoubtedly trench fever, commenced, and a relapse followed on the sixth, seventh, and eighth days. The experiments were repeated on other volunteers, and the conclusion was clear that the excreta of lice fed on trench fever patients were capable when applied to an abraded skin area of producing a febrile illness similar in its relapsing character and general clinical picture to the disease known as trench fever. The disease was transmitted by intravenous injection of the whole blood from one of the volunteers

suffering from trench fever; the unfiltered serum, after being centrifugalized, did not transmit the disease. Experiments with lice known not to have fed on cases of trench fever were negative, so that it was concluded that trench fever is not a disease caused by normal lice. Cultures of the excreta from these normal lice experiments showed what was taken to be the organism described by Jungmann as the organism of trench fever. This diplococcus would therefore appear not to be the cause of the fever. Major Byam summarized the results of the experimental work as follows:

1. The whole blood from febrile trench fever cases up to the fifty-first day of disease, when injected intravenously, was capable of reproducing the disease. *The incubation period in such infections varied greatly—from five to twenty days.*
 2. The virus as contained in the circulating blood was destroyed by the addition of distilled water in large quantities.
 3. The bites alone of infective lice did not produce trench fever.
 4. The excreta of infective lice when applied to a broken surface of skin readily produced trench fever. *The incubation period of such infections was remarkably constant and averaged eight days.*
 5. The excreta of lice fed on trench fever patients were not infective till the expiration of not less than eight nor more than twelve days from the commencement of the feeding on trench fever blood, thus indicating a developmental cycle in the louse or a period during which the organism multiplied.
 6. Once lice were infective they remained so till at least the twenty-third day from the date of their infection.
 7. The virus of trench fever, as contained in infected louse excreta, was capable of withstanding drying at room temperature, exposure to sunlight, keeping for not less than sixteen days, and heating to 56° C. for twenty minutes.
 8. 80° C. for ten minutes destroyed the virus, which was therefore not a spore-bearing organism.
 9. The bodies of infected lice when crushed upon the broken skin were capable of producing trench fever. When lice became so infective remained to be determined.
 10. Infection probably did not take place by the mouth or by inhalation.
 11. The excreta of lice were not normally capable of producing trench fever.
 12. Trench fever infected lice did not transmit the disease to their offspring.
 13. There was a possibility of some attacks of trench fever being afebrile throughout.
 14. The percentage of individuals naturally immune to trench fever was exceedingly small.
 15. Old age was no bar to infection.
 16. Such immunity as resulted from an attack of trench fever was not permanent, and might only persist for so long as the individual showed evidence of the disease.
 17. Even as late as the seventy-ninth day of disease a patient's blood might remain infective, and be capable of infecting lice fed on such a patient while febrile.
 18. The different varieties of trench fever resulted from differences in the persons infected rather than in the source of infection.
- As the experiments had been but few, some of these findings might be modified by future work.

Major-General Sir W. G. MACPHERSON, D.D.G.M.S. France, speaking of experiments carried out in France, said that it had been found that the injection of blood from cases of trench fever produced the disease within one week, and the disease could be carried on through several cases. Lice infected from trench fever cases had been fastened on to the arms of men in such a way that the arm could not be scratched, and trench fever had been produced in these men in three weeks or longer. If clothes were placed in pits in which the temperature was raised to 50° to 70° C., the lice they contained were completely destroyed. Men of a platoon should be freed from lice simultaneously. Powders had proved very unsatisfactory.

Colonel Sir W. B. LEISHMAN, A.M.S., also spoke of the work carried on by the Trench Fever Committee in France. The conclusions arrived at were similar to those of Major Byam. The incubation period in France in the case of inoculation directly from man to man was five to seven days. The period was longer when the blood was taken later in the disease or during relapses. In louse bite inoculation the incubation period was three times as long as in the case of blood inoculation. The organism was probably a protozoon, its cycle of development taking five to seven days. The virus was evidently present in the plasma, as the plasma experiments of the American party were positive in 100 per cent. of cases. This suggested that it was extra-corpuscular, and not connected with the blood cells. The mode of transmission was through the excrement, as shown by Major Byam, but late experiments in France appeared to prove

that infection could be caused from the bite of lice apart from excreta. Dried deposit from the urine of three trench fever cases had been rubbed into a scarified place on the arm, the patient developing trench fever in consequence.

Deputy Surgeon-General T. W. BASSETT-SMITH, C.B., R.N., said that the French had inoculated guinea-pigs with blood taken during the pyrexial period. A form of fever similar to that of trench fever was noticed, and spirochaetes had been found in blood taken from the heart during a period of slight rise of temperature. The spirochaetosis was allied to other forms; the immunity reaction was not the same as that of ictero-haemorrhagic fever.

Colonel G. SIMS WOODHEAD, R.A.M.C., asked how long the food material in the blood took to pass through the alimentary canal of the louse, and whether any experiments had been carried out by injecting bone marrow or fluids from it. The organism appeared to carry on its pathological work in the blood, bone marrow, spleen, and sheaths of blood vessels. There seemed to be evidence that the sympathetic system was especially involved, as evidenced by the vomiting, disordered action of the heart, and pyrexia. The myalgia appeared to be referred pain due to excitation of nerve cells in the spinal cord.

Captain ARNOLD RENSHAW, R.A.M.C., said that in twenty cases the bone marrow had been examined but no spirochaetes or any parasites had been found. The hole drilled in the bone marrow promptly relieved pain, which was probably due to pressure.

Major BYAM, in reply, said that food took about three hours to pass through the alimentary canal of the louse and was excreted at the next feed. Experiments showed that the poison appeared to affect the vagus system, and later the sympathetic system. "Referred pain" had been relieved by tapping the spine.

Reviews.

POLIOMYELITIS.

THE prevalence of acute poliomyelitis in America, and especially the great epidemic of 1916 in New York, has stimulated much investigation into the epidemiology and etiology of this disease. Flexner and Noguchi's description of globoid bodies as the causal factor was received with some doubt, and Rosenow and others argue in favour of a streptococcal origin. With this conflict of opinion in mind, it is interesting to compare the views expressed by RUHRÄH and MAYER¹ in their recent work on poliomyelitis in all its aspects with those of Draper of the Rockefeller Institute for Medical Research, whose monograph on the subject was reviewed in our issue of February 2nd, 1918 (p. 152). The two works were published almost simultaneously, and agree on the important etiological questions that the globoid bodies are the most probable causal factor, and that the disease is primarily a general infection which may, but often does not, attack the central nervous system. Ruhräh and Mayer make full use of the work of the Rockefeller Institute, and quote the results of the inquiry made into the epidemic of 1916. The object of the authors, indeed, has been to collect into one volume, from the enormous and ever-growing literature of the subject, the information they themselves wanted. In the chapter on the history of the disease the title-page and a number of figures from Jacob von Heine's monograph of 1840 are reproduced; the earliest mention of the disease as now understood is given from Underwood's *Diseases of Children* in 1784.

The authors adopt the classification of the scheme of the New York Health Department, distinguishing the abortive or non-paralytic, the rare ataxic group, the cortical, and the ordinary spinal form, the last including the meningitic, bulbar, bulbo-spinal, polyneuritic, and ascending varieties. The question of the relation of Landry's ascending paralysis to poliomyelitis is well considered; the conclusion reached is that most of the cases regarded as Landry's disease are poliomyelitis, although other conditions may possibly give rise to the same clinical picture. A special feature of this valuable handbook is the detailed account of the treatment,

especially of the exercises; this part is successfully illustrated by numerous photographs. The authors have certainly produced a most useful work.

APPLIED BACTERIOLOGY.

DR. BROWNING and his collaborators of the Bland-Sutton Institute of Pathology have gathered a fund of useful and original information in the realms of present-day bacteriology within the pages of a small volume with the title *Applied Bacteriology*.² Perhaps the most important single subject dealt with is the brilliant-green-telluric-acid method for isolating organisms of the enterica group, a method resting upon a firm basis of experiment, and adopted with success by other bacteriologists. Dr. Browning quotes an instance in which this method yielded a pure culture of typhoid bacilli from a mixture of two typhoid bacilli with 2,800 other viable organisms. The brilliant-green inhibits the ordinary colon bacilli and the telluric acid the inositol-fermenting group of organisms, both of which are bug-bears of the bacteriologist when making examinations for organisms of the enteric group. It is a pity that Ebrlich's rosindol reaction has not been more widely applied to save both time and expense in the differentiation of lactose non-fermenting organisms. It is, however, quite likely that the brilliant-green method is the best for its purpose; it has been worked out with meticulous accuracy by Dr. Browning and his collaborators. The Widal reaction after inoculation, upon which Mackie and H. G. Wiltshire did invaluable work, is relegated to a minor position in the recognition of enterica organisms, partly on the ground that inoculation agglutinins largely overshadow pathological agglutinins. The "absorption" method is recommended as being more accurate. Accurate measurement is preferred to Dreyer's method of counting drops, and the calibration of pipettes is carefully described.

Dr. J. F. Smith of Glasgow contributes two useful chapters, one on the bacteriological identification of diphtheria, and the other upon the uses of telluric acid in isolating diphtheroid germs and streptococci. The suppression of the *Bacillus pyocyaneus* and the *Urobacillus septicus* by thallium acetate is likewise a discovery of considerable practical value. The chapter on coloured antiseptics strikes new ground. Proflavine and acriflavine are held to be the most effective antiseptics in the presence of serum, and thus to be more powerful than the halogen group, such as chloramine-T. Their use is recommended both generally in sepsis and for turning the scale in early septic peritonitis. The Rideal-Walker antiseptic coefficient is deprecated on the valid ground that it holds good only for short periods of time. Ultra-violet radiation has not been found by Russ and others to possess a practical differential antiseptic value, as Dreyer formerly believed. The Abderhalden reaction in pregnancy is also discredited.

The antibody content of the blood, it is maintained, is not necessarily a gauge of the degree of immunity; this view is at first sight a trifle disconcerting, but it may conceivably be due rather to failure to detect the antibodies than to their absence. The specificity of antibodies of the colon group of organisms, a fact inferred by Emery and other workers in vaccine-therapy, is here established by the result of careful experiments.

The final chapter, on tetanus, contains much of clinical interest, and is very complete. The remainder of the book is purely bacteriological. We rather deplore Dr. Browning's poor opinion of the "crude mass of British (tetanus) statistics," amongst which, in point of fact, Golla's are a model of careful analysis. Dr. Browning wisely emphasizes the importance of giving antitetanic serum intravenously as well as intraspinally in early developed tetanus, the subcutaneous route being too slow in these cases to be effective. That certain horses may be "carriers" of tetanus is a fact which will be novel to many.

This book will be of great practical value to the bacteriologist, but is rather beyond most clinicians or administrators, to whom it is also inscribed. It is based upon a rich fund of well-digested facts.

² *Applied Bacteriology: Studies and Reviews of Some Present-day Problems for the Laboratory Worker, the Clinician, and the Administrator*. Edited by C. H. Browning, M.D., D.P.H., with contributions also by W. Gilpin, R. Gullbransen, T. J. Mackie, S. Russ, J. F. Smith, and L. H. D. Thornton. London: Henry Frowde, and Hodder and Stoughton, 1918. (Cr. 8vo, 291 pp.; 4 illustrations. 7s. 6d. net.)

RADIOGRAPHY OF THE SKULL.

In his *X-Ray Atlas of the Skull*,³ Dr. RUSSELL GREEN points out that bony landmarks are so numerous, and vary so much according to the angle at which a radiograph is taken, that the correct interpretation of skull radiographs is a very difficult matter. To overcome these difficulties of reading he has made radiographs of a dry skull from various angles, and has increased the opacity of certain parts by devices such as outlining sections with wire, covering structures with tinfoil, injecting sinuses with bismuth paste, and so on. Confining these processes to one side and then making a radiograph, the result affords a definite elucidation of the meaning and cause of the radiographic appearances.

The *Atlas* consists of a large number of very beautiful plates of these radiographs, showing on the one side the usual x-ray shadows and on the other side the various areas differently coloured. Across each coloured area is printed the name of the bone responsible for the shadow. Each plate shows also a photograph of the head, and of a skull, in the position in which the radiograph is taken.

The work is the result of the author's difficulties whilst attached as an x-ray expert to a large military hospital; and it was undertaken in order to make the localization of foreign bodies in and about the skull a certain and easy proceeding. He claims that the only additional apparatus required is a pair of compasses and a millimetre rule; and that, given good lateral and antero-posterior skiagrams, it is possible to give a definite opinion as to the relation of a foreign body to some salient bony point. In addition to a full description of each plate, the *Atlas* contains a short but concise description of the special radiographic apparatus required, and the author's method of marking the skin spots, as well as a table for reading off the distance of foreign bodies from the plates where a constant distance of 50 cm. from target to plate and a constant tube shift of 10 cm., are used.

Apart altogether from the mere localization of foreign bodies, the series of diagrams set out in this manner should be a valuable addition to the library of every expert x-ray worker, as affording an easy and rapid means of reading off the various shadows and areas in any given radiograph of a head.

"NEWEST TREATMENT."

THE *Handbook of Practical Treatment*,⁴ described as a volume on "the newest treatment," is supplementary to the work which began to appear in 1911 under the guidance of the late Drs. J. H. MUSSEN, sen., and A. O. J. KELLY, two enthusiastic physicians who unfortunately rest from their labours, though the editorial names remain the same. The reader is here presented with accounts of new developments in treatment since the original articles were written, and as a natural result some of the articles are quite short. Others, however, have been rewritten or are quite new, and special mention may be made of Surgeon-General W. C. GORGAS's contribution on yellow fever, Drs. R. COLE and CHIEKERING's account of typhoid fever, Dr. T. JANEWAY's review of the modern treatment of diabetes, Dr. ROWNTREE's description of renal therapeutics, and of Dr. HOMER F. SWIFT's account of auto-salvarsanized serum in cerebro-spinal syphilis. Drs. W. H. PARK and C. KRUMWIDE, jun., have written a clear and sane article on vaccines and serums, and there is an admirable account of the specific therapy of pneumococcus infections by Dr. A. R. DOCHEZ, dealing with antipneumococcus serum, the result of vaccines which he finds do not carry conviction, and ethylhydrocuprein, called optochin for short and trade purposes, which has an encouraging future but the drawback that it may cause temporary blindness and deafness. The only British contributors are the late Sir LAUNDER BRUNTON and Sir CLIFFORD ALLBUTT, who from his ripe experience pleasantly discusses the present state of our knowledge about digitalis, summarizes his experience of the soldier's heart, and says of angina pectoris that, whatever view be taken of its nature, it should be treated

on the lines of aortic aneurysm, by complete rest in bed for some weeks or months. In conclusion, it may confidently be said that this work fulfils its promise.

NOTES ON BOOKS.

WE have received the thirty-fourth issue of the *Year Book of the Scientific and Learned Societies*⁵—a most useful work of reference compiled from official sources. While a few scientific societies have been in abeyance during the past year of war, others have come into being, and the number of papers read fell little short of the average of recent years. As usual, a section is devoted to the principal medical societies. We cannot find any reference to the Medical Research Committee, though a list is given of the medical staff of the Local Government Board.

We have inadvertently omitted to mention that the sixteenth edition of Dr. HALE WHITE's *Materia Medica*⁶ has been published and has undergone various modifications to meet new conditions; in particular, it now contains an appendix setting out the various regulations affecting prescribing that have been issued as a result of the war, and attention is very emphatically drawn to the necessity of the reader making himself acquainted with them. The first edition appeared in 1892; the numerous editions that have been called for since then are convincing proof of the practical merits of the book.

Dr. LESLIE THORNE THORNE has issued a new, fifth, edition of his small handbook on *Nauheim Treatment in England*.⁷ The text has been rewritten, and the book enlarged by the addition of chapters on arterio-sclerosis and high blood pressure, angina pectoris, heart strain, irritable heart and Graves's disease, and one or two other topics. The book is of a practical character, and includes descriptions of the exercises recommended as well as of the baths.

The pictures for Part II of *British Artists at the Front*⁸ are provided by Sir John Lavery, A.R.A., and are chiefly concerned with the naval bases. They include striking sketches in colours of the shipyards and the big ships and the mine sweepers in harbour, but there are some notes of aerodromes and one of tanks in the making, all done with the artist's strong feeling for form.

⁵ *Official Year Book of the Scientific and Learned Societies of Great Britain and Ireland*. Thirty-fourth annual issue. London: C. Griffin and Co., Ltd. 1917. (Demy 8vo, pp. 342. 5s. net.)

⁶ *Materia Medica: Pharmacy, Pharmacology, and Therapeutics*. Sixteenth edition. By W. Hale White, M.D., Lieut.-Colonel R.A.M.C.(T.). 1918. London: J. and A. Churchill. (Fcap. 8vo, pp. xii + 716. 7s. 6d.)

⁷ *The "Nauheim" Treatment, in England, of Diseases of the Heart and Circulation*. Fifth edition. By Leslie Thorne Thorne, M.D. 1918. London: Baillière, Tindall, and Cox. (Cr. 8vo, pp. vii + 160; 92 figures. 5s.)

⁸ London: Country Life, Ltd. 1918. 5s. net.

BRITISH EQUIVALENTS FOR GERMAN MEDICAL SUPPLIES.

I.

THE outbreak of war stopped the ordinary sources of supply of some of the material and appliances used in medicine. The principal disturbance was among the synthetic products derived directly or indirectly from coal-tar. Before the war what are termed "fine" chemicals were largely of German origin, "heavy" chemicals were largely British, though not to the same preponderating extent. Whatever shortage has arisen in "heavy" chemicals has been due principally to Government demands, not to the lack of normally sufficient supplies. In soda salts, for example, which are products of the "heavy" chemical trade, there has been nothing like famine. So far as "fine" chemicals are concerned, the German share in the preparations used in medicine amounted almost to a monopoly, as it did also in photographic developing agents and in many dyes. Even such substances as iron salts, iodine, and cyanide were supplied in part by Continental houses, but in the case of these articles after the outbreak of war the British manufacturers were able to meet demands from their own resources. It was different with some of the very complex compounds. A few synthetic drugs, such as chlorbutol, had been made by British houses in pre-war days, and Franco produced synthetic adrenalin, but among the more important drugs which were, we believe, not manufactured in this country were antipyrin, aspirin, salicylic acid, phenacetin, chloral hydrate, phenolphthalein, saccharin,

³ *X-Ray Atlas of the Skull*. By A. Russell Green, M.B., B.S., Lond., M.R.C.S. Eng. London: Longmans, Green, and Co. 1918. (Med. 4to, pp. 27; 5 coloured plates. 10s. 6d. net.)

⁴ *A Handbook of Practical Treatment*. By many writers. Edited by John H. Mussen, jun., B.S., M.D., and Thomas O. Kelly, A.M., M.D. Vol. IV. Philadelphia and London: W. B. Saunders Co. 1917. (Roy. 8vo, pp. 1000. 30s. net.)

veronal, sulphonal, trional, eucaïne, and novocain, together, of course, with the salvarsan compounds. Most of these were exclusively made in Germany, and the value of the imports of these products was placed at over a million a year. With regard to other pharmaceutical preparations the case was less difficult. For some years opium alkaloids and quinine, and more recently caffeine, strychnine, and emetine, had been produced in this country, some of them on a large scale, even for export purposes, and others, like cocaine and theobromine, in small aggregates; altogether a good many compounds were available. Germany, however, was a larger manufacturer of all these bases except morphine, and it was in Germany that many of the rarer alkaloids were prepared. Atropine, homatropine, and eserine were probably exclusively German.

Under the stimulus of war many British firms started experiments and produced chemicals and galenicals to replace German-made preparations, until, first in respect to one class of products and then to another, the country became self-supporting. A start was made on salicylic acid and its compounds, and one firm was manufacturing salicylic acid early in 1915, and by the middle of 1916 a sufficient supply of salicylates and acetyl-salicylates was assured. This was followed by work on atropine sulphate, which now figures in the manufacturing list of more than one British firm. Among articles previously wholly or mainly of German origin but now produced in this country are absolute alcohol, butyl-chloral hydrate, paraldehyde, lactic acid, homatropine, phenacetin, saccharin, salol, tribromophenol bismuth (xeroform), potassium permanganate, novocain, and salvarsan. A British fine chemical industry has been established, and medicinal products of purely British manufacture now have a wide range, and cover organic antiseptics, antipyretics, sedatives, local anaesthetics, and diuretics. Many of these preparations are not substitutes for the German products if the word "substitute" denotes something different and possibly inferior; they are identical in chemical constitution, and are utilisable for the most part in the same manner and in the same dosage as the products they displace. In some cases they are even better than the original because the standardization is higher; this is true more particularly of the alkaloidal productions. To duplicate the extremely efficient German drug industry is no small achievement, amid all the embarrassments of war conditions, for it has to be remembered that many of the preparations depend upon the by-products and intermediate products of other chemical processes. The achievement was only possible because British manufacturing chemists had been accumulating experience before the war, familiarizing themselves with laboratory equipment, and accustoming their minds to the habit of research. The scientific foundations were already laid, and when the emergency arose the commercial superstructure was quickly added.

The value of this preliminary work was to be proved when, on the stoppage of the German supplies of salvarsan, a licence was granted by the Board of Trade to Burroughs, Wellcome, and Company for the manufacture in this country of these preparations under the name of "khar-sivan" and "neokhar-sivan," and to Poulenc Frères, of Paris, for the sale in Great Britain (through the agency of May and Baker, Limited, of London) of the same products under the name of "arsenobenzol-billon" and "nov-arsenobenzol-billon." In spite of their distinguishing trade names, these products are chemically identical with salvarsan and neo-salvarsan. The licence granted by the Board of Trade was subject to the condition that all samples of the drugs should be submitted to biological tests by an authority approved by the Board; the policy of the Medical Research Committee, the authority chosen, was outlined in the BRITISH MEDICAL JOURNAL of April 10th, 1915 (p. 649), and records of experience in the practical application of the new equivalents have been given in later issues.

In addition to these products, Burroughs, Wellcome, and Company have prepared antifibrin, which was the first of the antipyretic drugs to be discovered in Germany thirty years ago, hexamine, phenacetin, beta eucaïne hydrochloride, and various glycerophosphates, also salts of atropine, cocaine, hyoscyamine, hyosine, homatropine, eserine, pilocarpine, and tropacocaine, all of them previously obtainable chiefly or entirely from Germany. A

further achievement has been the elucidation of the chemistry of the alkaloids of ipecacuanha. The constitutional relationship between emetine and cephaeline has been investigated in the firm's experimental laboratories, and the synthesis of emetine is the direct result. This firm has a materia medica farm at Dartford which seems likely to have an important influence upon the creation of a standard herb supply. Here not only are aconite, belladonna, digitalis, and hyoscyamus grown on a large scale, but experiments with plants other than indigenous are being carried out. It is commonly supposed that the soil and climate of Britain are unsuitable for alkaloid-yielding plants. The difficulty has probably been over-estimated, but in any case, with the resources of the British Empire to fall back upon, there seems no reason why we should not be pharmaceutically self-supporting, and independent of the German syndicates which, while deriving few medicinal plants from their own country, controlled drug supplies grown in various parts of the world. The *Hyoscyamus muticus* of India and Egypt is said to yield 1 per cent. of alkaloid, and the sufficient importation of this plant should be of assistance.

Three interesting products in definite substitution for similar articles previously obtained from Germany have been brought out by Allen and Hanburys. The first of these is thiosinamin salicylate, under the trade name of salicylsin, which is made up for hypodermic injection, and is similar to Merck's fibrolysin. Another of the equivalents brought out by this firm is designed to take the place of bromural. It is brom-iso-valeryl-urea, commercially named dormigene, containing 35.9 per cent. of bromine. Allen and Hanburys have also produced a bacteriological peptone to take the place of Witte's peptone. This product, called eupepton, is a fine, buff-coloured powder, almost odourless, and in the opinion of bacteriologists is equal to the peptone formerly supplied from German sources for the preparation of a nutritive medium. Another manufacturing chemist who has been successful in preparing various equivalent preparations is Dr. W. Martindale of New Cavendish Street, London. Upon his list are chloralamide, bromine, and iodine compounds of albumin, benzonaphthol, and sodium barbiturate (the equivalent of sodium veronal); latterly it has become a question of making organic chemicals directly or indirectly required for war purposes, and among these he names dimethylglyoxine, benzidine, thiosinamin, tribromophenol bismuth, emetine bismuth iodide, phenol-sulphone-phthalein, and others. Along a different line of investigation Dr. Martindale also deserves some credit for introducing a modest industry by the production of compressed moss in sheet form. After twelve months' work in the experimental stages he was able to secure this absorbent dressing, which is specially valuable in view of the shortage of cotton and gauze, in a form equal to, if not better than, the German article, and entirely obtained from British-grown moss.

We cannot attempt to enumerate all the fine chemicals which have issued from British works laboratories during war years. Burgoyne, Burdidges and Company of East Ham have now a list of thirty-four medicinal products which they are manufacturing. These include hexamine (urotropine), calcium lactate, anethol, eucalyptol, cocaine nitrate, and a number of acids and salicylates previously obtained from Germany. A similarly lengthy list, the principal items of which are again hexamine and calcium lactate, and phenacetin, aspirin, and lanoline, as well as salvarsan and neo-salvarsan, is that of Evans, Sons, Lescher and Webb, Limited, of Liverpool.

(To be continued.)

DR. W. HIRSCHLOFF, speaking at a medical meeting at Königsberg, said that the blood pressure was raised after a flight, particularly in men over 30. The amount of haemoglobin and the number of the red cells were invariably found to be increased in men who had been flying for some time. The lymphocytes also were more numerous. Flying provoked no organic changes in the heart other than those associated with athlete's heart. Another speaker suggested that the reason why mountain climbing might induce certain symptoms at an altitude of only 3,000 metres, whereas the airman did not suffer till he had reached a considerably greater altitude, was that the airman had not exerted himself much in getting to this height.

British Medical Journal.

SATURDAY, MAY 25TH, 1918.

PRECAUTIONS AGAINST THE SPREAD OF MALARIA.

It is very well known that malaria used to be endemic in certain parts of England, and although the general belief is that it died out at some time during the last century, it has never been conclusively proved that it might not persist on a very small scale in certain particularly favourable areas. Some seventeen years ago Nuttall, Cobbett and Strangeways, in the course of a survey of certain parts of England, not only found *Anopheles* in districts where ague formerly prevailed, but also in parts as to which they could obtain no record of the disease at any time in the past. They concluded that the occurrence of ague was not so much a matter of the geographical distribution of *Anopheles* as of the numbers present in a district. They attributed the occasional occurrence of ague in certain districts to infection of *Anopheles* by a malarious subject coming from some other country. From that time until military operations took British forces into the near and middle East nothing occurred to direct attention to the subject. Since then it has become necessary for the authorities in England, and also in France, to give attention to the risk of the re-establishment of endemic foci.

Towards the end of 1916 the return of many men invaded with malaria led Sir Alfred Keogh to take steps to obviate the risk, and as a result of conferences with experts it was decided to concentrate soldiers infected with malaria at special malaria hospitals in the United Kingdom. A little more than a year ago Mr. Macpherson was able to state in the House of Commons that centres for the treatment of malaria had then been established in each command, or eight in all, and that officers with experience of the disease had been placed in charge of them. It was anticipated that in spite of all precautions indigenous cases might arise, and this happened in England during the summer of last year, a small number being reported both among the troops and the civil population in the south, but especially in the south-east of the country.

In view of these facts the Army Medical Department communicated with the Local Government Board, and subsequent inquiries have been carried out jointly by the two departments. Preliminary communications were addressed to medical officers of health, and inspections were made. General instructions for the treatment of malaria cases, both in hospital and outside, were issued by the War Office; they were to the effect that all men infected with malaria should be given 60 grains of quinine weekly, and should be provided with bottles of quinine tablets to carry about with them, partly in the hope of preventing relapses, and partly to prevent the spread of the disease from malaria carriers to healthy persons. Soldiers suffering from malaria in places where mosquitos abounded, if they could not be sent to special malaria hospitals or otherwise removed from the district, were collected in huts protected against the entry of the insects. In

the malaria hospitals cases were similarly protected when this was considered necessary, the opinion being that protection from mosquito bites, together with persistent dosing with quinine, would suffice to check the spread of malaria from the military cases in such localities. In addition much work was done in the way of clearing and oiling pools and watercourses. Recent surveys have shown that *Anopheles* occur in small numbers during the summer all through the United Kingdom, but probably, it is considered, usually in such small numbers as to reduce the danger of the spread of malaria to an almost negligible quantity.

Early this year further conferences were held; a new memorandum was issued by the War Office, and several officers, including Captains A. Macdonald, O'Connor, and Parsons, R.A.M.C., and Lieutenant Edwardes, have been put on special duty to visit the most dangerous areas in order to supervise the military measures which have been taken, and to give expert advice and assistance. The Local Government Board has taken steps to ensure that malaria is made notifiable in localities known to be, or thought likely to become, infected. The army has in force a general system for the immediate notification of cases of malaria coming into the United Kingdom from abroad, and records are kept of the ports where such cases disembark and the places to which they go on leave or are stationed when on duty or in hospitals. The civil medical officer of health in an area specially affected can thus be informed when such a case enters his district in order that its subsequent course may be watched. Regular monthly reports sent in by medical officers of all units and military hospitals are collected, tabulated, and studied. The organization now set up provides for the close supervision of all former foci of malaria in England, and if new foci are discovered machinery adequate to deal with the matter is available. In all this the War Office is working with the Local Government Board; the Board's medical department now includes two inspectors who formerly had wide experience of malaria in India—Lieut.-Colonel S. P. James, I.M.S., and Lieut.-Colonel Wilkinson, I.M.S. They are available to give advice on the measures required by the civil authorities.

So far this year no new cases of indigenous malaria have been reported. We understand that the Local Government Board has in preparation a memorandum on the whole subject and that its publication may be expected within the next few weeks.

TUBERCULOSIS OFFICERS AND THEIR WORK.

THE national determination to overcome one great evil in the shape of autocracy and military domination has not had any serious effect upon the other national effort to suppress the unseen but equally deadly evil known as tuberculosis. The army of tuberculosis officers with their assistants of both sexes obtain no mention in the newspapers, and the results of their work can only be judged by the official reports issued for the information of the councils or other bodies by whom they are employed. No great victories can be recorded, but the gradual spread of knowledge and experience into the homes of those who are the unconscious centres of infection, and the gradual weeding out of the dangerous elements, cannot fail to be exercising an influence for good over a very wide area. In most of their reports the tuberculosis officers, especially those working in large towns,

point out the need for closer co-operation between the panel doctors and the tuberculosis centres.

In his report for the borough of Wigan the tuberculosis officer calls attention to the undoubted fact that cases of anaemia, indigestion, wasting and general asthenia are too often glossed over by a soothing diagnosis, although tuberculous in origin. He makes the suggestion that all cases so certified for insurance purposes should be examined at stated intervals at the tuberculosis centre, if certificates are frequently renewed. By such means the true condition might be detected and the high percentage of cases seen for the first time with advanced disease correspondingly lowered. The induction of artificial pneumothorax has been found to be of remarkable value in a few suitable cases without widespread adhesions, and relief has been given which could not have been attained by any other known means. Instances of this are recorded by the tuberculosis officer for the Soke of Peterborough. The results, however, are often disappointing owing to the extreme difficulty of diagnosis of the exact conditions within the thoracic cavity. Even with the best assistance of *x* rays it has not been found possible to avoid occasional mishaps.

The important question of dealing with tuberculous or suspected children in schools is discussed at length in the March number of the municipal report of the Tuberculosis Sanatorium in Chicago, a city in which the whole subject has been attacked very vigorously. Systematic examination has detected a very considerable undercurrent of the disease in family life, wholly unsuspected by the victims and their friends. The assembling of suspected children at a tuberculosis centre, where they are of necessity brought into contact with actual sufferers, is properly deprecated and a system of regular school inspection by tuberculosis officers advocated. Parents do not raise objections to such inspection, which would appear on all grounds to be the more satisfactory proceeding and can be maintained as part of the regular school routine.

Apart from these special points, it must be noted that the same complaint is traceable throughout all the official reports—namely, that notification is too often delayed until the curative stage has been passed. One reason for this delay is to be found in the mistaken idea that a positive diagnosis is not warranted until bacilli appear in the sputum. Much subsequent misery is caused by lack of courage to face unpleasant facts, and if the individual alone were to be regarded he might well be left to take the consequences of his cowardice; but in the case of tuberculosis the interests of the individual must give place to those of the community in which he lives, and his medical adviser, whether he be acting in a private or a panel capacity, should refuse to aid in the suppression of the truth.

THE CONTROL OF THE MEDICAL SERVICE OF THE ARMY.

ONE of the curious anomalies produced by the war is the fact that for the past three and a half years the control of the Army Medical Service as a whole, except in France, has been in the hands of an officer who throughout has been "acting." The reason is that Lieut.-General Sir Arthur Sloggett, the official chief of the service, who took up office as Director-General A.M.S. on June 1st, 1914, has since October, 1914, been abroad in immediate command of the medical affairs of the British armies in France. The regulation term of office for the Director-General of the Army Medical Service is four years, but it has been not uncommon to extend the term by a

further year, and within the next week or two we shall know whether this practice is to be followed on the present occasion or whether the present acting officer, Lieut.-General Goodwin, is to be confirmed forthwith in his appointment as Director-General A.M.S. In either case, however, no change in the directorate of medical affairs in France need necessarily ensue. Sir Arthur Sloggett, we imagine, is far too keen a soldier to desire to lay down his responsibilities until the war is over, and we do not anticipate that the Army Council will invite him to do so, for Sir Arthur Sloggett is one of the Generals who have not only made good, but more than good; his administration, in short, has been characterized throughout by a high level not only of foresight, but also of adaptability to the varying circumstances of the war. Of this point the latest news we have heard from France serves as an apt illustration. An advisory body to control and direct medical research has been created. Progress in medical affairs has all along been rapid in the British army in France, because the desirability of taking full advantage of civilian experience has been thoroughly recognized, and the British medical authorities in that scene of war have made it their duty to see that scientific ambitions shall not be checked more than military needs render absolutely necessary. As a result, an increasing number of medical officers have felt encouraged to endeavour to solve the problems presented by wound treatment and disease prevention, and consequently the number of research centres that have arisen in France has little by little become quite large. In some instances their work has overlapped; in some, owing to ignorance of what others are doing, workers have gone over ground already explored; and in others rival projects for research have been put forward. It is to remedy these drawbacks that Sir Arthur Sloggett has created the new council, which will not, however, lessen the responsibilities or importance of the council whose institution by him early in the war we mentioned at the time. That body deals with any questions on which the D.G.M.S. British Armies in France, thinks it desirable to seek the considered opinion of a body consisting in equal numbers of men whose experience has been mainly civilian and of men whose experience has been mainly military. The new body will deal solely with the co-ordination and control of medical research. Its creation appears to us to be a further example of Sir Arthur Sloggett's happy capacity for seizing on the nodal point of any of the multiple problems that present themselves when a huge number of professional men are suddenly turned on to work which is familiar to them in many aspects but new to them in others. It is a capacity which in Sir Arthur Sloggett's case is combined with a talent of almost greater value—namely, that of making men see things from other peoples' points of view, and thus securing cohesion and loyal co-operation between hundreds of men all very differently trained, and all entitled in civil life in various parts of the world to consider themselves leaders and experts. The net result of the two capacities is that not only has the professional work in France been done on thoroughly scientific lines, greatly to the benefit of the British soldier and of the repute abroad of British medicine, but it has also been done by men who, for the most part, are satisfied with their lot, so far as any man can be satisfied so long as the persistence of war necessitates separation from his family and his private interests. These are among the reasons which enable us to look at the position of medical affairs in France with much satisfaction, whether we regard them from the point of view of parents and relatives of the British soldier, or from the point of view of the medical profession. They are also among the reasons why both parties would, we believe, not only regret any change in the directorship of medical affairs in that country, but very definitely resent it, unless brought about by absolutely unavoidable circumstances.

THE LIQUOR CONTROL BOARD.

THE fourth report of the Central Control Board (Liquor Traffic) deals with the year ending March, 1918. About nineteen-twentieths of the population of Great Britain live in areas covered by the Board's orders. The restrictions upon the output of liquor are imposed by the Food Controller, and during the year under review the amount of alcohol allowed to be sold was 50 per cent. less than in the previous year, but owing to the progressive dilution of spirits and the decline in beer gravities the bulk supply did not decrease proportionately, the reduction in the case of beer being under 30 per cent. In the areas affected by the Control Board's regulations the convictions for drunkenness have fallen to little more than a fourth of the figures for 1913; the reduction in the case of males was from 89,915 in 1913 to 20,801 in 1917, and among females from 28,352 to 9,415. It is thought that the convictions might have been fewer but for the fact that in some localities the supply of alcoholic beverages has been uneven, so that queues and what is called "rush" drinking, with their attendant evils, have tended to alternate with periods during which alcoholic beverages could not be obtained. The Control Board hopes that the methods that have now been put in force, with the co-operation of representatives of the licensed trade, will ensure a more even distribution. The decline in convictions was rapid down to the end of 1916 and continued during the earlier months of 1917 with no great diminution in rate; since then there has been a further improvement, which, though very slow and slight and not quite general, would appear to be still in progress. Contemporaneously there has been a notable fall in the number of deaths due to or connected with alcoholism; the number of deaths attributed to cirrhosis of the liver declined from 2,215 males and 1,665 females in 1913 to 358 males and 222 females in 1917. At the same time the deaths from alcoholic diseases other than cirrhosis fell from 1,112 males and 719 females to 358 males and 222 females. The number of cases of suffocation of infants by overlying, which have been shown to have some association with indulgence in alcohol, also declined, from 1,226 in 1913 to 704 in 1917. Cases of attempted suicide also show a notable decline, but, as was pointed out in a note on the Registrar-General's last report, published in our columns on May 4th, it is probable that the causes of this decline are complex, and that it cannot be attributed directly to decrease in drinking. The constructive part of the Board's work has made considerable progress. The number of industrial cauteens has risen from 570 in 1916-17 to 780 in 1917-18, the total number of persons catered for being nearly a million. The allowances from the earnings of controlled establishments which the Board has undertaken to recommend in respect of the provision of cauteens amount to over a million and a half sterling. Full financial details of the trading are not yet available, but it is estimated that after meeting all the usual trading charges—that is, after providing for rents, repairs, licence duty, rates and taxes, managerial and architectural staff, and depreciation on plant, furnishings, and utensils, the annual return on the capital commitments of the Board in its direct control undertakings has been at the rate of about 15 per cent. This, however, is a subsidiary matter, for the Board's primary object is not to make a pecuniary profit, but to control the liquor traffic as part of an effort towards the successful prosecution of the war. The reduction in drunkenness and its effects has been so considerable that there is now only a relatively small margin for further improvement. In conclusion the Board points out that whether the improvement that has been achieved shall prove permanent or temporary depends on unknown factors, particularly on future legislation and administration. The Board's experience, however, suggests that there is no such inherent difficulty in the problem as to render impossible the permanent maintenance of the present level of sobriety.

POST-GRADUATE TEACHING IN NEUROLOGY.

THE establishment of neurological hospitals throughout the country for the treatment of soldiers suffering from shell shock and war neuroses is an important step in reconstruction, for it is recognized that a large number of soldiers who are incapacitated by war neuroses can be cured by suitable treatment. The essential condition for treatment is correct diagnosis. The earlier the treatment of these functional neuroses, especially of the hysterical manifestations, is undertaken the easier is a cure effected. It has been calculated that the disorders of one-third of the whole of the unwounded soldiers discharged from the army belong to the group of functional neuroses. Hitherto men presenting hysterical contractures and paralyses of the most varied kind have been discharged and are receiving pensions, and unless something is done to prevent this a great and unnecessary waste of power and expenditure of public money will occur, for the longer these functional disabilities are permitted to remain the less curable they become. Dr. Addison, the Minister of Reconstruction, is fully alive to the importance of this matter, and recognizes that it is not only doctors serving in the army who are likely to have the care and treatment of these cases in the neurological hospitals, and who, in the interest of the state, require instruction in the methods of diagnosis and treatment, but also civilian medical men, especially panel doctors, among whose patients there will be for years to come large numbers of soldiers suffering with uncured neuroses or relapses brought on by emotional shock of a varied kind, even such as domestic and financial worries. The war indeed will leave for a considerable time a widespread emotivity in the population, which, unless care is taken, will be fostered by misplaced sympathy and reinforced by the idea of a pension for life. For this reason, Lieut.-Colonel Mott, after a consultation with Dr. Addison and the Director-General A.M.S., proposes to institute at the Maudsley Hospital a course of instruction to a limited number of civilian doctors and temporary R.A.M.C. officers interested in war neuroses and shell shock. The course will consist of lectures and practical instruction in the causation, diagnosis, prognosis, and treatment of functional diseases of the nervous system due to the war. Members joining the course will be afforded the opportunity of examining cases, writing reports thereon, and treating them under the direction of Lieut.-Colonel Mott or officers associated with him. Application to attend the course should be made to Brevet Lieut.-Colonel F. W. Mott, Maudsley Neurological Clearing Hospital, Denmark Hill, S.E.5. Fuller details will be decided later after a consultation with those wishing to attend the first course of instruction.

FACTORS IN RESISTANCE TO TUBERCULOSIS.

UNTIL recently the idea that resistance to infection need not entirely depend on specific immune bodies was largely ignored in experimental work, but certain investigators now believe that tuberculin has no special significance, and its beneficial effects no relation to active immunization, that the actual demonstration of an increase in antibody concentration in tuberculosis is not necessarily associated with favourable clinical results, and that recovery does not depend on the presence of specific antibodies. One of the factors influencing the resistance to tuberculosis, and bearing on treatment, is the ferment-antiferment content of the blood, and this new and rather intricate subject is considered in an interesting manner by Petersen.¹ The caseation in tuberculous formations is due to the inhibition of autolysis, which normally occurs in inflammatory products, by the unsaturated lipoids derived from the tubercle bacilli. These lipoids act as antiferments, and if they are removed or saturated with iodine the caseous material can be digested by trypsin. The

¹ W. F. Petersen, *Arch. Int. Med.*, Chicago, 1918, xxi, 14-38.

absorption of caseous material is thus prevented by anti-ferment action, but if the anti-ferments are diminished locally, or the ferments increased in the blood serum, autolysis occurs, and toxic bodies pass into the circulation. In pregnancy the lipoids of the blood and the anti-ferment content increase; the ferments also increase, but to a greater degree, and therefore begin slowly to digest the fibrous capsule of tuberculous foci, and so to liberate toxic bodies; but the patient feels well. At delivery the anti-ferments rapidly diminish, but the ferment content remains high, so that rapid digestion of the fibrous tissue around tuberculous material occurs, with liberation of toxic bodies and bacilli, thus favouring the spread of the disease. This corresponds with the clinical course of tuberculosis in connexion with pregnancy. In menstruation the proteolytic ferments of the blood increase, and in tuberculous women fever about the menstrual period may be explained as due to digestion of the fibrous capsule around caseous foci and passage of toxins into the blood. Thus, in pregnancy and the menstrual cycle, the activation of latent foci and the temperature changes do not bear any relation to antibody reactions. Tuberculin is not a native protein, but largely a mixture of polypeptides with a toxic action, and Petersen suggests that a subcutaneous injection of tuberculin damages some of the cells and thus raises the ferment content of the blood so that digestion of a tuberculous focus, if present, occurs and liberates some toxic bodies; in a non-tuberculous person nothing happens because there is no focus to be affected. Changes in the ferment-anti-ferment content of the blood may be produced by the injection of various vaccines and foreign proteins, and it therefore appears that the general reaction to tuberculin is not, strictly speaking, specific, though the cutaneous reaction is related to a definite sensitization. Any good done by tuberculin treatment is not due to an increase in antibodies but to a non-specific action—namely, alteration of the ferment-anti-ferment balance in the blood serum as in protein shock therapy. Although clinical experience shows that small doses of tuberculin are advisable, there is some evidence that occasional larger doses, with constitutional effects, may in certain instances be of greater benefit than the continued use of the minute doses commonly employed. It is interesting to note that the highly unsaturated fish oils, milk, cream, yolk of eggs, and phosphorus, empirically given in tuberculosis, increase the anti-ferment content of the blood, and so would inhibit proteolysis of the fibrous tissue surrounding tuberculous foci.

ANTIMENINGOCOCCIC SERUM IN CEREBRO-SPINAL FEVER.

In an epidemic of 208 cases at Camp Jackson, South Carolina, Dr. Herrick,¹ acting on the generally accepted view that at first cerebro-spinal fever is a septicaemia, has on logical grounds gradually evolved the treatment by large intravenous injections (200–600 c.c.m.), combined with free drainage and relatively small intrathecal injections of serum. The existence of the pre-meningitic stage of systemic infection lasting from a few hours to three days could be made out clinically in about half the cases. This modification of the treatment aims at the sterilization of the patient's blood before the meninges have become affected, and is thus an advance on the usual methods which have been concentrated on the later stage of meningitis, when, as Flexner insisted, subcutaneous and intravenous injection of serum have very little influence as compared with the intrathecal method. No bad effects were noticed from the large quantities of serum employed, indeed, a suspicion was aroused that small doses did some harm, and certainly the results were not so good as with large quantities. Mild cases of the disease do equally well with either intravenous or intrathecal injections of

serum; thus, of 36 cases by intrathecal injection one only proved fatal, but the intravenous injection of large quantities of serum reduced the mortality of the severe cases from 62 to 19 per cent. Among 16 cases of various degrees of severity treated by small intravenous (under 50 c.c.m.) and intrathecal injections the mortality was 43.2 per cent., whereas among 79 similar cases given large intravenous injections and average or smaller intrathecal injections the mortality fell to 16.4 per cent. Of the four clinical groups of cases—the abortive, the ordinary, the severe, and the fulminating—the most brilliant results were obtained in the severe cases; the patients often came rapidly out of coma with such remarkable recession of the symptoms that they were free from danger in two days, and anxious to be up on the fourth day. As a result of the treatment the patients have the cheerful optimistic air common in a convalescent surgical ward, subacute and chronic cases with cachexia, delirium, and other distressing symptoms are rare, the duration of the disease is shortened, the complications diminished, and the mortality lowered. In connexion with the free spinal drainage, which formed part of the treatment, attention should be directed to Cobb's method of obtaining a flow of cerebro-spinal fluid when lumbar puncture brings away a few drops only and the foramina may be obstructed. Under chloroform narcosis, which obviates muscular rigidity, the head is manipulated in order to break down adhesions about the foramen magnum and the floor of the fourth ventricle. This method, which might suggest danger from traction on the vagus roots, was often successful in starting a flow of cerebro-spinal fluid, and in one instance restored respiration after it had failed.

HORSE-FLESH AS HUMAN FOOD.

As every one's attention is now necessarily drawn to questions of food, and as criticisms on the rations naturally follow, perhaps raising the suspicion that the meat is the flesh of the horse, the issue of Dr. Leo Price's pamphlet¹ on the subject is appropriate. Horse-flesh was used as food by the early cave men in Northern Europe, and widely and extensively since in various parts of the world. Statistics for Great Britain are not available, but in 1910 Paris and its environs consumed twenty-nine million pounds of horse-flesh, and in 1909 over 150,000 horses and nearly 7,000 dogs were slaughtered in Germany for food. The prohibition by the Mosaic law, and by the papal decrees in the seventh and eighth centuries, together with sentimental feeling, is probably responsible for the prejudice against the use of horse-flesh as human food; but it is wholesome, nutritious, and economical. Deep red in colour, bordering almost on brown or black, horse-flesh shows a bluish sheen on exposure to the air, and when refrigerated turns black after fifteen days. One of its qualities is a slight sweet taste, but toughness is not a necessary characteristic any more than of any other meat. It contains a relatively large amount of glycogen; taurine is said to be present, and the fat is peculiar in its high content of olein and its very low melting point. When used exclusively, horse-meat may cause diarrhoea from the presence of a substance, soluble in alcohol, consisting of 75 per cent. lecithin and 25 per cent. neutral fat and cholesterol, and removed in the meat broth when the horse-flesh is cooked. By acting on this the diarrhoea can be avoided. It has been recommended that it should always be boiled or roasted. In comparison with the meat of cattle and pigs, horse-flesh is a negative factor in causing tuberculosis, and there are no parasites in horse-flesh accessible to man; but every precaution should be taken to eliminate glanders in horses offered for food, and it should be sold under special regulations so as to prevent substitution and adulteration.

MEDICAL INSURANCE AGENCY.

At a meeting of the Committee of the Medical Insurance Agency, on May 9th, Dr. G. E. Haslip, who was in the chair, referred with deep regret to the death of Mr. Guy Elliston, agent and secretary since the Committee was formed, to whose energy and good judgement so much of its success has been due. It was resolved to forward a letter of sympathy to his family. The chairman, in presenting the balance sheet for 1917, said that in spite of the fact that the country was now in the fourth year of the war the Agency had maintained its business all round and had been able to allocate the substantial sum of £1,000 to medical charities, the largest amount distributed in any one year since the Agency was founded. In addition the policy holders had benefited to the amount of £717, so that the total amount by which the profession had benefited through the Agency in 1917 was £1,717. There had been an increase in life and accident business, and even in respect of motor car policies the shrinkage in revenue had been exceedingly small. The Committee resolved to make an interim distribution for 1918 to medical charities of £500; it was allocated as follows: the Royal Medical Benevolent Fund, the War Emergency Fund, Royal Medical Benevolent Fund Guild, and the Belgian Doctors' and Pharmacists' Relief Fund, to each £100; Epsom College Benevolent Fund and Royal St. Anne's School for Girls, to each £50. As a result of this additional distribution the total sums allocated to medical charities by the Agency since its foundation have reached £3,905. It was resolved again to call the attention of the Royal Medical Benevolent Fund and Epsom College to the hope of the Committee that the two institutions should come to satisfactory arrangements with regard to settling any differences of opinion that might arise with regard to testamentary benefactions not clearly defined.

INFANT WELFARE IN GERMANY.

THE Local Government Board has issued a report¹ on infant welfare in Germany during the war, prepared by the Board's Intelligence Department. Information is given as to the birth and death rates, the special maternity grants which have been provided, and the other measures for saving the lives and improving the health of infants. The most striking fact is the heavy fall in the number of births. The first three years of the war reduced by over two million the number of babies who might have been born had peace prevailed. In 1916 the total number of births was 40 per cent. less than in 1913. In the months immediately following the outbreak of war there was a sudden rise in the infantile death-rate, but this has since been kept well down, at its worst it was never so high as in the very hot and dry months of 1911. The most noteworthy measures taken for infant welfare are the special grants to women who give birth to children. One of the grants is given only to those who breast-feed their babies. They are administered largely through the insurance societies, but the best opinion is in favour of administration through infant welfare centres, of which the numbers have increased since the war. Local authorities have been active in taking steps to overcome the difficulties of making proper provision of food for expectant and nursing mothers, and for infants and children. In contrast to this country, the infantile death-rate in Germany is higher in the rural districts than in the towns, and the improvements in infant welfare in Germany during the war have been effected principally in urban centres. Looking at the actual results of their well-advertised schemes and plans, we find the Germans still far behind our own country. Thus our infant death-rate is some 50 per cent. lower than that of Germany. The report is mainly based on information published in

German journals devoted to infant welfare, local government, medicine, and social reform; it will repay careful study.

THE Minister of Munitions has appointed a committee to advise him upon the general principles to be adopted in carrying out the welfare and health work of the Ministry, and to report on all matters connected therewith that may be referred to them. The committee is a mixed one, containing representatives of various interests, and the chairman is Mrs. H. J. Tennant. The medical members are Sir Walter M. Fletcher, K.B.E., M.D., F.R.S., secretary of the Medical Research Committee; Dr. E. L. Collis, Director of Welfare and Health Section, Ministry of Munitions; and Dr. T. M. Legge, medical inspector, Factory Department, Home Office.

Medical Notes in Parliament.

State Medical Service and the Proposed Ministry of Health.—

Mr. Booth asked Dr. Addison upon what ground the question of a state medical service was regarded as a forbidden subject in considering a Ministry of Health; and whether he was aware that many of the workers under the Insurance Acts were desirous of having the proposal thoroughly examined with a view to remedying some large and serious evils. Dr. Addison replied: The negotiations to which the hon. member refers were limited to the discussion of the redistribution of the functions of central departments in relation to health services. As stated in reply to a similar question on April 22nd, the question of a state medical service would not therefore have been relevant to the proceedings. In reply to a further question, Dr. Addison said that the negotiations with the various interests as to the Ministry of Health had been completed, and there was no disposition on the part of those concerned to suggest that personal claims entered into the important matters under consideration.

Royal Air Force Medical Committee.—Major Baird (Under Secretary to the Air Ministry) stated, in reply to Sir H. Greenwood on May 15th, that the Medical Administrative Committee of the Air Force had met on four occasions. The Director-General of the Naval Medical Service was present at three of the meetings. The Director-General of Army Medical Services was present at the first two meetings and sent representatives to the other meetings. In answer to Mr. Joynson-Hicks, Major Baird said that the Committee had arranged for the inspection of aerodromes. These inspections were being carried out by eleven senior medical officers of the navy and army, lent to the Royal Air Force. Reports had been received from them on nearly all aerodromes at which flying took place. All possible steps were being taken to meet the requirements for the medical service to the Air Force.

Retired Officers' Rights.—In reply to Major David Davies, on May 16th, Mr. Forster said that an officer of the Special Reserve placed on the retired list in consequence of wounds, but who had not relinquished his commission, was entitled to the gratuity awarded to officers who had left the service, and also to the issue of a Service Rendered Badge. They were permitted to wear uniform when employed in a military capacity, and on ceremonial occasions of a military nature.

Officers' Pensions Appeal Tribunal.—Sir A. Griffith-Boscawen, on May 16th, informed Sir M. Barlow that it was intended that officers invalided out of the Navy, Army, or Air Force, should have the right of appeal already possessed by non-commissioned officers and men as to whether their disabilities were or were not attributable to or aggravated by their naval or military service. A short time ago a special committee was constituted to act as the tribunal for dealing with officers' appeals.

Territorial Force Medical Officers' Gratuity.—Sir Watson Cheyne asked the Under Secretary of State for War, on May 13th, what was the reason why medical officers belonging to the Territorial Force could not be paid the gratuity which they had earned annually, as was the case with temporary medical officers, and was he aware that hardship often resulted from deferring this payment. Mr. Forster, in reply, said that the gratuity provided in the Pay Warrant for Territorial Force officers of all kinds was not payable until completion of service. In the case of the temporary medical officer the terms of the contract provided for the payment of an annual gratuity.

Malaria among Troops in Greece.—Mr. Macpherson, replying to Mr. Will Thorne on May 16th, said that the general health of the troops in Greece was good, but malaria was still prevalent. The admission rate for malaria, although high, was not due to serious cases. The death-rate fell from 5.64 per 1,000 in 1916 to 3.61 in 1917, and 2.51 for the first eighteen weeks in 1918.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN P. B. SEWELL, A.A.M.C.

Captain P. B. Sewell, Australian Army Medical Corps, was reported as killed in action, in the casualty list published on May 20th. He had previously been returned as missing.

Died of Wounds.

CAPTAIN R. MACGRATH, R.A.M.C.

Captain Roger MacGrath, R.A.M.C., was reported as having died of wounds, in the casualty list published on May 18th. He graduated M.B., B.Ch., and B.A.O. in the National University of Ireland in 1914, joined the R.A.M.C. as a temporary lieutenant on January 25th, 1915, and was promoted to captain on completion of a year's service.

CAPTAIN J. K. VENABLES, M.C., N.Z.M.C.

Captain Joseph Kendrick Venables, M.C., New Zealand Medical Corps, died of shell wounds in a casualty clearing station on May 9th. He was the son of the late Joseph Venables of Christchurch, New Zealand, and took the Scottish triple qualification in 1914. After acting as house-surgeon of the Christchurch Public Hospital, he joined the New Zealand Medical Corps. He received the Military Cross on January 1st, 1918.

Died on Service.

LIEUT.-COLONEL A. G. SARGENT, I.M.S.

Lieut.-Colonel Alfred George Sargent, I.M.S., died of angina pectoris in Mesopotamia on May 14th, aged 45. He was born on September 14th, 1872, the eldest surviving son of the late Lieut.-Colonel J. F. Sargent, I.M.S., and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1896. Entering the I.M.S. as lieutenant on January 28th, 1898, he became captain on January 28th, 1901, major on July 28th, 1909, and lieutenant-colonel on July 28th, 1917. He served in the third China war of 1900, receiving the medal. Before the war he held the appointment of superintendent of Rangoon Lunatic Asylum and lecturer on materia medica in the Rangoon Medical School.

Wounded.

Major E. J. Bradley, M.C., R.A.M.C. (S.R.).

Major E. E. Herga, M.C., R.A.M.C. (temporary).

Major K. N. Steele, Australian A.M.C.

Captain H. F. Brice-Smith, R.A.M.C. (temporary).

Captain C. Cairnie, R.A.M.C. (temporary).

Captain C. K. Carroll, M.C., R.A.M.C. (temporary).

Captain J. Colgan, R.A.M.C. (temporary).

Captain E. Forbes, M.C., R.A.M.C. (temporary).

Captain R. I. Forsyth, Australian A.M.C.

Captain L. V. Gatt, R.A.M.C. (temporary).

Captain E. D. F. Hayes, R.A.M.C. (temporary).

Captain M. P. Power, R.A.M.C. (temporary).

Captain E. C. W. Starling, M.C., R.A.M.C. (S.R.).

Captain E. G. Thomson, Australian A.M.C.

Captain R. P. Wheeler, M.C., Australian A.M.C.

Lieutenant A. C. Reid, R.A.M.C. (temporary).

Lieutenant J. A. Stewart, R.A.M.C. (temporary).

Missing.

Captain A. B. Cluckie, R.A.M.C. (temporary).

Prisoners of War.

Major J. Kennedy, R.A.M.C. (S.R.).

Captain W. Arnott, R.A.M.C. (temporary).

Captain S. A. Forbes, R.A.M.C. (temporary).

Captain C. G. Gibson, R.A.M.C. (temporary).

Captain W. H. McCarter, R.A.M.C. (temporary).

Captain H. C. Martin, R.A.M.C. (temporary).

Captain E. E. Mather, R.A.M.C. (temporary).

Captain C. A. Meaden, R.A.M.C. (temporary).

Captain C. Mearns, R.A.M.C. (T.F.).

Captain R. M. Soames, R.A.M.C. (temporary).

Captain D. F. Troens, R.A.M.C. (temporary).

Captain E. Underhill, R.A.M.C. (temporary).

Lieutenant J. A. Loughridge, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Davies, Geraint, Captain, elder son of Dr. Morgan Davies of London, student of Guy's Hospital, died of wounds, April 14th, aged 22.

Davis, Guy Clifton, Lieutenant Northumberland Fusiliers, youngest son of the late Dr. Robert Davis of Orpington, Kent, died at a casualty clearing station on May 11th of wounds received on April 19th, aged 23. He got his commission on February 4th, 1915.

Harrhy, Ramsay, Corporal, late Captain, Bechuanaland Fusiliers, son of the late Dr. Harrhy, J.P., of Barkly West, South Africa, died of wounds, May 10th, aged 28.

Mason, Ethelbert, only son of Dr. J. R. Mason of Newcastle-upon-Tyne, died in France, May 12th. He was an undergraduate of the Durham University.

Sumner, Geoffrey, Lieutenant, son of Dr. Sumner of Waterloo, Liverpool, died on May 11th in his 22nd year. After joining the forces as a private in the Royal Field Artillery he obtained a commission in the Royal Air Service, but was subsequently invalided home on account of ill health.

Thompson, G. P. N., Lieutenant Royal Dublin Fusiliers, only son of Dr. C. J. Thompson of Newport, Isle of Wight, killed May 4th, aged 19. He was educated at Epsom College, got his commission through Sandhurst in July, 1916, became lieutenant in January, 1917, and went to the front in September.

Weir, T. H., Major Royal Engineers, second surviving son of Dr. J. Johnstone Weir of Jarrow-on-Tyne, killed May 8th. He became lieutenant in the Third Durham (Gateshead) Field Company of R.E. on May 11th, 1915, and got the command of a company last October. He had twice been mentioned in dispatches.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

THE following special promotions are announced in recognition of the services of the officers mentioned in connexion with the recent attack on Zeebrugge: *To be Fleet Surgeon:* Staff Surgeon James McCutcheon, R.N. *To be Staff Surgeon:* Surgeon Henry St. C. Colson, R.N. Temporary Surgeon F. P. Pocock, M.C., R.N., is noted for early promotion. A statement of the individual services rendered by the officers promoted will be issued as an appendix to Vice-Admiral Keyes's dispatch.

MENTIONED IN DISPATCHES.

The first list of names brought to notice by Sir Douglas Haig in a dispatch dated April 7th, 1918, for distinguished and gallant services and devotion to duty between September 25th, 1917, and February 25th, 1918, includes temporary Surgeon W. J. McCracken, D.S.O., M.C., attached R.N.V.R., and Major and brevet Lieut.-Colonel E. Ryan, D.S.O., R.A.M.C. The list of officers of the medical service mentioned in the dispatch will be published in a Supplement to the *London Gazette* at a later date.

Surgeon Maitland Bodley Scott, R.N., is among the officers mentioned in dispatches (*London Gazette*, May 17th).

COMMENDED FOR SERVICES.

The following are among the officers brought to notice by Lieut.-General Sir A. A. Barrett for valuable services rendered during the operations against the Mahsuds (March to August, 1917): Colonel P. Hehir, C.B., C.M.G. Lieut.-Colonels L. Addams-Williams, R.A.M.C., P. H. Faulkner, R.A.M.C., G. G. Giffard, C.S.I., I.M.S., C. H. S. Meyer, I.M.S., F. R. Ozzard, I.M.S., J. B. Smith, I.M.S. Majors C. C. Morrison, I.M.S., G. E. Stewart, I.M.S. Captains J. A. Sinton, V.C., I.M.S., J. M. Weddell, R.A.M.C. 1st Class Assistant Surgeons H. A. Poyntz and W. H. Thiphrop, I.S.M.D.; and Dr. R. Cox of the Church Missionary Society.

NOTES.

CONFERENCE ON CARE OF DISABLED MEN.

THE work of the Inter-Allied Conference on the after-care of discharged sailors and soldiers has proceeded at the Central Hall, Westminster, this week, in accordance with the programme published in this column last week. The conference, which is attended by representatives of the United States, France, Italy, Belgium, Canada, Portugal, and Serbia, and by about one hundred British representatives, including those from Australia, New Zealand, South Africa, and India, was opened by the Duke of Connaught on Monday, when Mr. Hodge, the Minister of Pensions, was in the chair. The Duke's speech of welcome was acknowledged by Dr. Bourrillon for France, Professor Enrico Burci for Italy, and Lieut.-General Melis for Belgium. Apart from the work done in the sections a great deal of interest has been excited in the exhibition, which was visited by the King and Queen on Monday. It consists partly of soldiers' work in various trades, and partly of artificial limbs and appliances, also, in many cases, made by

disabled men. Italy, whose representatives have taken a large part in the work of the sections, makes a very effective display in the exhibition. The French exhibition is largely concerned with the work of the re-education schools at Paris, Havre, Lyons, and Marseilles. The British display is mainly from the various military orthopaedic centres in this country. The Canadian and Australian sections are also very interesting, and much of the work done is for their hospitals in this country. The Scottish Hospital for Limbless Sailors and Soldiers at Erskine is represented, and it was shown that the pattern shops of the Clyde have co-operated in making artificial limbs on a standardized plan. The Serbian Red Cross has a most interesting exhibition, chiefly of artistic work made from war débris.

During the week delegates have paid visits to various institutions for disabled men in the neighbourhood of London, and on Tuesday, May 21st, they were entertained at dinner to the number of between one and two hundred by the Lord Mayor of London.

SCOTTISH WOMEN'S HOSPITAL WITH THE SERBIAN ARMY.

The Elsie Inglis Unit of the Scottish Women's Hospitals, which left London at the end of February, after inspection by the King and Queen, reached its destination on the Macedonian front on April 1st, and the camp was ready for the reception of patients a fortnight later. The Jugo-Slav division of the Serbian army, to which the unit is attached as sole field hospital, has been in severe fighting since then, and the wards are now filled with sick and wounded brought straight from the front. The hospital has its own transport, and the girl drivers make daily rounds with the motor ambulances to fetch in the cases.

England and Wales.

LONDON WATER.

In his twelfth annual report Dr. A. C. Houston, Director of Water Examination, Metropolitan Water Board, records the results of the chemical and bacteriological examination of the London waters for the twelve months ended March 31st, 1918. From March, 1915, onwards "resistance to filtration" experiments, which had been made from time to time for twelve years, were systematized and a bi-weekly check kept on the quality of all the prefiltration waters, twenty to twenty-four in number. The results are of considerable practical as well as scientific importance, as upon them, it is said, depends the possibility of anticipating filtration difficulties by inhibitory algicidal treatment. Though algal growths can be destroyed, yet the risk may remain of other and more resistant growths taking their place. A notable instance occurred in 1917 during the continuous treatment of No. 1 reservoir at the West Middlesex works with copper sulphate (1 in 4 millions). While the growths (*Fragillaria*, *Asterionella*, *Stephanodiscus*, filamentous confervoid growths, etc.) affecting the neighbouring reservoirs were almost completely held in check, a fresh growth, composed of cells so excessively minute that they readily passed through four folds of fine linen, developed abundantly, and caused serious blocking of the filters. In his twelfth research report Dr. Houston dealt in detail with the successful results of the chlorination of raw river water, and showed that a better water could be provided, with a saving of coal and cost generally.¹

Last year it was reported that experiments with liquid chlorine had been started, with gratifying results. This year, he says, a much more cautious opinion must be expressed, not of the efficacy of chlorine as a germicidal agent, but of the difficulties that have to be overcome in adding this reagent to water in the proper dose. With the apparatus used successful results were obtained during the warm weather, but when the air and water temperature fell below a certain point there was trouble. Practical experience during cold weather shows that either the gas must be added as a solution to the water to be sterilized or some improved form of porous diffuser must be discovered. Taking a period embracing the bad winter months, from October, 1917, to the end of March, 1918, the average chlorinated raw river water results work out at 83 per cent. "negatives" and 17 per cent. "positives," figures which show that, as judged by the *B. coli* test, better

results can be obtained by chlorination than by storage. Despite the magnitude of treatment (70 to 80 million gallons daily) no complaints as to taste were received. Storage, however, has an important "levelling" or "equalizing" effect. A clear saving of nearly £12,000 a year has been effected by substituting chlorinated for stored river water, but Dr. Houston does not attempt to plead that the former gave not only equal but additional security to the consumer. If, however, chlorinating the water were to lead to the blocking of the sand filters, this might be urged as an objection to the method. Dr. Houston considers that, though it may be presumed that after the war the cost of pumping will fall in far greater ratio than that of chlorination, the margin will always be in favour of chlorination. The two great factors which militate against successful chlorination are extreme cold and short contact. Separately, and still more in conjunction, they tend to prevent sterilization, or if sterilization takes place owing to a superdose—that is, a dose in excess of what is actually required under more favourable working conditions—the water is apt to have a chlorinous taste and to contain active chlorine. Dr. Houston sets forth the results of his experiments in a number of clearly arranged tables.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

The annual meeting of the Governors and General Council of King Edward's Hospital Fund for London, to receive the accounts and the report of the General Council for the year 1917, was held at St. James's Palace on May 14th, the Speaker of the House of Commons being in the chair. Lord Revelstoke (the hon. treasurer) was able to report that the Fund had again made a substantial increase in the distribution, and had also added to its reserves. If the ordinary income showed no decrease the Fund should be able to maintain the distribution at or near the total arrived at in 1917. Mr. Frederick M. Fry (hon. secretary) presented the draft report of the Council for the year 1917. The grants amounted to £190,000, being £20,000 more than in 1916. The expenses of administration were £1 9s. 0½d. per £100 of the total amount received, in spite of the increased cost of printing and paper. Sir Henry Burdett drew attention to the importance of keeping up and increasing the amount received from subscriptions and annual donations, and Lord Somerleyton undertook to bring the matter before the Executive Committee.

CENTRAL MIDWIVES BOARD.

At a meeting of the Central Midwives Board on May 16th, Sir Francis Champneys presiding, the re-election for one year of Mr. Sangster as a member of the Board was announced. It was decided to call the attention of the Local Government Board to a form issued by a local supervising authority, and particularly to the note at the foot, which seemed to the Board to be an endeavour to enforce the notification of pregnancy on midwives, and to ask the Local Government Board to deal with the matter. It was decided to bring the action of a medical practitioner in giving a certificate to an uncertified woman stating that she was "quite capable of undertaking the duties of an ordinary midwife," to the notice of the General Medical Council, and to express the Board's willingness to appear as prosecutor, if desired, should the Council take action in the matter. Seven women were removed from the roll on their own applications. It was decided to increase the price of the Midwives Roll to one guinea, and to ask the Treasury to contribute £117 3s., the estimated cost of 375 copies of the roll additional to those required for sale to the public.

Scotland.

The work of the Glasgow Day Nursery Association is about to be transferred to the Corporation of Glasgow. The association has been at work for thirty-five years and its nurseries are well equipped, but the funds at its disposal are too limited to allow the full development of a child-welfare scheme by it.

NEURASTHENIC SOLDIERS.

At a meeting of the Scottish Joint Institutional Committee, over which Sir A. Griffith-Boscawen, M.P., presided last week, it was reported that the extension of Craigend

¹ BRITISH MEDICAL JOURNAL, July 21st, 1917, p. 97.

neurasthenic home was proceeding satisfactorily and would provide beds for fifty or sixty patients. The orthopaedic annexe at Tynecastle would shortly be ready. The Chairman pointed out that under the new pensions warrant allowances would be paid to the families of men undergoing treatment for disabilities not attributable to service. Dr. Fletcher Porter stated on behalf of the Ministry of Pensions that, owing to new arrangements made by the Army Council, these cases would in future be treated in special hospitals before discharge. It seemed probable, therefore, that no soldier would be discharged who required institutional treatment for any functional nerve disorder. A scheme for making additions to the Springfield farm colony for tuberculosis is under consideration.

Ireland.

We are informed that Captain J. C. McWalter, M.D., R.A.M.C., has been invited to become a candidate to represent the National University of Ireland in Parliament, and has given a provisional consent. It is, we are informed, expected that a candidate in the Sinn Féin interest may also contest the seat. Captain McWalter, who has been a member of the senate of the university since 1914, is an alderman of the city of Dublin, and was chairman of the Dublin Insurance Committee until he joined the R.A.M.C.

THE CONTROL OF SYPHILIS.

At a meeting of the Section of State Medicine of the Royal Academy of Medicine of Ireland, on April 12th, with the President, Sir William Thompson, in the chair, Dr. Kirkpatrick read a paper on the state and syphilis. He outlined the action of the state in England in its control of prostitution since the time of Henry II, and referred to the regulations enforced in Scotland at the end of the fifteenth century for the prevention of the spread of syphilis. In England an Act was passed in the middle of the eighteenth century regulating the method of prosecuting those who kept bawdy houses. Dr. Kirkpatrick discussed the recent legislation that has followed the publication of the report of the Royal Commission on venereal diseases, and the schemes at present under the consideration of some of the Irish sanitary authorities. He urged the cordial co-operation of all medical men in the carrying out of such schemes. Sir John Moore drew attention to the fact that in the Venereal Diseases Act, 1917, medical treatment by unqualified persons was for the first time in England made illegal. Professor McWeeney said that some Dublin hospitals would not undertake the treatment of patients suffering from these diseases in an infectious stage, while the authorities of some of the university and college laboratories objected to such patients attending the laboratories for the purpose of diagnosis. Dr. Crofton said that as it was almost impossible to say when patients with venereal diseases were cured, more was to be hoped for by prevention than cure. He advocated strongly the use of prophylactic applications to prevent infection. Sir Andrew Horne referred to the advantages and limitations of the Dublin Lock Hospital. He believed that syphilis in Dublin was increasing, and urged the importance of establishing places where patients suffering from it could be adequately treated. Dr. Coey Bigger gave an account of the action taken by the Local Government Board for Ireland. He hoped that shortly there would be several schemes for treatment started in Ireland. Dr. Joseph Bigger described the work that had been done in Sheffield under the scheme in force there. He pointed out the great difficulty in making a diagnosis of gonorrhoea in the laboratory. The President referred with satisfaction to the change in public opinion with regard to the treatment of patients suffering from these diseases, and from this change he expected and hoped that a great improvement in public health would result.

THE Town Council of Madrid has decided to establish a school of "Maternology" to be under the direction of the professors of the municipal institute of puericulture. Practical courses of instruction will be given at various centres in the capital.

Correspondence.

A MINISTRY OF HEALTH.

The British Medical Association Scheme.

SIR,—I have read the pamphlet, *A Ministry of Health*, issued by the British Medical Association, with interest, but to me the whole scheme is humdrum and unimaginative: there is no insight or ideal. It contains no bold device for the betterment of the people, or the improvement of the lot of the general practitioner, and little for the advancement of medicine. It may be said to be only the glorification of the national insurance.

No reference is made to the doctrine that it is the duty of the doctor to cure the patient in the least possible time, so as to return him to work as soon as may be, and the duty of the patient to do all he can to promote his own recovery, although the whole scheme is good or bad according to the degree in which it enables this to be effected. I make bold to maintain that the doctor cannot give efficient attention to every case so long as he knows that he has to work at high pressure to earn enough to keep the home together—it is not fair to either the doctor or the patient. It follows that more doctors are urgently needed, even in times of peace, and to get them it is essential that the conditions of work should be improved, including the pay. It is suggested that practitioners should be encouraged to specialize; they have not the time at present, yet the mass of clinical material they see would be most valuable if it were only collected. The continuance of the voluntary hospitals, with their debts to hamper their work and their long waiting lists, is advocated on the ground that they compare favourably with the hospitals of certain Continental countries, whereas it is just as reasonable to say the difference is due to national characteristics and traditions. There must be far more hospitals, and to try to combine voluntary and state ones would be fatal.

A state service would involve all branches of medicine being under the state—hospitals, schools, qualifications, research, etc. The state would obtain drugs and appliances at a much more economical rate than is now paid under insurance. To the members of the profession it would mean better conditions generally—if not, the whole thing would be a failure as great as the present state of things—better pay, better conditions under which to work, better opportunities for improving one's knowledge, better chances of rest (for example, holidays), better chance of retiring owing to the pension; to the public it would mean better treatment and an earlier return to work; to the state it would mean increased powers of production. I have not referred to the nurses, dentists, and dispensers, but they would have to be incorporated in the state service.

I doubt whether there is a calling, except the Church, which can claim such unselfish work as the medical profession. Our aim is the betterment of the lot of humanity, our thanks are often kicks. If we are to be in a condition to realize our aims, it is essential that we should have our own condition improved. "The greatest good for the greatest number" is really our ideal, and it is from that standpoint that we must build any suggestions we have to offer, and remember that for each of us there are roughly two thousand other persons in these islands.

I do not suppose that any one who is interested in the health of the nation wishes to "raise false hopes" or anticipates a "sanitary millennium" any more than a moral millennium; what is wanted is a scheme which will permit of the grafting on to it of each improvement with the least possible disturbance. The British Medical Association scheme does not appear to do so.

Maternity hospitals are suggested, but not the suppression of the midwife. We appear to have forgotten the outcry about giving the mother in labour over to an inferior class of practitioner, yet it is still true that no labour is free from danger till an appreciable time after it is completed.

The choice of doctor is really a very beautiful idea, worthy of the poet's song; but is it practical to-day? So long as every individual can afford to pay a doctor privately no interference is needed, but as soon as some people need assistance to obtain treatment there is no logical reason why others should not claim it. Why

should X. have to pay for Z.'s medical treatment and not be able to obtain assistance when he is ill himself? The lack of means has cost many an one his or her life; what has it cost the country? Every individual has a right to be supplied with medical treatment by the state, and the state has a right and a duty to supply it if it considers the best is not obtained. A conservative British nature will grumble at first at the loss of choice and then willingly acquiesce, later on to praise the arrangement, if only because it was thought to be British.

There would always be a certain number of people who could afford to engage a private doctor and pay good fees, so that those who did not want to remain in the service could try their luck outside, but the existence of a public service would be a sufficient excuse for keeping fees at a high level.

The whole change would probably require considerable time to effect, but so long as a definite plan existed it could be carried out systematically; but, in any case, one upheaval is better than repeated tinkering with an unsatisfactory condition of things.—I am, etc.,

Mumbles, May 18th.

F. DE COVERLY VEALE.

EXTRA RATIONS FOR TUBERCULOSIS PATIENTS.

SIR,—The fact that the profession are asked to fill up the required forms specifying the amounts of meat and butter to which patients are entitled suggests that we should discriminate between those likely to benefit from the extra ration and others who are too ill to require it. It is possibly eaten by other members of the family who are not entitled to benefit.

A patient to whom it was refused raised an objection, and I therefore wrote to the Ministry of Food for instructions, and in reply was informed "All cases of active tuberculosis are eligible for extra rations of meat and butter but not sugar, and should be notified." Of course all cases are notified, but this reply suggests that the profession might be saved much time and difficulty in decision if the local food office were confidentially supplied with a list of notified cases, and themselves issued the necessary forms, for in many cases it takes a brave man to say that the disease is no longer active and does not require extra feeding to prevent recrudescence.—I am, etc.,

Halstead, Essex, May 15th.

C. GORDON ROBERTS.

ACUTE GONORRHOEA TREATED WITH VACCINES.

SIR,—In his article on vaccine treatment in acute gonorrhoea (BRITISH MEDICAL JOURNAL, 1917, vol. ii, p. 450) Captain N. P. L. Lumb, R.A.M.C., arrives at a series of conclusions which appear to be quite unwarranted. His thesis is that vaccines are of considerable value in the treatment of acute gonorrhoea. His method is to give two courses of vaccine treatment, each course consisting of six doses extending over fifteen days, the two courses occupying forty days, allowing for an interval. Now before the results can be of the slightest value in a comparative sense, no treatment other than vaccine treatment must be employed at the same time. But in Captain Lumb's series of cases, in addition to and contemporaneously with the administration of vaccines, the patients were having irrigation by Janet's method twice daily. It must be clear to Captain Lumb that before his results can pretend to be of any value he must have other methods of treatment with which to compare them. For instance, if out of 300 cases he had treated 100 with vaccines alone, 100 with Janet's lavage alone, and 100 by the two methods combined, then there might have been some value in his publication.

His results in five hundred cases in no manner justify his contention that vaccines are of any great value in acute gonococcal urethritis. They are in no way striking, and the value of the treatment seems to be rather, as judged from the results, below the ordinary.

When the Janet method of *grand lavage* alone is properly carried out, much better results are obtained and the proportion of complications is less than in Captain Lumb's series of cases. The explanation of the occurrence of 26 per cent. of complications—epididymitis, prostatitis, etc.—is obviously that "the patient is instructed to

thoroughly wash out the anterior urethra first and then to get the solution into the bladder." It shows a high degree of optimism to expect that the patient will be able to carry out these instructions. Experience has shown that it is only in rare instances that such will be done. The usual result of allowing the patient to carry out the irrigation himself is to ensure the conversion of an anterior infection into a posterior one with the complications of epididymitis, prostatitis, and cystitis.

Regarding the general effects upon the patient all of them—mental relief at the rapid disappearance of the discharge, rapid disappearance of pain, and that exercise can be taken without delaying the cure—can be attained as rapidly, if not more so, by the method of lavage alone. Were the treatment carried out by injection of vaccines alone there would be some justification for the assertion made by Captain Lumb that his method has a beneficial effect upon the mental state of the patient in that "anything which tends to turn his thoughts away from the site of the disease and associated ideas is valuable." But as the treatment partially consists of Janet irrigations twice daily, which must direct the patient's attention to the site of the disease, the statement just quoted seems to be devoid of point.

Captain Lumb's article is apt to lead others to imagine that there is some clear value in vaccine treatment, a thing which has only been asserted but not proved in his publication. The danger of Captain Lumb's statement is that others may act upon it, and waste time by treating cases of acute gonorrhoea by vaccines alone, or combined with a modified course of irrigations not thoroughly carried out.—I am, etc.,

Mesopotamia, March 16th.

E. T. BURKE.

QUININE IN MALARIA.

SIR,—After over twenty-five years' experience of malaria in far apart tropical and subtropical countries, I still maintain that quinine is a good prophylactic and a good drug in the treatment of this disease. My cases got well or improved, after I learnt from experience how and when to administer quinine.

It was, and for all I know is still, the custom in tropical countries for newcomers to be told by doctor and layman, "You must take a good pinch of quinine every day—10 gr. or so—in tabloid or wrapped up in a cigarette paper." The newcomer generally does so, and as a rule gradually develops indigestion, with vomiting, suffers from inanition, becomes cachectic, and gets malaria *plus* quinine poisoning. The doctor is sent for, and as a rule prescribes a large dose of solid quinine. The patient becomes worse, and the quinine is blamed.

A good many years ago on the West Coast of Africa I was dosed with quinine as a prophylactic, as described. I did not contract malaria, but I developed indigestion and gastritis due to the irritant effect of the solid quinine, little, if any, of which was dissolved by the gastric juice at first, and none at all later on.

Years later I contracted malaria in Marysville, California, and was nearly poisoned by a well-meaning physician, who dosed me with solid quinine. Later I held an official appointment in Rhodesia, where malaria of a severe type was rampant in the outlying camps. I treated it in the way I had been taught, and allowed the officers and men to follow the instructions issued by those in authority, namely, to dose themselves daily with quinine powders or tablets. I myself got a severe attack of malaria contracted at a pestilential camp, and then learnt useful facts about quinine, which, although probably known to many, are worth setting forth, namely:

1. To administer calomel always before giving quinine, unless calomel is contraindicated by some other disability of the patient.
2. Never to give quinine in solid form by the mouth or rectum, but always in solution (in dilute sulphuric acid by preference).
3. Never to give quinine during a high rise of temperature, but to wait until it has subsided in the ordinary way, or been reduced by sponging, etc.
4. Never to give quinine on an empty stomach, and in many cases to give alcohol in a moderate quantity almost immediately after the quinine, or champagne in exceptional cases.

5. To build up the strength of the patient by every means available during the periods of intermission.

6. Never to neglect the idiosyncrasies of each patient, his response to small or large doses, and the general effect of the drug upon him.

7. To discourage the indiscriminate and unscientific method of "shovelling" large quantities of solid quinine into each and every stomach irrespective of the constitution, temperament, and chemical reaction of the individuals concerned.

I found that the administration of quinine given without attention to these rules was the cause of much illness amongst officers and men, that their constitutions and resistance became weakened, and when they developed malaria generally suffered severely.

From experiments upon myself and others I found quinine a good prophylactic given as follows: On the first of the month, say, a dose of calomel to suit the individual was administered, and, after the bowels were well cleared, 15 grains of quinine dissolved in dilute sulphuric acid was given, after a good meal. On the 15th of the month another dose of calomel and another dose of quinine (15 grains) was given, and the individual was advised to pay strict attention to the bowels at all times.

After adopting this plan malaria became less frequent and severe in camp and out-stations, and was more easily treated.

In the treatment of malaria I found quinine satisfactory when given with due regard to the points above enumerated.

I met the late Professor Koch when he was in Bulawayo. He told me he had always adopted the rules I mentioned, and that neither he nor his assistants suffered from malaria during their long residences in malarial districts.—I am, etc.,

London, W., May 21st.

EDWARD YEATES, F.R.C.S.I.

"BOTULISM" AND MENINGITIS.

SIR,—Would your readers care to learn from one who has been over-persuaded by the recent Local Government Board memorandum on "an obscure disease with cerebral symptoms"?

My case was in the Evelina Hospital—a child of 6 years, who became drowsier and drowsier until she would, for example, fall asleep over her meals in bed; but she was never comatose and could be roused easily enough. She developed bilateral ptosis, dilated pupils, pyrexia, constipation, and retention of urine. She had no other paralysis, no rigidity, no fits, no optic neuritis, and no Cheyne-Stokes breathing. Lumbar puncture brought no fluid, though we tried half a dozen times.

Fortified by what we had read we all thought she must be our first case of botulism—until she died and Mr. Leatham demonstrated tubercles in the pia arachnoid.—I am, etc.,

London, W., May 20th.

DAVID FORSYTH.

UNIVERSITY REPRESENTATION IN PARLIAMENT.

SIR,—In reply to Dr. Kingdon, I would point out that the reason no invitation to our meeting was sent to him was that in the London section of the *Medical Directory* his address is given as c/o British Medical Association, 429, Strand, W.C.2 (on military service). From this I assumed that he was overseas, and therefore would not be able to attend.

I am sorry he should be aggrieved, but we did take great pains to find names and addresses of graduates, a somewhat difficult matter.—I am, etc.,

HERBERT G. WILLIAMS,

Hon. Sec., Combined Universities Conservative and Unionist Association.

London, S.W., May 18th.

WHAT IS A CONSULTANT?

SIR,—As a general practitioner, in a rural district with no druggist, I sent a patient with my letter to a specialist, who saw the patient, wrote to me, gave a prescription, and took his fee as a specialist, and the prescription is brought to me to be dispensed. This has been done now for many months; during this time the patient has gone up to town and seen the consultant occasionally, and for all this time I have not been called in once to that patient. It seems to me that my patient was seen once as a specialist and

ever after as a general practitioner. If this is so, I must in future refuse to give my good patients away and to become (because we have no druggist) the specialist's dispenser.—I am, etc.,

May 18th.

GENERAL PRACTITIONER.

REMOVAL OF WORM (FILARIA LOA) FROM THE EYE.

SIR,—In my paper which appeared in your issue of May 4th, 1918, I stated that the worm was a female. The specimen was examined for me by a tropical expert, and the statement was made on the strength of his evidence. Dr. Leiper has since kindly examined the worm, and has conclusively demonstrated to me that it was a male. I greatly regret the error, and shall be obliged if you will allow me to put the matter right as soon as possible.—I am, etc.,

London, W., May 21st.

R. H. ELLIOT.

The Services.

PAY AND GRATUITY OF TERRITORIAL OFFICERS.

WE would refer a correspondent who asks a question on this subject to Section VI of the Royal Pay Warrant of the Army, which deals *inter alia* with the emoluments of officers of the Special Reserve of Officers and Territorial Force employed on army service.

Article 496 (b) lays down that officers specially taken into employment by reason of a national emergency shall receive while so employed the same rates of pay and allowances as officers of corresponding army rank in the same arm or branch of the service; or if holding a command, or employed on the staff, the rates of consolidated pay laid down for their appointments. Such officers may include those of the Special Reserve of Officers and Territorial Force employed with the Regular Army.

Article 497 lays down that officers employed under the above conditions shall, provided that they serve for the full period of their engagement, or of the emergency in respect of which they are employed (unless a shorter period is specially approved by the Army Council), be entitled on the cessation of such employment to a gratuity at the following rate: 124 days' pay for the first year of service, or any part of a year, and sixty-two days' pay for each subsequent year of service, or part of a year. For the purpose of such gratuity pay is held to mean regimental, departmental, or staff pay only, and not to include additional pay of any kind, or (except in the case of officers drawing consolidated rates) allowances.

Reference may also be made to Mr. Forster's reply to Sir Watson Cheyne in the House of Commons, reported on page 599.

PROMOTION OF NAVAL SURGEONS.

AN Order in Council, published on May 17th, authorizes the Lords Commissioners of the Admiralty during the period of hostilities and for twelve months thereafter to dispense with the prescribed examination to qualify for promotion to the rank of staff surgeon, R.N., and to promote to the rank of staff surgeon all surgeons qualified by length of service, with retrospective effect accordingly where necessary, who have had uniformly good reports during their naval service, and who are recommended for such promotion by the Director-General of the Medical Department, R.N.

AIDES-DE-CAMP FOR MEDICAL GENERAL OFFICERS.

SURGEON-GENERAL G. J. H. EVATT, C.B., A.M.S., ret. (London, W.), writes: Wherever a medical "general officer" is employed either in direction of the medical affairs of a "command" in England or of an "army corps" or "army" in the field, he should "by order" have an aide-de-camp on his personal staff.

2. This officer should be a medical officer not above captain's rank, and should have gone through four months' staff training in the head quarters offices of a "command" at home or abroad.

3. An aide-de-camp attends to the housing, the feeding, and the transportation of his chief, and so greatly helps that officer's fitness in the field. I have seen pitiful results from the absence of such an officer on a directing medical officer's staff. Further, the aide-de-camp acts as "gentleman usher" to his chief, and prevents his being intruded on by every casual inquiring visitor. He is able to see visitors, and himself give them much of the information they desire. He also can be sent on messages to distant officers, to convey important orders—or to make inquiries of a confidential character. A young man himself, he hears the gossip of the camp, often very valuable to know, and he learns either of neglects or failures which would never come direct to a medical general officer's ears. For want of such an officer, directing medical officers of considerable age and seniority have broken down in the field, or come back as wrecks after directing the medical affairs of a stiff campaign.

I strongly advise the recognition of such an officer, and compulsory orders should exist directing general medical officers to nominate such a personal staff officer. I am positive that a

medical officer employed in this capacity during a campaign, so far from being injured in his medical or sanitary efficiency by this duty, would, at the end of his term of service, be a far more valuable medical officer than he could have been without this experience. Whatever he may cost the state he will amply repay that expenditure in the bettered efficiency that may result to the medical service in the field. We failed in our old wars largely for want of a trained directing staff, and the absence of an aide-de-camp has helped on failure, and has at times broken down completely the health and efficiency of medical directing officers.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE Senate has elected Dr. F. Gowland Hopkins, F.R.S., Professor of Biochemistry, as the Representative of the University on the General Medical Council for a term of five years, in succession to Professor Sir Clifford Allbutt, who did not offer himself for re-election.

At a congregation held on May 18th the degree of M.D. was conferred on W. C. D. Maile.

UNIVERSITY OF EDINBURGH.

Finance.

THE General Council of the University, on May 16th, approved an ordinance containing regulations for the administration of the finances of the university. The ordinance in force dates from 1895, and requires that a number of funds should be administered separately and independently. Experience has shown that this is inimical to the free development of the university. Another defect was that the salaries of the professors fluctuated according to the state of the fee fund at the moment; many of the salaries were too low, not exceeding £600 in a number of instances. The new ordinance would bring all the funds into a general revenue and expenditure account, and under it a professor's salary would never fall below £700. The Principal said that the purpose was not so much to alter professors' salaries as to simplify the university accounts. He added that Edinburgh had suffered more than any other of the universities, except possibly Oxford and Cambridge; in three years of war its loss in fees amounted to £52,000, and the net result was to leave it £27,000 the bad. Though the position had been relieved by a special Treasury grant of £14,500, it still caused anxiety.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following were, on May 16th, admitted Fellows: J. J. Armistead, W. T. Garretson, S. Green, E. W. Lewis, V. D. Nimbkar, E. H. Roberts, A. L. Yates.

The Bathgate Memorial Prize has been awarded to Miss Janet A. A. Sang.

Obituary.

JOHN COUPER, F.R.C.S.,

Consulting Surgeon to the London Hospital.

MR. JOHN COUPER, for many years surgeon to the London Hospital, died on April 30th. He was of ancient Scottish lineage, and studied medicine in the University of Glasgow, of which university his father was professor of *materia medica*. He was born in Glasgow, and received his preliminary education there, but subsequently went to Paris to perfect his knowledge of French. He graduated M.D. Glasgow, in 1858. In the following year he became M.R.C.S., and a Fellow in 1861. At Glasgow he attended the anatomy lectures and demonstrations of Professor Allan Thompson, and in London he was a student of Professor Ellis and Professor Sharpey. For a short time he went to Berlin and studied surgery under Langenbeck. Upon returning to London he became assistant surgeon and demonstrator of anatomy to the London Hospital, and was afterwards surgeon and lecturer upon surgery. He was one of the earliest promoters in London of the antiseptic system of surgery, a knowledge of which he had acquired from Lister at Glasgow. In fact, he established Listerian treatment at the London Hospital many years before Lister himself brought it to King's College. As a speciality he adopted ophthalmology and became clinical assistant to Crichton at Moorfields. At the meeting of the British Medical Association at Newcastle in 1870 he contributed a valuable paper upon the diagnosis of astigmatism by the ophthalmoscope. Upon retiring from active practice he went to reside first at Ellesborough, in Buckinghamshire, but subsequently removed to Falmouth, where he died and where he is buried.

Mr. Couper was of a retiring disposition. He catered little for popularity, but possessed many warm friends. Any medical views he had to express (and all his views were valuable) he communicated quietly to the transactions of one of the medical societies. Mr. Couper leaves to mourn his loss (a loss which will be felt far outside his family circle) a widow, three daughters, one of whom is married to the vicar of Ellesborough, and a gallant son, Colonel Duncan Campbell Couper, R.E., now at the front.

RICHARD GRAINGER HEBB, M.A., M.D.CAMB., F.R.C.P., Consulting Physician and Physician-Pathologist to the Westminster Hospital

WE regret to record the death, on May 12th, of Dr. R. G. Hebb. He was the eldest son of the late John Hebb of East Dulwich, and received his medical education at the University of Cambridge and King's College Hospital. He obtained the M.R.C.S. diploma in 1874, the M.D. degree in 1880, and was elected a Fellow of the Royal College of Physicians in 1891. In 1888 Dr. Hebb joined the teaching staff of the Westminster Hospital, and held for many years the two offices of physician and director of the pathological department. He was also pathologist to Queen Charlotte's Hospital, and for a long period secretary and editor of the Royal Microscopical Society, which recognized its indebtedness to him for the high standard maintained by its journal. He served as a civil surgeon in the Zulu war of 1879, and on the formation of the territorial hospitals received a Majority, but unfortunately his ill health prevented him from taking an active share in the work of the 4th London General Hospital, to which he was posted. He had been an examiner in medicine at the Royal College of Physicians and in the University of Cambridge; he held the office of reader in pathology in the University of London. In his more active days he was secretary of the old Pathological Society.

No member of the staff of the Westminster Hospital in the last thirty years exercised so great an influence over the students or was so universally esteemed for the precision of his knowledge, for his entire freedom from professional cant, and for his essential probity of character; to none did old students return in after years with more affectionate or grateful remembrances. As a physician in the out-patient department Dr. Hebb's teaching of physical signs was invaluable, for his perceptions were acute, his mind sceptical and almost entirely free from self-deception. But not every student could learn from him. In the wards in later years he attracted few besides his clinical clerks, but they certainly never failed for want of drilling in the elements of clinical observation. So it was with his systematic lectures; they were sound but unattractive. On the other hand, his demonstrations of morbid anatomy had become a tradition in Westminster; they were at one time largely attended by practitioners and colleagues as well as by the students; they were a continual delight; in themselves almost a liberal education.

Of his own work in pathology none but those who worked with him will ever appreciate its worth; he wrote but little, though his experience was great and his memory very remarkable. His modesty was so ingrained that the value of his observations was discounted by a reluctance to publish that owed something also to a rather cynical sense of the fleeting value of many contributions to the professional press. One who worked with him for years says that whilst his perceptions and descriptive powers were great, he was lacking in scientific imagination; hence it came about that many "discoveries" by other workers depended upon observations with which he had been familiar for years, but which he had failed to visualize in form or context communicable to the world. Scholar and gentleman, his teaching will long bear fruit in the work of generations of students who owe their fundamental ideas to him.

OWEN MEREDITH JONES, F.R.C.S.Eng., F.A.C.S., died on April 3rd at Victoria, Vancouver Island, where he practised for thirty years, and was long known as the leading surgeon in the west of Canada, enjoying besides great credit up and down the whole Pacific coast. Born fifty-five years ago at Carnarvon, and a student of the London Hospital, he went out to the coast in 1890 as surgeon of H.M.S. *Warspite*, and, leaving the navy, married and took

up practice. His wide knowledge, sound judgement, and great operative skill established him within the profession there as its leading consultant. His personal charm and sympathy endeared him to his patients. His devoted, unremunerated, and skilful attention to the wounded returned from the war, was crowned with remarkable success. As a doctor in Victoria writes: "The number of cripples he has restored is wonderful. . . . He certainly gave himself for the returned men, and they are grateful. . . . At a memorial service in Christ Church Cathedral on April 7th, nurses, doctors, and returned men occupied the middle of the nave, and the rest of the church was packed with patients. The Bishop preached." Dr. Jones will be greatly missed, not only from the Dominion and Provincial Medical Councils, but because of his great influence always exercised on behalf of the medical profession, and the action it knew to be needed in all matters of public health and morals. His eldest son, at the beginning of the war a second year medical student, is still serving in France with the C.A.M.C.

DR. JEAN JOSEPH PEYROT, surgeon to the Lariboisière Hospital, and lecturer on surgery in the University of Paris, died recently at the age of 74. He was a member of the Académie de Médecine, very popular as a teacher and distinguished as an operator. He was the author of many monographs, among them being one on the surgical treatment of intestinal obstruction, which is regarded in France as a classic. He contributed the volume on diseases of the neck, chest, and abdomen to the *Manuel de pathologie externe*, which under the name of the "Manuel des quatre agrégés," was the favourite textbook with the generations of students who followed each other in the French schools from 1885 to 1900. Of the four authors the only survivor now is Professor Kirmisson. The others were Reclus, who died on the eve of the declaration of war, and Bouilly, who fell a victim to cancer of the tongue some years before. Professor Peyrot was elected to the French Senate to represent the Dordogne in 1903.

COLONEL CHARLES FANCOURT WILLIS, C.B., Bombay Medical Service (retired), died at East Grinstead, Sussex, on April 28th, aged 63. He was born on May 22nd, 1854, and educated at St. Thomas's Hospital (taking the M.R.C.S. in 1875, the L.R.C.P. Edin. in 1877, and the M.R.C.P. Edin. in 1882) and at Durham University, where he graduated M.B. in 1879 and M.D. in 1887. After filling the post of clinical assistant at the Royal London Ophthalmic Hospital and at Newcastle Eye Infirmary, he entered the I.M.S. as surgeon on October 31st, 1879. He became surgeon-major on October 31st, 1891; lieutenant-colonel on October 31st, 1899; was placed on the selected list on May 24th, 1904; and promoted to colonel on November 14th, 1908, retiring on October 1st, 1913. Before his promotion he was civil surgeon of Satara, and as colonel was P.M.O. of the 5th (Mhow) Division. He served in the Egyptian war of 1882, in the battle of Tel-el-Kebir, and in the forced march to and occupation of Cairo (medal with clasp and Khedive's bronze star); in the North-West Frontier campaign of 1897-98; in the operations in the Kurram valley (medal with two clasps); and in the Tirah campaign of 1897-98; in the reconnaissance of the Khamana defile and action of November 7th, 1897; and in the operations against the Khani Khel Chamkanni tribe (mentioned in dispatches, G.G.O. No. 244 of 1898, clasp). He received the C.B. on June 19th, 1911.

PROFESSOR W. A. FREUND died in Berlin on December 24th at the age of 84. As a gynaecologist he distinguished himself by his work on extirpation of the carcinomatous uterus, an operation which, according to German sources, he was the first to perform. Of recent years he had devoted himself to the pathology of pulmonary tuberculosis and emphysema. His contributions to the mechanics of respiration are undoubtedly of high value.

DR. CHARLES BLAREZ, professor of chemistry in the University of Bordeaux, who died on March 3rd, was born in 1852 and received a teaching appointment in 1874. He published more than two hundred memoirs on pure or applied chemistry, and was the author of a course of organic chemistry in three volumes, and of monographs on the urine, and on milk. His last publication was a treatise on wines and spirits embodying the results of forty years' work.

Medical News.

THE pay of army nurses in Germany has been raised from 33.30 to 60 marks a month.

DR. HENRY JACKSON (Putney Hill) has been adopted as prospective Liberal candidate for the Putney, Roehampton, and Southfields Division.

THE Board of the Prussian Medical Chamber has declared in favour of an immediate rise of 50 per cent. in the pay of doctors.

THE Royal Dental Hospital, Leicester Square, has received a donation of £500 from the trustees of Smith's (Kensington Estate) Charity.

DR. ALEXIS CARREL, whose hospital at Compiègne was recently destroyed by German bombs, has been made a Commander of the Legion of Honour in recognition of his services.

THE annual general meeting of the Asylum Workers' Association will be held at the Mansion House, London, on Wednesday next, May 29th, when the chair will be taken by the Lord Mayor at 3 p.m.

PROFESSOR THOMS, Director of the Pharmaceutical Institute in Berlin, reports that efforts to grow opium in Schleswig have proved successful, and that the dried opium contained as much as 22 per cent. of morphine.

A COURSE of lectures to nurses on venereal diseases will be given by Mr. Leonard Myer, F.R.C.S., at St. Paul's Hospital, 13A, Red Lion Square, W.C.1, beginning on Tuesday, June 4th, at 5 p.m. The lectures are open free to nurses and midwives.

A COURSE of demonstrations and discussions on venereal disease will be held in connexion with the work of the Venereal Diseases Department of the Royal Institute of Public Health on Wednesday afternoons, at 2.30, beginning on May 29th.

IN Berlin complaints of the excessive moisture of the bread have led the bread control authorities to caution the bakers. In future a sample of bread must be tested at least once a week in every bakery, and the moisture must not exceed 47 per cent. in the crumb.

ON the recommendation of a meeting of the heads of the French army centres of neurology and of representatives of the French Neurological Society, a committee of neuro-psychiatric control has been set up by the French War Office to exercise general control over neurological and psychiatric centres, and to deal also with individual cases in which there is a difference of opinion as to convalescence, discharge, or military punishment.

A COMMITTEE of American poets has given to the Italian army an ophthalmic motor ambulance designed by Professor Busi of Bologna and Major Balestra. The equipment all packs into a trolley of the dimensions required by the railway authorities. It provides a small operating room with wooden walls and roof covered with impermeable canvas, and a waterproof tent mounted on iron frames with a rainproof roof which forms a reception room, and also on occasion a radiological cabinet and for ophthalmoscopic examinations, when it is covered internally with black cloth.

IN the article on Military Orthopaedic Hospitals, by Dr. W. Colin Mackenzie, which originally appeared in the JOURNAL of May 26th, 1917, and has now been republished in the compilation *British Medicine in the War* (British Medical Association, 429, Strand, W.C.2; price 2s. 6d.) a list was given of orthopaedic hospitals and centres in the United Kingdom. In this the 2nd Northern General Hospital, Beckett Park, Leeds, was described as having 250 beds. We are informed that since April, 1917, there have been 1,800 beds at this hospital, and that in the present year the number has been increased to 2,000.

THERE were only eight deaths from typhoid fever in army camps in the United States from September, 1917, to March, 1918, when there was only one suspected case under observation. In the Spanish-American war the death-rate from typhoid was 8.79 per 1,000; if that rate prevailed to-day the American armies, on the basis of 1,500,000 men, would have lost 13,000 to 15,000 from this disease alone. There has been no death from dysentery, and there are no cases now under observation. The annual death-rates per 1,000 during the six months ending March 8th, 1918, were: from pneumonia 5.2, meningitis (all varieties) 1.04, measles 0.096, scarlet fever 0.042, diphtheria 0.940, tuberculosis 0.15.

THE lighting, heating, and power order of the Board of Trade was discussed at the meeting of the Illuminating Engineering Society on May 14th. It was recommended that in order to avoid waste, carbon filament lamps should be discarded as far as possible in favour of metal filament (tungsten) lamps, and flat flame gas burners in favour of modern (low pressure) incandescent burners, and that in

large rooms a single gas-filled (half-watt) lamp could advantageously replace a number of small filament lamps of less candle power. It was recommended also that wrappings of silk or coloured paper which absorb a great deal of light should be replaced by diffusing or prismatic glass devices or cardboard or enamelled shades with white interiors.

THE annual general meeting of the London and Counties Medical Protection Society, Limited, was held at the offices of the Society, 32, Craven Street, W.C., on May 15th. Colonel L. C. Bensley, Chairman of Council, who presided, said that the membership of the society had decreased to a very small extent during the year, but the financial position continued to grow stronger. Five hundred members had received advice and assistance, and about one hundred of these cases have been referred to the society's solicitors. Many of the cases were concerned with the administration of the Insurance Acts, with respect to which many vexatious matters were continually arising; others, a considerable number, had to do with matters arising out of military and naval service. The society had been very successful in its law suits, and several unqualified practitioners had been prosecuted and penalized. Dr. Owen Fowler, the acting treasurer, said that the investments of the society at the end of 1915 stood at £14,614, and at the end of last year, after a considerable sum had been written off in order to bring them down to current market values, they stood at £20,242. The President, Major-General Sir John Rose Bradford, was re-elected, as were all the other officers, and the four retiring members of the council.

A NEW charter has come into force this year at Cincinnati placing all the medical, scientific, and nursing work in the new city hospital under the direction of the university. The medical director of each department will be the professor in the corresponding department of the medical college, and the board constituted by these directors will nominate, through the president, all members of the staff of the hospital, including the superintendent, who will be the general executive and business manager. The superintendent will select all the other employees under the rules of the Civil Commission of the City. By this arrangement the hospital is removed from the sphere of politics and all the facilities of the hospital are made available for purposes of education and research. The new building of the medical college, which stands on a site of twelve acres immediately opposite the hospital, has recently been completed, and is, we learn from *Science*, now occupied. This gives Cincinnati a complete plant for medical teaching and research which has cost over £1,000,000. The medical college is a regular department of the university, which pays all its expenses. The city will continue to pay the general working expenses of the hospital, including heating, lighting, food, and engineering. The total cost to the city of the combined medical college and hospital plant will be, without including income on endowments, approximately £140,000 a year.

BIJL (*Nederl. Tijdschr. v. Geneesk.*, December 15th, 1917), writing of the recent epidemic of cerebro-spinal meningitis in Holland, states that 54 cases were recognized in 1915, 226 in 1916, and 449 in the first six months of 1917. Expert assistance in making lumbar punctures was freely given to local doctors, and apparently the *Diplococcus intracellularis* was found in all the cases notified. A number of cases notified simply as (idiopathic) meningitis, in which no lumbar puncture was made, may have been instances of the epidemic form, for isolated cases of meningitis in remote villages were often found unexpectedly to be due to the diplococcus. This is one reason for thinking that a number of cases must occur annually in Holland and be mistaken for non-epidemic meningitis, or even for enteric fever, influenza, or other febrile diseases. The mortality of epidemic cerebro-spinal meningitis was 54 per cent. in 1916 and 43 per cent. in 1917, a fall due either to treatment or to the recognition of mild and atypical forms. The mortality from all forms of meningitis has steadily fallen in Holland from 3.96 per 10,000 in 1901 to 1.41 in 1916 in spite of the epidemic. A rise, of course, is now to be expected. The epidemic character of the illness is not pronounced. *Bijl* admits that 11 cases occurred in one small place and 30 in another, but in 1916 there were fifty-one districts in which only one case occurred, and in 1917 72 per cent. of the cases were solitary. Small epidemics of so-called sporadic idiopathic meningitis, of the form regularly occurring in Holland have often been noted. Thus, in small places, five, seven, and nine cases have occurred at the same time. This is a second reason for thinking that so-called epidemic cerebro-spinal meningitis is always present in Holland, unrecognized maybe, for the diagnosis can only be made bacteriologically.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulato*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES AND ANSWERS.

DR. LEONARD HILL, F.R.S., writes: It has been announced that I am to give a lecture at the Institute of Public Health, Russell Square, on July 3rd. Will you allow me to state that I have reconsidered this matter and this lecture will not be given?

EARLY THERAPEUTIC USE OF ANIMAL EXTRACTS.

DR. LOUIS MACPHERSON (Edinburgh).—The *locus classicus* as to organo-therapy in antiquity is the 28th Book of the encyclopaedic treatise on natural history by the Elder Pliny (23-79 A.D.). Of this work there is a fine English rendering (*The Histories of the World Commonly called The Natural Historie of C. Plinius Secundus*, Translated into English by Philemon Holland, Doctor in Physicke, London, 1601). The ancients left little untold in the domain of animal extracts, and their enterprise was limited only by their ignorance of anatomy. Dioscorides, who flourished in the first century of the Christian era, in his great work (*De materia medica*, Libri V, Recensuit etc. Curt Sprengel: *Medicorum Graecorum Opera*, Leipzig, 1829-30) gives a large place to animal extracts. But it was not till the middle ages that organo-therapy received the freedom of the medical city. One of the chief sources on the subject is Mesuë, an Arabic writer as to whose identity there is some mystery. It would seem that two different authors had become fused into one. Mesuë the elder (A.D. 777-857) was physician in ordinary to the famous Caliph Haroun-al-Raschid of the *Arabian Nights*, and afterwards to Al-Mamoun. His aphorisms were gathered into a volume which was translated into Latin under the title *Selecta Artis Medicæ*. Down to the fourteenth century he was constantly quoted by medical writers under the name of Janus Damascenus (John of Damascus). Mesuë the younger (circa 1015 A.D.) is said to have been a pupil of Avicenna, but there seems to be some reason to believe that a Latin compiler of the tenth or eleventh century assumed the name. His writings on *materia medica* formed the basis of the western pharmacopoeias, and were consulted up to the beginning of the eighteenth century. Organo-therapy was practised, on the lines laid down by Mesuë, by Rhazes and Albucasis in the tenth and Avicenna in the eleventh century. In the twelfth century the teachers of Salerno followed the Arabians in the use of animal extracts. In the thirteenth century Albertus Magnus, in his *Liber Secretorum de virtutibus herbarum, lapidum et mineralium* (1250), and Guy de Chauliac, in his *Grande Chirurgie*, written in 1363, speak of the use of animal extracts and secretions. Among other writers who recommend them may be mentioned Fernel, in his work on therapeutics (1558); Jerome Cardan, in *Ars Curandi Parva* (1566); Liébault, in *Quatre Livres des Secrets de Médecine* (1573); Pietro Andrea Mattioli of Siena, who wrote a commentary on Dioscorides (1572); Jean de Renou, in his *Dispensatorium* (1608); Nicholas Lémy in his *Pharmacopée* (1689); and *Dictionnaire des Drogues* (1693); Pomet in his *Histoire générale des Drogues* (1694); and Lientaut in his *Précis de la matière médicale* (1748). A more accessible source is Alfred Franklin's *La Vie privée d'autrefois: les médicaments* (Librairie Plon, rue Garancière, 10, Paris, 1901). Nicolas Culpeper (1616-54), in his *Physicall Directory* (1649), an unauthorized translation of the pharmacopoeia issued by the College of Physicians, ridicules not unhappily the animal remedies included in that work. The pharmacopoeias of the sixteenth and seventeenth centuries recall the hell broth of the witches' cauldron in *Macbeth*. Traces of these horrors are to be found in dispensaries published in this and other countries down to the nineteenth century. Gordon Cumming, in his *Wanderings in China*, gives numerous examples of the use of disgusting remedies of animal origin in the Celestial empire, and an important chapter is devoted to medicine in Captain Bourke's *Skatalogical Rites of all Nations* (see BRITISH MEDICAL JOURNAL, June 11th, 1892).

p. 1263). In a series of articles on organic medication before Brown-Séquard, published in the *Archives Cliniques de Bordeaux* (February, March, April, 1898), Dr. Félix Brunet, a medical officer of the French navy, gives a historical review of the subject with a copious bibliography.

LETTERS, NOTES, ETC.

PHYSICAL DETERIORATION OF BOYS UNDER WAR CONDITIONS.

MR. ROBERT R. HYDE (Director of the Boys' Welfare Association, Sanctuary House, Tothill Street, Westminster, S.W.1.) writes: Much attention has been devoted to the above question during the last two years, and in spite of the abnormal conditions under which industries are being carried on, many attempts have been made to grapple with it. The evils can only be counteracted by personal influence and leadership (the suggestion of Dr. Howard Distin in your issue of May 11th, as to the limitation of wages, involves many serious issues, and is impracticable). In order to supply such forces where they can be used to the best advantage—that is, in workshops and factories—a scheme of boys' welfare supervision has been adopted by some hundreds of leading employers throughout the country. Results, so far, have been excellent.

SOLDIERS' TRACT ON VENEREAL DISEASES.

MR. WILLIAM JONES (librarian, the Liverpool Medical Institution) writes that during the past two years the Institution has distributed 250,000 copies of a pamphlet written in plain non-technical language for young soldiers, warning them of the dangers and disabilities incurred by contracting these avoidable diseases. The tract has proved to be of great acceptance after lectures or talks to the men on these subjects. Inquiries are invited from C.O.'s, members of the R.A.M.C., chaplains, and social workers who would care to have a number of copies sent for distribution. Letters addressed to the librarian, Liverpool Medical Institution, will receive prompt attention.

THE HUMAN AND THE EQUINE FOOT.

MR. T. S. ELLIS (Gloucester) writes: Under the heading of "Feminine Equinism" is recorded in the *JOURNAL* of March 30th a discussion at the French Academy of Medicine on the effect of the high-heeled shoe, and on a deformity called "equinism, the horse foot, or hoof foot." I do not see how a resemblance to a hoof can be so caused, but I ask permission to tell once more how a recognition of the close analogy in the formation of my own foot and that of the horse was to me of inestimable value.

More than half a century ago my own foot was crushed between the body of a horse and the stones of a street crossing. The astragalus was forced inwards (subastragaloid dislocation) and the middle cuneiform upwards so as to project on the surface of the foot. Both deformities are still manifest. After some months I was able to walk, wearing a costly and very uncomfortable apparatus; the prospect of having to go through life under such conditions weighed heavily upon me. I happened to see a horse rear to an unusual height, and I marvelled at the strain there must be on the ligaments which bound together the bones which form the fetlocks. The backward and downward thrust must be enormous, such as no ligaments could stand. On reflection I thought that the tendon of the great flexor muscle, coming down from the haunch past the hock (the anatomical heel) and subtending the curve of the fetlock, must have a bow-string or tie-rod effect upon it. This would relieve the strain on the ligaments. I thought, too, if this be so, is not the tendon of the flexor longus pollicis in my own foot the bow-string or tie-rod of my plantar arch? And, further, is it not possible that a vigorous and prolonged action of this muscle would restore my flattened foot? Perseverance, pain being disregarded, soon brought some reward, but the story of the restored arch would be too long to tell here. Enough to say that I never again wore any kind of apparatus, and for many years no one who did not know would suppose that I had ever been lame. In my book, *The Human Foot*, and elsewhere I have tried to convince others of the practical importance as well as scientific interest of foot physiology. How little it is recognized is shown by the discussion at the French Academy, when it was thought worth while to pass "a resolution declaring that the fashion of very high heels was injurious and absurd." Moreover, the British Government supplies the public with boots having heels 2½ in. high with toes pointed in the middle line, in disregard of anatomy, of the great human characteristic of asymmetry of form and of difference in function between the great toe and that of the smaller toes.

THE OLDEST ENGLISH HOSPITAL.

DR. S. D. CLIPPINGDALE points out that Miss Mary Clay, in her book on *The Mediaeval Hospitals of England*, defines these early institutions as "houses for wayfarers, sick, aged and infirm, insane and lepers (founded before 1547)." The earliest dates of hospitals in England mentioned by her are 1087, St. Nicholas, Nantwich; 1089, St. John the Baptist and St. Nicholas, both in Canterbury. In 1100 followed St. Leonard Bentley, Derbyshire, and St. Cross, Bath. The date of the

foundation of St. Bartholomew's, Rochester, is given as 1108. Dr. Clippingdale would derive the word "hospital" from hospitium, which meant a place to receive guests. Murray (*N.E.D.*) infers that it came into English from the French, which got it from the mediaeval Latin "hospitale," the neuter singular of an adjective meaning really hospitable. Murray recognizes that the onrrent use of the word "hospital" is confined to an institution for the care of the sick and wounded. Dr. Clippingdale refers incidentally to the fact that the hospital established in Jerusalem by the knights of St. John in 1112, which was capable of receiving 2,000 persons, had its infirmary. So did many religious institutions. Murray states that "infirmary" was the common English word for a public hospital in the eighteenth century, and the use has survived very generally, we believe, in Scotland as well as in many large English towns.

THE FIRST INCUBATED BABY.

It is said that the first instance of successful rearing in an incubator was a premature infant who grew up to be a distinguished member of the medical profession. The case is related by Adrien Baillet in *Le jugement des Savants sur les principaux ouvrages des auteurs* (Paris, MDCCXXII). Fortunio Liceti, a man of encyclopaedic knowledge, was born on the coast of Genoa on October 3rd, 1577, two hours after midnight, during a voyage which his parents made from Recio, their native place, to the town of Rapallo, where his father intended to settle as a practitioner of medicine. The fatigue of the journey, combined with the fury of a storm which they encountered in passing near Cape Portofino, brought on labour pains in his wife, which he considered to be false in spite of all the mother could say to persuade him that she was not far off the seventh month. The babe, which was not larger, it was said, than the palm of the hand, was brought alive to Rapallo, where it was shown to Jerome Bardi and other physicians. It was found that nothing essential to life was lacking, and the father undertook to complete the work of Nature by the same artifice that is used to make chickens hatch in Egypt. He instructed a nurse, and had his son placed in a properly fitted oven kept at a uniform temperature exactly measured with the thermometer. The child lived nearly eighty years and composed eighty different works. In addition to this account which Baillet found in the work of Michael Giustiniani (*Degli Scrittori Liguri*), and which is quoted by Sterne in *Tristram Shandy*, where the length of the fetus is given as 5½ in., there is another which represents Liceti as simply having been reared in a box lined with cotton. It is not possible to determine which of the two accounts is the more authentic, but the oven heated in an uncertain way, in which the atmosphere must have been dangerously dry, and the absence of data as to the manner in which feeding was carried out, render the first story somewhat suspect to those who know the minute care with which a child in an incubator has to be surrounded. Rearing in cotton under similar conditions would not be more easy. Liceti was successively professor of philosophy at Pisa and Padua, physician at Bologna, and professor of medicine at Padua. It is true the eighty books with which he is credited by his biographers rather suggest that, like the great Lipsius, he composed a work on the day he was born, but there are certainly more than fifty which bear his name. In addition he corresponded with the most intellectual men of his day, and his letters fill many volumes. He died in 1657.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

Subscriptions to the Second Appeal.

The following subscriptions and donations to the Fund have been received during the week ending May 18th:

	£	s.	d.		£	s.	d.
Dr. Andrew T. Ross	1	1	0	Dr. J. N. Gardiner	1	1	0
X. Y.	1	0	0	Dr. Henry Whitehouse	1	1	0
Dr. Reid	1	1	0	(also 10s. monthly)	1	1	0
Dr. S. G. Sloman	5	0	0	"Subscriber"	0	10	0
Dr. Mary A. Smith	0	10	6	Dr. Geo. McIntyre	2	2	0
Dr. J. S. Fraser	1	1	6				

Subscriptions to the Fund should be sent to the Treasurer, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *restante* letters addressed either in initials or numbers.

THE CARE OF THE TUBERCULOUS SOLDIER.*

By MAJOR P. HORTON-SMITH HARTLEY, C.V.O.,
M.D., F.R.C.P.

HONORARY ADVISER ON TUBERCULOSIS TO THE MINISTRY OF PENSIONS;
SENIOR PHYSICIAN TO THE BROMPTON HOSPITAL FOR
CONSUMPTION AND DISEASES OF THE CHEST.

In this paper I propose to bring before the conference the steps which are being taken in Great Britain to treat and assist the soldier who has acquired tuberculosis in the service of his country or whose disease has been aggravated thereby. Our allies may have adopted methods which differ in part at least from those in vogue in this country, and a consideration of such differences may be of material value in indicating the directions which our further efforts should take.

A year ago, in an article published in the journal. *Recalled to Life*,¹ I sketched out the proposals and plans which the Ministry of Pensions then had in view. In the present paper, based on my former article, I propose to bring the position up to date, to state what is being done and to indicate what there remains to do.

The problem is a vast one. Up to the end of last year about 20,000 men had been invalided from the British army suffering from pulmonary tuberculosis, and each year the war continues large numbers will be added to the total. The national importance of the problem is also heightened by the fact that too often a case entails suffering, not only upon the patient himself, but also upon those near and dear to him, thus augmenting suffering and greatly increasing the cost of treatment.

Need for Careful Examination of Recruits.

In considering the subject, we must first ask ourselves whether every care is exercised to limit the problem by seeing that men already suffering from tubercle are not admitted into the army. In the past this has not been the case. Men have been passed into the army who had previously been inmates of sanatoriums and had suffered from consumption. Of these, not all break down again, the result depending much on the hardships to which they may or may not be exposed, but many certainly do succumb after a longer or shorter interval and are invalided from the service, thus entailing great expense to the country in treatment allowances and pensions. It is clearly wiser, therefore, to exclude such men from the army, leaving them to continue their work, which may be of great value to the country, in their more sheltered civilian capacity. Great care must be exercised, therefore, in examining recruits. Histories of previous pleurisies and haemoptysis must be carefully inquired into and investigated, and the assistance of tuberculosis officers and others who have experience in the diagnosis of diseases of the chest invoked in any case where doubt or difficulty arises. The need of care in this respect is now more generally appreciated, but it must be constantly borne in mind, in the interest both of the country and of the individual recruit.

But if all such cases of obvious tuberculosis could be eliminated from the army we should still have a vast problem to deal with, for to the war itself must be attributed a large proportion of the cases of phthisis with which we have to deal. Modern research teaches us that nearly every adult is already infected with tubercle. Under normal circumstances the natural immunizing processes are sufficient to prevent the spread of the infection, and most of us carry the poison through life without harmful result. But under the strain of active service it is different. The soldier's strength becomes sapped by exposure and strain and his vitality diminished, and under these conditions the tuberculous focus, which might otherwise have remained for ever dormant, wakes into life, and signs of active disease, for the most part affecting the lungs, make their appearance.

Direct infection has no doubt also played its part in the spread of tuberculosis which we are considering. The close proximity of man to man, inseparable from life in tents and the unavoidable overcrowding sometimes met with in billets or huts, must have presented many oppor-

tunities for massive infection and consequent danger when a case of consumption has developed under such conditions.

Need for Early Diagnosis.

The next point which must be borne in mind is the necessity for early diagnosis, when once signs of pulmonary tuberculosis begin to manifest themselves, if we are to obtain the best results from treatment and prevent the further spread of the disease. In view of the insidious onset of the malady in so many cases this is by no means easy, especially under conditions of active service. The members of the Royal Army Medical Corps must, therefore, ever be on the watch for the disease, and when signs of lassitude, cough, and wasting make their appearance the man should at once be placed under observation, his temperature registered, and the sputum tested, not once, but many times. If this is done, in most cases the disease will be recognized early, and appropriate treatment will have the best chance of success.

Let us now consider what is being done in this country to secure for the soldier who has developed phthisis the treatment best suited for him in the different stages of his illness, and in the following pages pulmonary tuberculosis or phthisis will be especially considered, this being the chief problem with which we have to deal. It should be added, however, that treatment for surgical and other forms of tuberculosis is provided by the National Health Insurance Commissioners.

Treatment of Early Cases of Pulmonary Tuberculosis : Sanatorium Treatment.

As soon as it is evident that the patient is suffering from phthisis, or even when this is strongly suspected, he is sent home to one of the military hospitals in this country. If there is no doubt about the diagnosis he comes before a medical board, and in due course is invalided from the army, his further treatment being undertaken by the civil authorities. Before being discharged, however, from the military hospital, and in order to avoid delay in procuring him suitable treatment, steps are taken to arrange with the National Health Insurance Commissioners for his admission to a sanatorium, if he be an early case, or to a hospital if his disease be more advanced—every discharged soldier, whether insured or not, whose tuberculosis has, in the opinion of the invaliding board, been either "caused" or "aggravated" by military service, being now entitled, under arrangements recently made, to such form of treatment as his case requires. For this purpose a form (National Health Insurance, A.F.O. 1835), entitled "Application for Sanatorium Benefit on Discharge from the Army," is filled in, giving the man's name and intended place of residence on discharge, together with certain medical details in regard to his case. It is signed by the officer in charge of the military hospital, and forwarded to the National Health Insurance Commissioners of England, Scotland, Ireland or Wales (at the addresses given on the form), according to the part of the kingdom in which the applicant proposes to reside. Arrangements are then made by the Commissioners (under financial agreement between the Commissioners and the Treasury) whereby the soldier, now invalided from the service, is transferred, provided he be an early case and accepts the treatment, to a sanatorium, and this is, so far as possible, the institution with which the Insurance Committee of his place of residence has habitually made arrangements, and consequently, as a rule, not far from the patient's home.

Before leaving the hospital the case is also brought to the notice of the Local War Pensions Committee of the area in which the man will eventually reside. These bodies have now been established all over Great Britain, and one of their most important duties is to keep in touch with discharged soldiers and to assist them when in difficulty, and to obtain for them such treatment as they may from time to time require.

In the early period of the war not a few men refused sanatorium treatment in their anxiety to return home and see their relations and friends, from whom they had been long separated. This difficulty has been overcome by granting the soldier a fortnight's leave on full pay and allowances after leaving the military hospital and before entering the sanatorium. In other cases refusal of treatment may have been due, in part at least, to insufficient

* A paper read before the Inter-Allied Conference on the After-care of Disabled Men.

care on the part of hospital authorities in impressing upon the patient the necessity of accepting sanatorium treatment in the early stages of his disease. To give another chance to such patients, the Ministry of Pensions has made financial arrangements with the Insurance Commissioners whereby, if such a case is brought to their notice by the Local War Pensions Committee or otherwise within six months of discharge from the army, sanatorium treatment will be given with as little delay as possible.

Allowances during Sanatorium Treatment.

It was clearly useless, however, to expect men who may not feel very ill, and who are capable of some work, to accept sanatorium treatment should they feel that their families are in want as a result of their absence from home. It was decided, therefore, that whilst a man is at a sanatorium he shall be considered "totally disabled," and he is in consequence given an allowance at the maximum rate of pension, which, in the case of privates, amounts to 27s. 6d. a week (less a deduction of 7s. per week in respect of maintenance), together with a separation allowance of 13s. 9d. per week for wife, and of 6s. 8d. per week for the first child, 5s. for the second, and 4s. 2d. for the third and subsequent children, provided they are under 16 years of age. It may be added that, as provided by Article 4 of the Royal Warrant, if a man refuses to carry out treatment without good and sufficient reason, he is liable to forfeiture of anything up to one half of his pension.

Treatment at the Sanatorium.

During a patient's stay at a sanatorium he is kept in bed for a time, and as soon as it is clear that there is no pyrexia (or as soon as this has passed away), he is, at all well run sanatoriums in Great Britain, treated by a system of graduated exercise—the German Liege-Halle system, of which rest is the chief factor, having never found much favour in this country, except, of course, in febrile cases. The exercise prescribed is at first walking only, but such a monotonous occupation is gradually replaced by light and useful work, increased little by little until at last, before their discharge, the most favourable cases do six hours' hard navy work a day.

As a result of this treatment the patient, when the course is finished, returns home with his muscles in good condition and able to resume work, but he must continue to carry out at home, as far as possible, the open-air lines of treatment which he has learnt at the sanatorium, if he is to maintain his health. He must also be careful not to overtax his strength in the early months after his discharge, and only gradually return to full work, and even then he should be in a position to take a day off from time to time, and to rest if he should not be feeling quite himself. This has been the great difficulty with the sanatorium patient in the past, his "benefit" payment from his friendly society ceasing as soon as he returned to work of any kind, even for an hour or two a day, so that it has been incumbent on him to work at once "full time" if he is to earn his weekly wage and thus to support himself and his family. The ex-soldier is, however, in a happier position. The Minister of Pensions, recognizing the position, and appreciating the fact, accepted by all life assurance societies, that a man who has had consumption can never be regarded again as the equal of one who has not suffered from this malady, has taken steps in conjunction with the Ministry of National Service to see that all medical boards at which the soldier's pension will hereafter be reviewed, shall be furnished with the opinion and advice of the medical superintendent of the sanatorium (if the patient be still at the sanatorium when the board is held), and afterwards of the tuberculosis officer, who will have the future care of his case, and who will be conversant with his condition, so that the man's pension will be properly graded according to his working capacity, in so far as this is affected by his tuberculous disease. This is a matter of vast importance, and the Minister's wise and just decision will in future afford the patient a greatly increased chance of maintaining arrest of his disease.

Advice as to Work and Occupation after Leaving the Sanatorium.

It may at this point be of value to refer to the important question as to the kind of work which the patient should

undertake on leaving the sanatorium, and the advice which should be given him in this respect, for upon a right decision in this matter his future health will largely depend. He will be a man who has probably had some former trade or occupation, and if this be not obviously injurious, the question often to be settled is as to whether he should return to his former occupation, which will probably offer him a good wage, even though this may necessitate his living in a city under "urban conditions." Some recent observations on the after-histories of patients who have left the Brompton Hospital Sanatorium, at Frimley in Surrey, are very instructive in this respect.² They would seem to show that the outlook of patients with limited disease who leave the sanatorium with their malady arrested, and who return to urban life under fairly satisfactory conditions, is infinitely less hopeful than the outlook of similar cases who have been able to effect a change of environment into the country, and sometimes a change of work. If possible, therefore, a return to town life should not be sanctioned, but in advising on the matter we must ever bear in mind the wage to be earned from any form of work proposed, for it is of paramount importance that the man should obtain from his work, supplemented by his pension, a sufficient income to enable him to be properly fed and adequately housed. Without this the most ideal climatic conditions will not save him from a breakdown and renewed activity of his disease. The work also must not be of too arduous a nature.

For this reason the advice so often given, urging the patient to give up his former occupation and to undertake, without any previous experience or training, the work of an agricultural labourer, is generally mistaken. The wages are not high, the housing accommodation is too often very poor, and the work is often exceedingly arduous. It is carried on under conditions of great exposure, and the hours at certain seasons are very long. As a result, only the exceptional case can stand it without breaking down, and it is not suitable for the average consumptive on leaving the sanatorium. We may add, too, that it is not a life which possesses great attractions for the former town-dweller.

In many cases, owing to the difficulty of finding a totally new occupation, and the fact that under such circumstances the man will at first be untrained, and therefore capable, for a time at least, of earning only a low wage, probably the wisest course is to allow the patient to return to his former avocation, provided it be not, like coal-mining, clearly and obviously unsuitable to a consumptive patient, *changing, however, the environment whenever possible.* To quote from my former paper:

Thus, a clerk may return to his clerical work, but should obtain, if possible, a post in the country or at the seaside. Similarly, a bank clerk may often be transferred to a country or seaside branch. A railway porter should apply for removal to a country station, and a policeman to a suburban division, while a carpenter may obtain work as an "estate carpenter." In this way the patient is often enabled to return under good conditions to his former work, in which he is skilled, and can thus earn a better income than if he attempted a change of occupation. He has accordingly more money to spend in food, his vitality remains good, and his chances of keeping well are increased.

Should it be necessary, however, to find a fresh occupation for a patient, then one must be chosen in which the work is carried on under satisfactory conditions, and as much in the open air as possible. Whenever possible, too, the employee should be to some extent his own master in regard to the number of hours worked each day, and the ability to take a day off from time to time, should he not be feeling quite up to the mark. In this way his strength is conserved, and the danger of a breakdown lessened.

In deciding on the exact occupation the various trades should be considered. For example, in the building trade the work of a painter or decorator, a builder, a bricklayer, a carpenter or joiner may all be permitted, by preference, however, in a smaller rather than a larger town. Similarly, wood-carving or wood-road laying may be suitable. In the transport trades a man might take up the work of a coachman, cab-driver, chauffeur, taxi-cab driver, motor-van driver, or motor cleaner; but experience shows that the work of an omnibus or tram conductor or driver is too arduous in these days of large vehicles and rapid driving. Railway ticket collecting and some forms of mechanical work on the railways should also be suitable.

Certain lighter forms of work on the land may also be recommended, such as market and flower gardening, fruit growing, hurdle-making, forestry, and woodman's work. The work of a gamekeeper, park ranger, park attendant, or lodge keeper is also excellent, but the number of such posts is limited. Other light occupations which may be mentioned are those of a

traveller, an insurance or commission agent, rent collector, canvasser (though in individual cases they may involve too many hours' walking), commissionaire, and bookstall attendant.

Should in any case the larynx be affected, an occupation involving much talking is to be avoided. Similarly, if the case be one liable to superadded attacks of bronchitis, then the less exposed occupations must be chosen. Window cleaning is not to be recommended, owing to possible risk of hæmorrhage.

The above list of occupations is by no means exhaustive, and is given only as an indication of the kind of occupation which may be recommended. If the ex-soldier's occupation is thus changed, it is probable that, for a time at least, there may be some loss of income, but, as already pointed out, this will be taken into account when his pension is reviewed from time to time, in so far as the medical board is satisfied that the man's physical condition is affecting his normal working capacity.

The Value of Health Visitors.

A change of environment, and sometimes of work as well, such as we have recommended, is not, however, to be accomplished by the stroke of a pen, and certainly not without taking all the circumstances of the man's family and home surroundings into consideration. For this purpose the services of a health visitor who has had training in social work, as well as practical experience at a tuberculosis dispensary, have been found of great value. It is her duty, while the patient is at the sanatorium, to visit his home and to make herself acquainted with the circumstances of his family. Should the medical superintendent of the sanatorium, after becoming fully conversant with the man's case, advise a change of work and environment, it is her privilege, in co-operation with the Local War Pensions Committee and the Tuberculosis After-care Committee, where such exists, to help him to effect the change, and very often her efforts will be successful. Later it will be the duty of the health visitor to visit the home from time to time, to see that proper precautions are carried out and that the man reports himself to the tuberculosis officer for examination at regular intervals. She will also arrange for the examination of contacts, and give friendly counsel in regard to the occupation chosen for the children, bearing in mind their predisposition to the disease.

Health visitors such as these already exist in certain areas and are doing excellent work, and a proposal is now being considered by the Ministry of Pensions and the Local Government Board to establish them generally throughout the country, so that the tuberculous soldier may obtain the maximum benefit from the treatment which he is entitled to receive.

Treatment of Advanced Cases.

After the patient has returned to work he is kept under observation by the tuberculosis officer, the health visitor seeing that he reports from time to time for medical examination. Should he show signs of breaking down, it is the duty of the tuberculosis officer to obtain for him, through the Insurance Committee, the treatment which his case requires—possibly a 'further course of sanatorium treatment, possibly treatment at home under his panel doctor, or possibly a spell of hospital treatment.

A time will come, however, in most cases, when the disease becomes advanced, and the patient bed-ridden and totally incapacitated. He is now in urgent need of medical treatment and careful nursing, and it is a time when, in the interests of his wife and family, in order to avoid the risk of massive infection, which at this stage of the disease is a grave one, he should receive institutional treatment. Such cases in the past have too often drifted into the Poor Law infirmaries—when they have not declined such treatment and elected to remain at home, with all the attendant risks and consequences of their families—since provision for such cases is not generally made under the Insurance Act. To prevent this unsatisfactory state of affairs, provision of "advanced beds" has been made by the Minister of Pensions.

Arrangements in the first place have been entered into with the Metropolitan Asylums Board, whereby up to 150 beds have been made available in the hospitals under their charge in the various London districts for the treatment of such cases, which must be certified as "In need of residential treatment, though not likely to recover a reasonable degree of working capacity." At present three wards, containing 64 beds, have been opened, and as the necessity arises more will be placed at the disposal of the Ministry. The Metropolitan Asylums Board is responsible for the maintenance and treatment of the patients, the actual cost being paid by the Ministry. The arrangement has

worked excellently, and the Ministry is indebted to the Metropolitan Asylums Board for the valuable help which it has given in this matter. The patients have been admitted without delay, have been well and sympathetically treated, and not a few have stayed until they died in the institution. As the patients for whom these beds are assigned are drawn from London and the adjoining counties, they are not too far removed from friends, who can visit them from time to time, and a sense of isolation is thus avoided.

In other parts of England beds for advanced cases are also being provided. At the Walker Gate Sanatorium, Newcastle, and at the Cottingham Sanatorium, near Hull, 15 beds at each institution have been placed at the disposal of the Ministry, and at Bierley Hall, Bradford, and at the Fazakerley Sanatorium, near Liverpool, 60 and 30 beds respectively will shortly be available. At the Cambridgeshire Tuberculosis Colony, at Papworth Hall, some ten miles from Cambridge, the Pensions Ministry has also obtained a lien on 40 beds, some of which will be used for advanced cases. In addition, small pavilions to accommodate 12 beds each (in the case of Birmingham 24) are being erected in the grounds of existing hospitals and sanatoriums—namely, at St. Helens, in Lancashire, at Birmingham, Derby, Southampton, Bristol, and Exeter, and these will shortly be in occupation. Towards the cost of the erection of these buildings the sum of £10,000 has been generously placed at the disposal of the Ministry by the British Red Cross Society and the Order of St. John of Jerusalem. The pavilions so erected, as well as the beds at the various institutions referred to above, will serve not only the urban districts mentioned, but also the surrounding areas, and the patients admitted will not be separated too far from relatives and friends.

It is interesting to note that in France our allies recognize equally with ourselves the importance of providing hospital treatment for the advanced tuberculous soldier, alike in the interest of the patient himself and with a view to preventing the spread of infection to his family, in this last and most dangerous stage of the disease, and that the erection of a hospital for this class of case is in contemplation by the French Red Cross Society.

Farm and Training Colonies.

In conclusion, I must say a few words in regard to farm and training colonies. In discussing the question of the work which a patient should take up after leaving the sanatorium, I have indicated that there are certain occupations, such as coal-mining, which, though not unhealthy in themselves, are clearly unsuitable for the consumptive. If the patient's previous occupation has been of such a nature, he must, therefore, perforce effect a change. A certain number of such patients may have had some previous knowledge of the land and be desirous of undertaking training in agricultural work, and for such as these farm colonies are being started. To these institutions the selected patients will be drafted direct from the sanatorium, and at them they will stay a year, since adequate training cannot be given in a shorter time. During this period treatment will be continued, and the patient will also be trained in agricultural work, market gardening, pig-keeping, bee-keeping, poultry-farming, and dairy work, together with rough carpentry and metal work, so that at the end of his stay he will be in a position to undertake work on the land either in this country or the colonies, or if he should eventually find other work, he would possess the requisite knowledge to cultivate an allotment with profit and success. During his year's stay the arrest of his lung disease should be rendered more secure.

Such colonies are a new development and are still in the experimental stage, for it is not known whether, under the existing conditions of the labour market, when well-paid work is so easy to obtain, men will be content to remain a year at a colony, nor can it be said as yet with certainty how far the after-history of a colonist, trained and treated as above, is better than that of a man who has simply passed through the full course of graduated labour at a first class sanatorium, and returned to suitable work in good environment at the end of his three or four months' treatment. This being so, and as the cost to the country of treating and training a patient at such a colony for a year will be considerable, the Ministry of Pensions is proceeding carefully in the matter, but if such colonies prove successful the scheme will no doubt be extended.

At present four such colonies are being started. They are as follows:

1. The Red Triangle Colony, at Kinson, five miles from Bournemouth, under the management of the Young Men's Christian Association. (21 colonists.)

2. The Cambridgeshire Tuberculosis Colony, at Papworth Hall, some ten miles from Cambridge, at which the Ministry

has a lien on 40 beds, some of which will be available for colony patients.

3. The colony now being inaugurated through the generosity of Mr. R. A. Pilkington in connexion with the Liverpool Sanatorium, in Delamere Forest. (30 colonists.)

4. The Royal Victoria Farm Colony, Polton, near Edinburgh, originally started by Sir Robert Philip. (Possibly 100 beds.)

Each of these colonies will probably develop on slightly different lines, as dictated by local conditions. At Kinross and at Edinburgh the colonies, as at present advised, will be purely agricultural. At Delamere Forest it is hoped that, through the good offices of H.M. Office of Woods and Forests, training in forestry will also be given, for which there will be full scope after the war, and it is possible too that training in a trade, such as olog-making, may be provided for certain of the colonists. At Papworth, under the energetic management of Dr. Varrier Jones, there will be training in agricultural and gardening work, but carpentering and engineering shops are also being erected. In the latter a course of instruction will be given, having as its basis the agricultural motor trade, such motors being now much in request in the agricultural counties adjoining Papworth, and the work of driving such ploughs having been found suitable for the patients. The colony at Papworth bids fair, therefore, to develop into a training colony rather than a farm colony pure and simple.

Such variation is all to the good, and will help to show on what lines the movement may best attain permanent success.

The patients sent to the colonies by the Ministry will be carefully selected, and will be those with early disease, in whose sputum tubercle bacilli have been found, or who have had a definite attack of haemoptysis or pleurisy with effusion, thus leaving no doubt as to the correctness of the diagnosis. The patients will be received direct from the sanatorium, and must be capable of working at least six hours a day without pyrexia, malaise or undue acceleration of pulse. They will engage to stay a year at the colony. During their stay payments for maintenance and training will be made by the Ministry on behalf of patients whose cases have been accepted by the Ministry at rates agreed upon between the body responsible for the management of the colony and the Ministry. The individual patient will also be entitled to the following benefits: During the year of treatment and training the man's

pension will be in abeyance, but he will receive instead an allowance at the rate of 27s. 6d. per week, from which a certain amount will be deducted weekly towards the payment of his board and lodging. Out of the balance it is proposed to pay over to him 5s. weekly, leaving the remainder to accumulate for his benefit until he leaves the colony, or, should he desire it, the balance may be paid weekly to such dependants as he may name. In addition to the above allowance, the colonist will be entitled during the last six months of his course to a weekly bonus of 5s. per week, provided that he completes satisfactorily the full year's course of treatment and training. This bonus will be paid to him at the termination of his year's course.

At the Kinross Farm Colony it has been decided (and possibly similar arrangements may follow elsewhere) that at the end of the twelve months' course the colonist will also receive a small sum, representing half the net profits (as apportioned among the colonists) which it is hoped may accrue from the successful farming operations of the colonists, the exact amount depending largely upon their individual efforts. The remaining 50 per cent. will go towards defraying the cost of the maintenance of the colonists.

Such are the lines on which farm or training colonies are being developed in this country, and it is hoped that these institutions may be the means of giving a fresh start in life to many a deserving patient, who might otherwise drift downhill by returning to unsuitable work amid unsatisfactory surroundings. In association with the other measures already taken for the proper care and treatment of soldiers whose tuberculosis has been caused or aggravated by military service, they are also an earnest of the firm resolve of the Minister of Pensions to spare no pains and to save no effort in his determination to do all possible to help these most deserving men, who have jeopardized their health in the service of their country.

REMARKS ON ROENTGENOGRAPHIC PELVIMETRY.*

By W. R. MacKENZIE, L.R.C.S. Edin.,

ASSISTANT SURGEON TO THE SAMARITAN HOSPITAL FOR WOMEN, BELFAST.

In considering the use of the Roentgen rays in the diagnosis of pregnancy, and in the prognosis of difficult labour, attention is to be paid to the size and shape of the mother's pelvis and of the fetal head, and also the relation of the one to the other. This paper deals chiefly with the former, as in the majority of cases the abnormal presentation is due to pelvic deformity rather than fetal abnormality.

Since the existence of contracted pelvis was first reported by Arantius various methods have been employed for diagnosing the existence and measuring the extent of pelvic deformity.

External pelvimetry, introduced by Baudelocque, while enabling us to measure directly the external pelvic diameters, and thence to draw certain conclusions as to the degree of contraction, is insufficient for estimating the size of the pelvic cavity. This cannot be done directly in the living woman.

Internal Pelvimetry.—A method was devised by Skutsch which makes it possible to estimate the size of the pelvic cavity indirectly and with fair accuracy, but as the employment of his instrument is usually painful to the patient, an anaesthetic is required if an accurate diagnosis is to be made.

The Roentgen rays, it was thought possible, might afford a valuable method of investigating the size and shape of the pelvis, but it was found that, while an excellent idea as to shape was obtained, that as to size was erroneous,

owing to the fact that the sacrum and pubis lay at different levels from the sensitive plate, and consequently one portion of the pelvis was enlarged out of all proportion to the other. This defect made it impossible to utilize the radiograph for purposes of mensuration.

The employment of the following method will obviate this difficulty, and make it possible not only to see the existence and extent of the pelvic contraction both of the inlet and outlet, but also to compare it with the normal pelvis, and measure its degree without causing much inconvenience to the patient.

Method.

In a normal pelvic bone, which is designated the

"standard pelvis," the various diameters, both external and internal, are accurately measured. When this bone is radiographed definite points can be marked on the plate; the distance between these points will bear a definite ratio to that between the corresponding points measured on the

FIG. 1.—Drawing from skiagram of a normal pelvic bone, "standard pelvis."

FIG. 2.—Drawing from skiagram of abnormal pelvic bone.

pelvis. This radiograph is taken as the "standard plate." By radiographing the patient in the same position as the "standard pelvis," having the points of focus the same, the x-ray tube at the same angle and the same distance from the sensitive plate, an accurate comparison of the patient's plate with the "standard plate" will be obtained, and therefore of the patient's pelvis with the "standard" or normal pelvis; from it the internal measurements can be mathematically worked out: when compared to the direct measurements they are fairly accurate, as is shown by Figs. 1 and 2, there being an error of 2 mm. only. To work out mathematically the transverse diameter, for example, of the pelvic inlet the length of the transverse diameter of the pelvic radiograph of the patient is multiplied by the transverse diameter of the standard pelvis, and divided by the transverse diameter of

*Read before the Ulster Medical Society, March, 1913.

the standard plate. In the same way the antero-posterior diameter of the inlet or the transverse diameter of the outlet can be worked out. I have not mentioned the oblique diameters, because if the true conjugate is diminished the oblique will also necessarily be reduced in proportion.

Fetus.

It is possible to obtain the x-ray shadow of the fetus *in utero*, and this is a great clinical advantage in cases in which there is doubt as to the presence of pregnancy or the existence of abnormality. I am unable to state the earliest month at which the fetus can be recognized. It is necessary to take the x-ray plate in the earlier stages, if pelvic measurements are required, for in the later stages, as will be readily understood, the outlines of the pelvis may be more or less obliterated by the presenting part. An accurate comparison between the fetal skull and the pelvic inlet can be obtained if the photograph be taken when the head is about to engage in the pelvis.

While it is possible to measure the diameter of the head which lies parallel to the transverse diameter of the pelvis, it is not so with the diameter which enters the true conjugate. Therefore dependence must be placed on comparison rather than measurement. Even on finding the

Fig. 3, drawn from a skiagram, represents the pelvis of a healthy woman, aged 25 years, who has had three normal labours, and whose external measurements are normal. The internal measurements have worked out very satisfactorily when compared with the standard plate.

Fig. 5.—Drawing from skiagram—generally contracted pelvis.

relations of the fetal head to the mother's pelvis satisfactory, we must take into account the inability to judge the exact amount of mobility existing between the bones of the fetal skull, which, if soft, would mould themselves to the pelvis, but if densely ossified would be incapable of reduction in size.

Fig. 1 is a drawing from a skiagram of a normal pelvic bone, which is taken as the "standard plate"; the dimensions are :

	Pelvis: Direct Measurements.	Skiagram.
Inlet:		
Antero-posterior	11.5 cm.	13.5 cm.
Transverse	13.6 cm.	15.9 cm.
Outlet:		
Transverse	11.0 cm.	12.0 cm.

Fig. 2 shows an abnormal pelvic bone, the internal measurements of which show a very slight diminution when worked out by the above method as compared with the direct measurements, there being only an error of 3 mm. in the antero-posterior diameter of the inlet, 2.1 mm. in the transverse diameter of the inlet. It also shows clearly the diminution in the outlet.

	Pelvis.		Skiagram.
	Direct Measurement.	Worked Out.	
Inlet:			
Antero-posterior	10.5 cm.	10.2 cm.	12.0 cm.
Transverse	12.0 cm.	11.79 cm.	13.7 cm.
Outlet:			
Transverse	7.5 cm.	7.5 cm.	8.2 cm.

posterior is diminished over an inch. The transverse diameter of the outlet is 1 cm. larger than normal.

	Standard.		Mrs. "B."	
	Pelvis.	Skiagram.	Pelvis.	Skiagram.
Inlet:				
Antero-posterior	11.5 cm.	13.5 cm.	8.5 cm.	10.0 cm.
Transverse	13.6 cm.	15.9 cm.	13.6 cm.	16.0 cm.
Outlet:				
Transverse	11.0 cm.	12.0 cm.	12.19 cm.	13.3 cm.

Fig. 5 is drawn from a skiagram of a woman with a generally contracted pelvis. This patient's first confinement was terminated by craniotomy and the second by Caesarean section.

	Standard.		Mrs. "C."	
	Pelvis.	Skiagram.	Pelvis.	Skiagram.
Inlet:				
Antero-posterior	11.5 cm.	13.5 cm.	9.6 cm.	11.3 cm.
Transverse	13.6 cm.	15.9 cm.	11.71 cm.	13.7 cm.
Outlet:				
Transverse	11.0 cm.	12.0 cm.	10.8 cm.	11.8 cm.

Fig. 6 represents the pelvis of a healthy primipara seven and a half months pregnant. She consulted her own doctor as to his prognosis of a normal labour. He found on external pelvimetry that the distance between the anterior superior spines was only 8 in. and that between the iliac crests 9½ in. She was sent to me for x-ray pelvimetry.

External.—On comparing her x-ray plate with the "standard" there is considerable narrowing and apparent

flattening of the iliac bones, more marked on the right side. When worked out, the amount compares favourably with the doctor's direct measurements.

Between Iliac Crests.				Pelvis.	Skiagram.
Standard	28 cm.	32.5 cm.
Mrs. I.	23 cm.	26.8 cm.

At the level of the antero-inferior spines the bones are distinctly narrower than normal.

FIG. 6.—Drawing from skiagram—female pelvis showing deformity of iliac bones and normal cavity.

Internal.—On comparison with the "standard," the inlet appears normal, and when worked out it is as follows:

	Antero-posterior.		Transverse.	
	Pelvis.	Skiagram.	Pelvis.	Skiagram.
Standard ...	11.5 cm.	13.5 cm.	13.6 cm.	15.9 cm.
Mrs. I. ...	11.5 cm.	13.6 cm.	13.6 cm.	16.0 cm.

This case demonstrates clearly the advantages of this method of pelvimetry.

Fig. 7 is a case of normal full term pregnancy with a normal delivery, x-rayed at eight and a half months, and showing the fetal head engaging the pelvis.

FIG. 7.—Drawing from skiagram—fetal head engaging pelvis.

Conclusion.

In conclusion I would like to emphasize the following:

1. The necessity of a "standard" plate for pelvic measurements.
2. The patient must be radiographed in the same position as the "standard" pelvis, having the same point of focus, the x-ray tube at the same angle and at the same distance from the sensitive plate.
3. The accuracy of diagnosis in showing to advantage the variety of pelvic contraction, and the ease with which the various pelvic diameters can be worked out.
4. The minimum amount of discomfort to the patient compared to other methods of pelvimetry.
5. The absence of any ill effect to the fetus.

FROM October next the University of Maryland will admit women students to the medical department. Women have been admitted to the dental and pharmacy departments for some time.

THE PART PLAYED BY CONCOMITANT INFECTION WITH ANAEROBIC ORGANISMS (OTHER THAN *B. TETANI*) IN THE CAUSATION OF TETANUS.

BY

WILLIAM J. TULLOCH, CAPTAIN R.A.M.C.,

MEMBER WAR OFFICE COMMITTEE FOR THE STUDY OF TETANUS.

(From the Laboratories of the Lister Institute.)

I. INTRODUCTION.

THE problem of tetanus is bacteriological, and susceptible of solution only by bacteriological inquiry. While it is a platitude thus to state that the important factor in the causation of tetanus is reproduction of *B. tetani* in the living tissues or in immediate proximity thereto, it is almost necessary at the present time to emphasize this factor of infection as opposed to the factor of intoxication. The tendency on the part of investigators to focus all attention upon the process of intoxication and upon its mechanism has led to the disease being regarded from too limited a view point—that of the pharmacologist and physiologist.

The result has been that the prophylaxis of the disease has been so far limited to the employment of tetanus antitoxin, and to those general surgical measures designed for the limitation of sepsis. Admittedly tetanus antitoxin has reduced to a very remarkable extent the incidence of tetanus, but one feels that, as the immunity conferred by the prophylactic use of this agent is transient, lasting apparently only seven to ten days, and as even its repeated employment at seven-day intervals for a period of four weeks has not absolutely eliminated the disease, other influences in its causation, notably those relating to infection, are worthy of special attention.

The general surgical methods directed to the limitation of wound infection have also done much to assist this reduction in the numbers of cases of tetanus. It must be clearly appreciated, however, that even the most efficient antiseptic is unable to sterilize an infected wound, for the conditions obtaining in a wound, notably the presence of living tissue, are such that the value of any reagent which can be incorporated in a dressing is much reduced in respect of its bactericidal and antiseptic properties. So far, no substance has been obtained which does not exert a deleterious influence upon the tissues at the same time as it exerts a restraining influence upon the growth of bacteria in the wound exudate.

The ideal method of dealing with war wounds, which are all infected to a greater or less degree, is excision of the wound area. This, however, is not always practicable, and even when practicable a certain number of cases are bound to remain considerably infected—though the mass infection is greatly reduced—owing to the conditions under which military surgery must be practised in the field.

In what Direction can the Prophylaxis of Tetanus be Improved?

The experiments to be described indicate one direction in which improvement can confidently be hoped for and the measures which they suggest, while they in all probability will result in the limitation of the incidence of gas gangrene, will also form a valuable adjuvant to the prophylactic measures at present in use for the prevention of tetanus.

The reason for conducting the experiments under consideration is indicated in the results obtained by Vaillard and Vincent and by other investigators, who demonstrated that tetanus spores deprived of toxin by washing and heating, when injected into animals, do not frequently determine the development of the disease. If, however, an irritant foreign body were introduced, or a solution of an irritant chemical were injected along with such spores, tetanus almost invariably supervened. Similar experiments, in which growths of staphylococci or other aerobic micro-organisms were used as the irritant, gave variable results.

It may be stated broadly, then, that anything which causes devitalization of tissue will enhance the infectivity of *B. tetani*. The devitalizing factors that play a notable part in war wounds are (1) trauma and the presence of

foreign bodies in the tissues, (2) concomitant infection with other organisms.

The first of these is, when possible, dealt with by the surgical measure of excision of the wound area, which procedure also to a great extent limits infection with all organisms. But upon the nature of the concomitant infection may largely depend the subsequent development of tetanus. Anything which tends to bring about necrosis, and especially necrosis of muscle, will greatly enhance the development of the tetanus bacillus in wounds.

Is there any Known Infection Common in War Wounds that Leads Especially to Devitalization of Muscle?

While any infection by staphylococcus, streptococcus, or the colon bacillus, etc., may to some extent lead to this, there are two organisms which are particularly suspect—namely, *B. welchii* and *Vibrio septique*. As both of these develop diffusible toxins, and as the toxin of *B. welchii* is known—in consequence of the brilliant work of Major Carrol Bull, U.S.A.M.C.—to be definitely “myotropic,” it seemed of special value to determine the influence of the toxins of *B. welchii* upon the development of tetanus. An investigation of this kind is all the more imperative in that an antitoxin to *B. welchii* is available, while the prevalence of this organism in wounds, and its capacity for rapid growth, make it a peculiarly dangerous constituent of wound flora. It seems not improbable, too, that this suggested symbiotic relationship between *B. welchii* and *B. tetani* may play some part in the causation of cases of delayed tetanus. It is conceivable that when wounds have healed and a slight trauma, received later, has resulted in the development of acute tetanus, there has been a reproduction of *B. welchii* or *Vibrio septique* locally which has exerted a trigger effect in the development of resting tetanus spores lying in the wound area. In such instances it is improbable, unless the trauma be fairly severe, that *B. tetani* develops without some assistance of the kind indicated. In an animal susceptible to tetanus the degree of infection by *B. welchii* required to light up tetanus need not be marked, so that it may well escape clinical observation.

Could we combat the necrotizing influence of *B. welchii*, and of other similar organisms, during the early stages of wound treatment much might be done to assist in the healing process, and, what is equally important, a healthier scar with fewer necrotic islets within it would be obtained. In order to investigate the symbiotic relationship suggested in the preceding paragraph the following experiments were undertaken.

II. EXAMINATION OF THE INFLUENCE OF THE TOXIN OF *B. WELCHII* UPON THE DEVELOPMENT OF TETANUS SPORES IN VIVO.

Reagents Employed.

In all series of the experiments the tetanus spores were prepared thus:

Tubes of Douglas broth, enriched by the addition of fresh sterile rabbit kidney and incubated to ensure sterility, were inoculated each with one of the definitive serological strains of *B. tetani*. The tubes were incubated for three weeks at 37° C., by which time the maximum sporulation had taken place. The growths were then filtered through sterile wool, centrifuged, and the supernatant fluid pipetted off. The deposit was suspended in saline and the tubes again centrifuged. This process having been repeated twice, sufficient saline was added to make the spore content of each suspension equal to 2,000 million spores per cubic centimetre, and the suspension was then heated to 80° C. for thirty minutes.

The toxin of *B. welchii* employed was of such potency that it caused the death of one guinea-pig of 250 grams weight out of three that were inoculated, when administered intramuscularly in a dose of 1 c.cm.; and only produced slight oedema when injected by the same route in a dose of 0.2 c.cm. diluted in 1 c.cm. of saline.

The antitoxin of *B. welchii* used was the product of the Rockefeller Institute of Experimental Medicine, and was marked as “Horse 2,” and contained 1,400 units of antitoxin per cubic centimetre.

A preliminary series of experiments was carried out (1) to determine approximately how many washed and heated tetanus spores could be injected into the guinea-pig without causing the development of tetanus, and (2) to determine what dosage of the toxin of *B. welchii* available invariably produced the disease (tetanus) when injected along with a constant number of tetanus spores, but was

by itself unable to cause more than slight oedema, demonstrable by palpation.

These preliminary experiments showed that if care were taken 1,000 million washed and heated spores could be injected in a volume of 1 c.cm. into the gastrocnemius of the guinea-pig without causing tetanus. It was therefore decided to employ this number of spores in all subsequent experiments, as such a number excluded the possibility of any inoculum consisting entirely of non-viable spores.

When this number of spores was injected along with 0.2 c.cm. of the toxin of *B. welchii*, the whole inoculum having a volume of 1 c.cm., acute tetanus invariably developed on the second or third day after inoculation. This experiment was carried out using three series of three animals each.

1. Animals *a*, *b*, and *c* were injected with 1,000 million Type 1 tetanus spores plus 0.2 c.cm. of *B. welchii* toxin, the volume of the inoculum being 1 c.cm. and the inoculation made into the right gastrocnemius.

2. Animals *d*, *e*, and *f* received the same inoculation, but Type 2 spores were used instead of Type 1 spores.

3. Animals *g*, *h*, and *i* received the same material, but Type 3 spores were used in this instance.

All nine animals died of acute tetanus between the second and third days after inoculation. Control experiments, in which 1 c.cm. of normal horse serum was inoculated into the left gastrocnemius before the inoculation was made on the right side, showed that normal horse serum did not prevent the fatal issue.

When a smaller dose of the toxin of *B. welchii*—less than 0.2 c.cm.—was employed, especially if it were diluted, the results were variable. It was therefore decided to employ in future experiments 0.2 c.cm. of the toxin. Having thus obtained an experimental method which gave constant results, I proceeded to determine whether passive immunization with *B. welchii* antitoxin would prevent the development of tetanus in animals inoculated with mixtures of tetanus spores and *B. welchii* toxin. The following series of experiments was therefore carried out. Details are given of the experimental methods employed in each series.

Experiment I.

Guinea-pig I was inoculated in the right gastrocnemius with 1,000 million spores Type 1 (U.S.A.) tetanus in 1 c.cm. saline. For the first five days the animal was well; on the sixth and seventh days it limped slightly (? local tetanus); on the eighth day there was no obvious limp, and on the remaining six days during which the animal was under observation it remained well.

Guinea-pig II was inoculated with 1,000 million spores Type 1 tetanus plus 0.2 c.cm. *B. welchii* toxin (volume 1 c.cm.). The following day there were signs of local tetanus; on the second day there was definite local tetanus; and on the third day the animal died.

Guinea-pig III also received 1,000 million spores Type 1, plus 0.2 c.cm. *B. welchii* toxin (volume 1 c.cm.), in the right gastrocnemius. One hour later 1,400 units of *B. welchii* antitoxin were injected into the left gastrocnemius. The animal showed no sign of tetanus, and remained well during the period it was under observation.

Experiment II.

Guinea-pig I A was inoculated in the right gastrocnemius with 1,000 million Type 2 tetanus spores in 1 c.cm. saline. It remained well for the first five days; on the sixth there was a slight limp (? local tetanus); on the seventh day there was definite local tetanus; on the eighth general tetanus, and the animal was killed.

Guinea-pig II A was inoculated with 1,000 million Type 2 tetanus spores, plus 0.2 c.cm. *B. welchii* toxin (volume 1 c.cm.). On the first day the animal appeared to be well; on the second it was moribund, and was killed.

Guinea-pig III A received 1,000 million Type 2 tetanus spores, plus 0.2 c.cm. *B. welchii* toxin (volume 1 c.cm.), in the right gastrocnemius. Two hours later 1,400 units of *B. welchii* antitoxin were injected into the left gastrocnemius. For the first five days the animal was well; on the sixth and seventh days it limped slightly (? local tetanus); on the eighth day the limp was less marked, and on the ninth day the animal was well, and remained well during the time it was under observation.

Experiment III.

Guinea-pig I B was inoculated with 1,000 million Type 3 tetanus spores in 1 c.cm. saline, in the right gastrocnemius. Guinea-pig II B received 1,000 million spores Type 3, plus 0.2 c.cm. *B. welchii* toxin (volume 1 c.cm.). Guinea-pig III B was inoculated in the right gastrocnemius with 1,000 million spores Type 3 plus 0.2 c.cm. *B. welchii* toxin (volume 1 c.cm.), and received 1,400 units *B. welchii* antitoxin in the left gastrocnemius. Guinea-pig I B remained well; Guinea-pig II B died of tetanus on the third day; and Guinea-pig III B, beyond exhibiting slight stiffness of the inoculated limb from the sixth to the fourteenth day after inoculation, remained well.

The deductions to be drawn from these three experiments are self-evident. They indicate that an antitoxin for *B. welchii* and tetanus antitoxin should be employed together for the routine serum prophylaxis of tetanus. The evidence is unequivocal that the antitoxin of *B. welchii*, in addition to neutralizing its toxin, has the advantage that it completely protects (in the case of the guinea-pig) against the development of tetanus spores in tissue which has been exposed to the devitalizing effect of that toxin. It is highly probable that the same protecting value would be found in the case of man.

Attention is called to the death of the control animal, I A, in Experiment II. The death of this animal, while in no way detracting from the validity of the experiments or of the deductions to be drawn from them, indicates that the development of tetanus depends upon a number of different factors. It is not improbable that in this instance a certain degree of trauma, when the inoculation was made, was responsible for the development of the infection. It is to be specially noted, however, that while the test animal, II A, died on the second day after inoculation, the control animal did not die until the eighth day. Moreover the test animal died of acute, almost fulminating, tetanus, while the course of the disease in the control animal was much less acute. Experiment II is therefore exceptionally instructive, for, while it shows that the danger of infection with *B. tetani* and notably of early development of the disease owing to symbiosis with *B. welchii* could be considerably mitigated, if not completely eliminated, by the use of a combined serum for prophylaxis, it also calls attention to the fact that while such a reagent would probably be of great value, surgical measures could not be permitted to be less carefully applied because of its introduction.

I call attention to this as, if a combined prophylactic serum were to be introduced, it might lead to the development of a feeling of false security, and too optimistic a view might be taken regarding the probable value of such a combined serum. As a natural sequence its unmerited condemnation would ensue if the results obtained did not completely bear out expectations.

III. INFLUENCE OF THE TOXIN OF *VIBRION SEPTIQUE* ON THE DEVELOPMENT OF TETANUS SPORES IN VIVO.

Vibrio septique is another of the organisms which are commonly found in wounds, and develop diffusible toxic products. While it is not known whether the toxin of this organism is a particularly active necrotizing substance or only has marked oedema-producing properties, it seemed of importance nevertheless to determine the possible influence which it might exert upon the development of tetanus.

As the properties of this toxin, then, are at present less well defined than are those of the toxin of *B. welchii*, the experiments to be described in this section cannot be so clearly interpreted as are those dealt with in section II of the present communication. This difficulty is enhanced by the fact that at the time of writing specific *Vibrio septique* antitoxic serum was not available, so that protection experiments could not be undertaken.

I here wish to record my thanks to Miss Robertson of the Lister Institute of Preventive Medicine for placing at my disposal a quantity of the toxin of *Vibrio septique*.

The methods employed and the results obtained in making this investigation were as follows:

Experiment IV.

Guinea-pig A was inoculated in the right gastrocnemius with 0.25 c.cm. *Vibrio septique* toxin plus 0.75 c.cm. saline. On the first day there was slight oedema and stiffness of leg. On the second day the oedema was palpable, but not extensive; there was still stiffness of leg. On the third day the oedema was almost gone and the leg less stiff. On the fourth day the animal had almost recovered, and on the fifth day it was well, and remained so during the period of the experiment.

Guinea-pig B was inoculated with 0.25 c.cm. *Vibrio septique* toxin, plus 0.25 c.cm. saline, plus 1,000 million tetanus spores. Type 1. On the first day there was slight oedema and stiffness of leg. On the second day oedema palpable but not extensive; still stiffness of leg. On the third day the animal was recovering, and on the fourth it had almost recovered. On the fifth day it was well, and remained so.

Although the oedema resulting from the injection of 0.25 c.cm. of this toxin was quite as marked as, if not more marked than, that produced by 0.2 c.cm. of the toxin of *B. welchii*, it is remarkable that tetanus did not

develop. I therefore decided to make the test much more stringent, employing 1 c.cm. of the toxin plus 1,000 million tetanus spores. The result of an experiment employing this technique is shown below.

Experiment V.

Animal C was inoculated in the right gastrocnemius with 1 c.cm. *Vibrio septique* toxin plus 0.5 c.cm. saline. On the first day there was marked oedema over the whole of the injected limb; on the second the oedema was more marked and extending over the abdominal wall, soft on palpation. The next day the oedema was reduced and the animal lively; limb stiff. On the fourth day the oedema was disappearing; leg still stiff. On the fifth day the animal had recovered, and remained well till the conclusion of the experiment.

Animal D received 1 c.cm. *Vibrio septique* toxin, plus 1,000 million Type 1 tetanus spores. On the first day there was marked oedema over the whole of the injected limb; on the second, oedema as in animal C. On the third day the oedema was reduced and the animal lively, but limb stiff. Fourth day, oedema almost gone; leg still stiff. On the fifth day the animal was well, and remained so.

A slight stiffness of the limb remained in both animals until the completion of the experiment, which was considered to have occurred on the fourteenth day. The animals have remained well, and the stiffness is slowly disappearing. This experiment is striking in that although the oedema produced in the animals was much more marked than that resulting from the injection of 0.2 c.cm. of the toxin of *B. welchii* employed in the previous series of experiments, no development of tetanus occurred.

This result was scarcely expected, and the experiment was therefore repeated.

Experiment VI.

Animal E was inoculated with 1,000 million Type 1 tetanus spores suspended in 1.5 c.cm. of saline. Animal F with 1 c.cm. of *Vibrio septique* toxin plus 1,000 million Type 1 tetanus spores. These animals both remained well, so corroborating the findings indicated in Experiment V.

As the disturbance produced by *Vibrio septique* toxin—oedema production—was so pronounced, it seemed remarkable that tetanus did not develop. The experiment was repeated a second time, using spores of a representative Type 3 tetanus bacillus. The findings of this experiment are as follows:

Experiment VII.

Animal G was inoculated in the right gastrocnemius with 1,000 million Type 3 tetanus spores suspended in 1.5 c.cm. saline. It remained well. Animal H was inoculated with 1,000 million Type 3 tetanus spores plus 1 c.cm. *Vibrio septique* (volume 1.5 c.cm.). There was marked oedema on the first day, but the animal was active. On the second day there was general tetanus, and the animal was killed.

As specific antitoxin for *Vibrio septique* was not available it was decided not to complete the present series of experiments using Type 2 spores, for the results shown in Experiment VII indicate that *Vibrio septique* may, like *B. welchii*, play an ancillary part in the causation of tetanus.

The negative results obtained on three occasions when Type 1 spores were used indicate, however, that the toxin of *Vibrio septique* is probably a less constant factor in stimulating the growth of *B. tetani* in the tissues than that of *B. welchii*. In view, however, of its frequent occurrence and in view of the fact that it sporulates more readily than does *B. welchii*, its capacity for doing harm is possibly extended over a more prolonged period than is the case with *B. welchii*. It would seem, therefore, advisable that antibodies to the toxin of *Vibrio septique* should also be included in serum used for the prophylaxis of tetanus.

Commenting on the results obtained in the two series of experiments described in the present communication, it is to be noted that Vaillard and Vincent foreshadowed the possibility of its being demonstrated that certain organisms might play a more important part in stimulating the growth of *B. tetani* *in vivo* than would others.¹

CONCLUSIONS.

1. There is good ground for believing that the ancillary part played by *B. welchii* in the causation of tetanus is clearly defined. The capacity of this organism for doing harm in the connexion under consideration can be almost eliminated by the use of the antitoxin for *B. welchii*.

2. The capacity shown by the toxin of *Vibrio septique* for stimulating the growth of tetanus spores *in vivo* is more

variable than is that of *B. welchii*. Experiment VII indicates, however, that it too may play a part in the causation of tetanus.

3. It follows from conclusions 1 and 2 that antibodies to the toxins of *B. tetani*, *B. welchii*, and *Vibrio septique* should be included in all serum employed for the prophylaxis of tetanus.

4. While such a polyvalent serum promises to reduce still further the incidence of tetanus it would be too optimistic to assume that it would absolutely eliminate that disease, for infections other than those dealt with in this communication may also play a part in stimulating the growth of *B. tetani* in wounds. One of these, *B. oedematis*, I propose to investigate immediately.

ANEURYSM OF THE THIRD PART OF THE LEFT SUBCLAVIAN ARTERY,

SUCCESSFULLY TREATED BY LIGATURE OF
THE SECOND PART.

By HERBERT H. BROWN, M.D., F.R.C.S.,

SURGEON TO THE EAST SUFFOLK HOSPITAL, IPSWICH.

IDIOPATHIC aneurysm of the subclavian artery is not common, and until recent years its treatment has been most unsatisfactory. Ligature of the first part of the artery is an operation of considerable difficulty, owing to the anatomical relations of the vessel and its depth from the surface, and in pre-antiseptic times was invariably fatal.

The second part, behind the scalenus anticus, has apparently not often been chosen for ligature; but it is far more accessible than the first part, and the operation is not especially difficult. In the case recorded below, I started the operation with the idea of ligaturing the first part, but found the second part could be more easily reached, and there was no difficulty in ligaturing the vessel. The result of the operation was completely satisfactory.

The patient, a farm labourer aged 50, was admitted into the East Suffolk Hospital on February 27th, 1918, complaining of severe pain in the left arm, which kept him awake at night. There was a pulsating oval tumour extending above the clavicle into the posterior triangle, rather smaller than a hen's egg. The left radial pulse was distinctly smaller than the right. The systolic pressure in the right brachial artery was 230 mm., in the left 195. The patient was kept in bed, given potassium iodide, and morphine at night.

Operation.

On March 8th, 1918, an incision was made along the posterior border of the sterno-mastoid, commencing at about its centre, and extending over the head of the clavicle for an equal distance on to the thorax; it was about six inches in length or rather less. The posterior edge of the sterno-mastoid was defined, the muscle drawn inwards, glands, etc., removed, and the internal jugular vein exposed. The attachments of the sterno-mastoid to the upper border of the clavicle, and of the pectoralis major to the lower border, were divided, and the inner half of the bone cleared with a periosteal elevator, the clavicle was divided with a saw, disarticulated at the sterno-clavicular attachment, and the inner half removed. The subclavius muscle was taken away and a large suprascapular vein; the subclavian vein was then exposed and cleaned. After removal of some lymphatic glands the scalenus anticus with the phrenic nerve was defined. It was evident that the aneurysm commenced at the outer edge of the scalenus anticus, and was confined to the third part of the artery. The first part had not yet come into view. The phrenic nerve was drawn inwards, the vagus, internal jugular, and internal carotid were also retracted out of the way, and the scalenus anticus muscle divided a short distance above its attachment to the rib.

The second part of the subclavian artery was now fully exposed to view. It appeared to be quite healthy and normal, and there was no difficulty in passing a ligature round it. Two silk ligatures of No. 4 silk were tied sufficiently tightly to occlude the vessel without rupturing the coats. Pulsation in the aneurysm and radial artery

immediately ceased. The wound was closed after suturing the divided sterno-mastoid and pectoral muscles, and a small drainage tube left in the centre of the wound. This was removed after forty-eight hours.

The patient made an uninterrupted recovery. The left arm and hand continued to be quite warm and free from pain. There was never any cyanosis or oedema. Muscular movements and sensation were unaffected. He left the hospital on March 28th, within three weeks of the date of operation.

I saw the patient again a month later—April 28th. He looked and felt perfectly well. All movements of head and arm were normal. He was quite free from pain and was advised to return to work. The radial pulse was still absent; the only trace of the aneurysm was a very small soft tumour above the clavicle resembling a lipoma. The systolic pressure in the right brachial artery was then 165 mm.

The operation has apparently been completely successful.

I am indebted to Colonel A. Carless for his kindness in giving suggestions as to the line of incision and *modus operandi*, and to my colleague, Mr. A. Y. Pringle, and Mr. Arthur Woo, the house-surgeon, for assistance during the operation.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF CEREBRAL TOXAEMIA— ?"BOTULISM."

THE following notes relate to a patient recently under my care. In the light of the interest lately aroused in the subject of botulism, and in consideration of the "epidemic" character of that disease, a report of this case, which occurred in Glasgow, may be suggestive epidemiologically. So far as I am aware, no case has, at this time, been recorded further north than Leeds.

Clinical Features.

J. G., male, aged 35, was admitted on May 6th, notified as typhus. His illness began on May 1st. The history, given by the relatives, was unsatisfactory, but headache, sickness, constipation, stupor, and delirium were the prominent features. The latter two appeared early, persisted throughout, and, as the disease progressed, tended to deepen.

On admission: coma, pyrexia (101–103° F.), sordamina or toxic erythema, dry brown flaccid tongue, bucco-pharyngeal hyposecretion, dysphagia, palatal paralysis, divergent strabismus, slightly dilated pupils reacting sluggishly to light, and retention of urine. Cerebral excitement was a prominent feature, producing muscular tremors greatly aggravated by interference. Forcible raising of the arms or separation of the legs revealed a spastic tone of the musculature. Movements constant, irregular, quick, choreoid (as in choreic diplegia), involuntary—although sufficiently purposive to necessitate restraint of the arms to prevent interference with catheterization. Sensation appeared hyperacute, as even slight digital pressure induced exaggerated collateral muscular response. Knee-jerks exaggerated, Kernig and Babinski present, ankle clonus indefinite. Heart: rate 120–144, sounds indefinite. Lungs: bronchopneumonic catarrh. Trace of albumin in urine. Abdominal examination negative.

Although, clinically, the case in no way resembled typhoid fever, the Widal reaction showed complete agglutination of *B. typhosus* in a dilution of 1 in 50 in an hour and a half.

Whereas, on admission, there appeared to be photophobia, next day paresis of both levatores palpebrae superioris was evident, and on the day before death there was bilateral ptosis with slightly contracted, fixed pupils. Bilateral facial paralysis was suspected, but could not be established on account of the profound stupor. Percussion over the chin and attempts at drinking produced a curious clonus of the masticatory muscles. The electrical reactions were not examined. Sixty hours after admission death occurred peacefully as from a gradual paralysis of the respiratory centre.

Post-mortem Findings.

Skin.—Over the shoulders, upper arms, and sides of thorax there were numerous small, circular, brownish spots, of variable size, some showing minute vesicular elevation. Over both suprascapular regions and backwards over the shoulders there was a copious eruption of sudamina.

Chest.—The left lung was intensely hyperaemic and oedematous. The right lung had an ill-defined area of pneumonic consolidation in the lower lobe posteriorly, the upper part of the lobe and the upper lobes being hyperaemic and oedematous.

Heart.—The wall of the left ventricle showed cloudy swelling, and the cavity was dilated; valvular structures normal.

Abdomen.—Spleen enlarged, very hyperaemic, but fairly firm; kidneys hyperaemic; liver not enlarged, but on section some biliary staining and cloudy swelling. All over the cardiac end of the stomach the mucous membrane was hyperaemic, but

there was no ulceration. The pancreas appeared normal. The mucous membrane of the small intestine was deeply bile-stained throughout. Just below the caput caecum the mucous membrane was hyperaemic and haemorrhagic for 12 inches.

Brain.—The pia arachnoid over the parieto-occipital regions showed a large accumulation in the deeper sulci of a slightly opaque greyish fluid. The larger vessels of the meninges and throughout the brain substance were enlarged, and the tissue, both grey and white, was pinkish from hyperaemia. The spinal cord showed similar hyperaemia of its surface and substance.

A routine bacteriological, serological, histological, and physiological investigation is being undertaken, but the results are at present incomplete.

Although careful inquiry was made of the relatives, no evidence was forthcoming that the condition had a "food origin." Noteworthy features of the case were the sudden onset, the early appearance of stupor and extreme prostration, the multiplicity of signs pointing to central nervous system toxæmia, and the comparatively negative findings at section.

I am indebted to Dr. Archibald, medical superintendent, for permission to publish this case, and my best thanks are due to Dr. Buchanan, city bacteriologist, for the use of his notes made at the post-mortem examination.

JAMES LAW BROWNIE, M.B.,

Hospital, Glasgow.

Reports of Societies.

INDUSTRIAL TUBERCULOSIS.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 24th, the President, Dr. G. S. BUCHANAN, in the chair, Dr. E. L. COLLIS (Director, Welfare and Health Section, Ministry of Munitions) opened a discussion on the incidence of industrial tuberculosis. Dr. Collis remarked that the etiological factors more or less intimately associated with industrial environment were: (1) Overcrowding, the aggregation in sufficiently close proximity to allow of spray infection by coughing amongst persons not inherently subject to an excessive incidence of tuberculosis; (2) the presence in an otherwise normal environment of an unusual number of cases of tuberculosis; (3) alcoholism, associated with industrial employment as "industrial drinking," whether by custom of the trade, or owing to conditions of heat or dust; (4) illness—that is, a lowered general resistance dependent upon long hours, imperfect ventilation, bad feeding, lack of rest and healthy recreation; (5) inhalation of injurious dust, which might be summarized as exposure to the inhalation of silica dust. Shoemakers illustrated the class where, save for the possibility of infection, no adverse influences, such as fatigue, low wages and malnutrition, alcoholism, bad housing, bad ventilation, or imperfect lighting, were more intense than in industries not suffering unduly from tuberculosis. A similar remark was applicable to the printing trades. The case of publicans and inn servants might typify the peculiar influence of alcohol as lowering the general bodily resistance, mortality being excessive for all causes. Tin miners showed the features of a group where a specific predisposing cause in the shape of exposure to silica dust was the important factor. The importance of contrasting these groups lay in the consideration that when it was desired to unmask the causes of an undue prevalence of tuberculosis it was necessary to know whether such prevalence were or were not associated with an unduly high mortality from other diseases. Were such an association found, then attention might be directed to some other influence which affected the issue; in the absence of such association, as in the case of shoemakers, the field of inquiry was narrowed. It was of interest to remark that the curve of age-incidence upon shoemakers was similar in form to that describing the experience of all occupied and retired males; the similarity being sufficiently striking to suggest that the influence at work, although more intense, was not different in kind from that responsible for tuberculosis incidence as a whole. On the other hand, the curves for publicans and tin miners were quite different both from the standard and from one another, suggesting a different

etiology, which, on other grounds, was usually admitted to be the case. Owing to the great difficulty, amounting in many cases to impossibility, of securing industrial incidence rates, it was advisable to utilize the method of proportional mortality, that is, to study the proportion of recorded deaths attributable to tuberculosis. It appeared to be a rule admitting but few exceptions that when the proportional mortality was high the absolute incidence was also excessive, and he (Dr. Collis) was disposed to agree with Hoffman's conclusion that this method, although admittedly imperfect, could render valuable service in the investigation of industrial diseases. An important caution should be given in connexion with the study of mortality records—namely, that, owing to change of occupation, mortality returns were not altogether trustworthy indices of industrial morbidity. In this connexion the classical investigation of Finlaison in 1853 and the more recent work of Watson merited special notice. No complete study of industrial morbidity had been undertaken in this country, and such a task would appear to await the advent of a Ministry of Health.

Captain M. GREENWOOD (Welfare and Health Section, Ministry of Munitions) desired to direct attention to two points. In the first place, the death-rate from tuberculosis among women had shown a slight but real increase since the outbreak of war, amounting to about 6 per cent. between 1914 and 1916. Dr. Stevenson had suggested that this increase might be attributable to the employment of women in industry, and had drawn attention to the fact that women over 45 did not participate in the change. He (Captain Greenwood) found that an application of the tuberculosis rates observed among employed women at Leipzig, and published by the German Imperial Statistical Department in 1910, to the English female population as distributed in industries before the war and again in 1916 (according to the Board of Trade's estimates) gave approximations very close to the observed facts; hence it seemed very probable that the industrial redistribution produced by the war was really the explanation of the change. In the second place, he suggested that the explanation of differential incidence of tuberculosis by an appeal to selection—namely, the argument that it was not so much the occupation as the type of recruit entering the occupation which determined the incidence—was insufficient to account for the phenomena. If a prediction of the phthisis rate at ages 35–45 in industrial occupations (excluding the silica groups and, of course, non-industrial and professional classes) were founded upon the death-rate from all other causes at the same age, and also upon the death-rate at ages 25–35 in the same occupations as observed in the previous decennium, it appeared that certain groups—namely, bookbinders, printers, shoemakers, tailors, and cabinet-makers—exhibited an exceptionally heavy phthisis mortality, not to be accounted for either by their death-rate from other causes or their mortality at earlier ages (so far as this could be measured by the previous decennial records). Although the method was open to some criticism, its application appeared to support the opinion that in the occupations named a special and peculiar tuberculosis problem needed solution.

Dr. BENJAMIN MOORE, F.R.S. (Medical Research Committee), questioned whether Dr. Collis had put sufficient emphasis upon the factor of low nutrition. The majority of occupations experiencing a very heavy incidence of tuberculosis were characterized by the stigmata of intermittent and badly paid labour. Apart from these, he thought it was possible to classify occupations, bringing into relation the nature of the product handled and the incidence of tuberculosis. He also desired to emphasize the necessity of close study of the actual factory conditions.

Dr. JOHN BROWNLEE (Medical Research Committee) did not consider that the problem of tin miners' phthisis was entirely explicable on the lines followed by Dr. Collis. Attention must also be directed to the general epidemiology of the disease. Tin mining was a localized industry, and the curve of incidence upon all inhabitants of the district was *sui generis*. He had studied the age incidence of phthisis as portrayed in the regional reports of the Registrar-General, and the result emerged that, epidemiologically, phthisis was not one disease, but certainly two and perhaps three diseases, each characterized by a special age incidence. The student of industrial phthisis would have to take into consideration these epidemiological aspects of the subject.

PHYSIOLOGY OF CHLOROFORM ANAESTHESIA.

A MEETING of the Section of Anaesthetics of the Royal Society of Medicine was held on May 7th, with Dr. J. BLUMFIELD, Vice-President, in the chair. After sympathetic reference had been made to the recent lamented death of the President, Mr. George Rowell, Dr. G. A. BUCKMASTER read a paper entitled "Some considerations on the physiology of anaesthesia by chloroform." Experiments were described that had been carried out with Dr. J. A. Gardner for ascertaining anaesthetic and lethal quantities of chloroform in the blood of animals narcotized and killed, the part played by the red corpuscles in the transport of the drug, and the rates of assumption and elimination of chloroform. It was found that as much as 94 per cent. of the drug may be carried by the red corpuscles, in the cell proteins of which it is probably absorbed. In experimental anaesthetization with known percentages of chloroform a primary and secondary danger point were recognized. When the first is passed the average chloroform content of arterial blood is about 27 mg. per 1,000 grams of blood at disappearance of reflexes in the case of cats and 31 mg. in the case of dogs. During anaesthesia the quantity slowly and steadily increases. Respiration ceases in cats with about 40 mg. and in dogs with 61 to 69 mg. The body weight, without fat, appears to be without influence on the percentage of chloroform in the blood necessary to produce anaesthesia. It is the percentage value of chloroform in the blood that is important, for this remained constant during complete anaesthesia in animals with (1) normal quantity of blood, (2) diminution through haemorrhage, (3) augmentation through transfusion, though the total quantity of chloroform rose and fell with the corpuscular richness and poverty of the blood. This percentage value must stand in relation to the solution pressure in virtue of which the drug enters the cells of the organism. A chart was shown illustrating the rate of assumption of chloroform by the blood during anaesthesia and the rate of elimination afterwards. Chloroform is neither decomposed nor oxidized within the body. It was shown that in the work of Nicloux the carbon monoxide actually found was produced during the analysis of the blood gases. The blood yields carbon monoxide during blood-gas analysis over potash. Ventilation of the lung during chloroform narcosis can be ascertained only by plethysmographic methods with an apparatus similar to that used by Haldane and Boycott. During the first three minutes the lung ventilation is diminished by 50 to 60 per cent. of its original value. From this some recovery occurs, but prolonged anaesthesia always diminishes the lung ventilation by a similar amount, 60 per cent. of the original value. Tables were shown giving comparisons of the total blood gases under chloroform and ether. The former drug markedly affects the gas content of the blood, the latter scarcely at all. The diminution in oxygen content of the blood in chloroform narcosis is not due to the diminished lung ventilation, but probably to the direct action of the drug on the red corpuscles. During complete anaesthesia the fall in oxygen is 40 per cent. The haemoglobin is therefore only partially saturated with oxygen during chloroform narcosis. The haemoglobin is, in fact, in the same state of partial saturation with oxygen that it would be with an oxygen tension to the alveolar air of only 45.5 mm. Hg, whereas the normal tension is 99.49. A discussion followed, in which Dr. A. G. LEVY, Professor A. D. WALLER, Mr. P. L. MUMFERY and others took part. Dr. O. MILLAURO demonstrated an improved foot key with rubber surface for use with gas cylinders, and Captains C. HENSEH and H. E. G. BOYLE showed apparatus for continuous administration of gas and oxygen and ether.

OVARIAN GRAFTING.

At a meeting of the North of England Obstetrical and Gynaecological Society, held at the Medical Institution, Liverpool, on May 10th, with Professor BRIGGS, Vice-President, in the chair, Mr. BLAIR BELL read a paper on the technique and value of ovarian grafting in the human subject. He insisted that grafts must be autophagic, small in size, and from the interior—follicles, as he pointed out, being unessential for the conservation of the uterine function. The operation was not indicated in women over 42, in women sexually inactive, or in cases

where conservation was at all possible. Grafts were stored in the utero-vesical pouch until the later stages of the operation, and were then embedded either in the abdominal wound, the drainage wound, or in the fundus of the uterus, according to the variety of case operated on. After-histories in a series of 20 cases were noted as regards (1) absence of menopausal symptoms, (2) persistence of menstruation, and (3) general health. The paper was discussed by Drs. DONALD, WALLS, BRIGGS, GEMMELL, and SUMNER. Dr. WALLS exhibited a specimen of fibroid of uterus undergoing cystic degeneration; Dr. BRIGGS a large ovarian fibroma, 11½ lb. in weight, with no degeneration; and Mr. BLAIR BELL a specimen showing red degeneration in a fibromyoma uteri sixteen years after the last pregnancy, associated with pyosalpinx; and a large myoma uteri of unusual appearance and with few symptoms in a young woman aged 25. Dr. CLIFFORD read notes on a case of ascites in successive pregnancies with albuminuria. Dr. BRIGGS described a case of acute abdomen during pregnancy, due to twisting of the pedicle of a small ovarian fibroma with small fibroma of the abdominal wall; and Dr. HENDRY a case of missed abortion carried two months over the full term.

Reviews.

ADAPTATION AND DISEASE.

ALL pathologists will welcome, as should also all biologists, the appearance of Professor ADAMI's Croonian Lectures on adaptation and disease in a volume in which are reprinted a number of earlier articles dealing with questions bearing on the theory of evolution.¹ Even if we may not always be in agreement with the learned author, he gives us much to think about and opportunity to clarify our minds. In the small space available here it is clearly impossible to do more than refer to the two main theses of the book, and, if difficulties are pointed out, they will, it is to be hoped, have the effect of sending readers to the book itself. A mere list of its contents would serve no good purpose.

One of these theses is that it is not true to say that no acquired conditions can be inherited. Few, if any, physiologists would be inclined to dispute this. Whether or not the germ plasma is susceptible to nervous action on the part of the organism that harbours it, it is impossible to believe that it is free from the influence of chemical factors contained in the liquid that surrounds it. Stockard's experiments on the degenerative changes produced by alcohol in guinea-pigs, effects still present several generations after exposure of the original animals to the vapour of alcohol, are given in detail in the book before us, and are conclusive. On the other hand, from this point of view it is not to be expected that mutilations of tissues which leave untouched other similar masses would have any effect on the germ plasma. I do not know whether Guthrie's work on the transplantation of ovaries in black and white fowls has been confirmed; but it also indicates an influence of the soma of the black variety on the germ plasma of the white variety, when transplanted into the former.

The other thesis—namely, that there is such a thing as direct adaptation—is likely to lead to more opposition. The question is one of great importance and the evidence must be carefully considered. I am bound to confess that the array of evidence brought by the author has failed to convince me. It may be due to failure to appreciate the complete meaning of the facts or to the influence of preconceived ideas; but I find it impossible to imagine how the incidence of a new force on an organism is more likely to result in a reaction which is favourable to that organism than the reverse. Whatever the reaction may be, it must be the result of the nature and properties of the reacting mechanism, and it may or may not be an appropriate one. If the former, it might perhaps be claimed as a direct adaptation; but surely the use of the word "adaptation" is misleading. Considerations of this kind have been put forward by Professor Parker of Harvard in the *American Naturalist*; vol. xlvii.

When we examine the evidence for direct adaptation, we find that it is of two kinds—either the development of new

¹ *Medical Contributions to the Theory of Evolution*. By J. G. ADAMI, M.D., F.R.S., F.R.C.P. London: Duckworth and Co. 1918. (Pp. 372; 7 plates, 20 figures. 18s.)

powers in successive generations of bacteria when exposed to new conditions, or the phenomena of immunity in the higher animals. In the former case, it seems difficult to exclude satisfactorily the intervention of favourable variations. We know that, in the absence of their favourite food, micro-organisms can utilize as sources of energy even such substances as paraffin, methane or hydrogen. Incidentally, it may be noted that this fact proves that food used for energy purposes does not become a chemical constituent of the protoplasm itself, any more than the petrol becomes a part of the motor. Now, are we certain that in cultures grown in a medium, which is normally so little acted upon that we say there is no action, there may not be a few individuals capable of such action in a small degree? If so, these would survive and the process might proceed according to the ordinary law of survival of the fittest. It may be possible to surmount this difficulty, but more convincing proof of adaptation would be given by results obtained on the same individual, by experiments on the lines of Abderhalden's "protective enzymes." Unfortunately, this observer has not yet shown the production of a new enzyme in response to the introduction of a foreign substance into the body. If an enzyme which is definitely known not to be present anywhere in the body were found to be produced, the results would be more to the point. On the contrary, more and more discredit is being cast upon Abderhalden's results even with foreign proteins, as in the much-advertised "pregnancy test."

The appearance of new diseases is a cognate problem, and it is discussed by Professor Adami in a very interesting manner. But here again some doubt may arise as to whether these diseases might not have been extremely rare and failed to come to the notice of any observers who were capable of appreciating their nature. It is true that examination of mummies and so on has not revealed their existence.

The evidence from the phenomena of immunity appears at first sight to be of a powerful kind. But it seems to me that much further knowledge is needed before we are justified in drawing such far-reaching conclusions as that of direct adaptation. Professor Adami is very scornful of Weismann's "ids" and "determinants," but, after all, are Ehrlich's "ambooceptors" and "complements" in much better case? Great as were the services of Ehrlich in the early days, I often wish that some competent investigator with no knowledge of the "side-chain theory," or any other theory, would take up the study of immunity reactions. In this connexion we may note that a view of the constitution of living matter akin to the side-chain theory and the "biogen" theory of Verworn is advocated in the book before us. May I venture to suggest to the author that there is not much difference between the standpoint of structural organic chemistry and that of the pure morphologist? Professor Adami rightly insists on the necessity of the dynamic consideration of life, and theories of the kind referred to are becoming less and less acceptable as our knowledge of the mechanics of the cell increases. Do "biophors" possess "receptors" for paraffin and methane?

With regard to the persistence of changes once set up, it is to me a matter of wonder that a morbid process ever gets right again, rather than the reverse.

This review may seem to be more critical than appreciative. My desire is to induce all of those interested in the difficult problems discussed by Professor Adami to read the evidence for themselves. They will find it put in an interesting and instructive manner. The biological significance of the problems raised must be my apology should it be thought that too great a preponderance has been given to difficulties.

W. M. BAYLISS.

THE SPLEEN AND ANAEMIA.

The value of combined work in medical problems, though generally recognized, is perhaps more commonly carried into effect in America than in this country. The results of this method are well shown in the recent volume on *The Spleen and Anaemia*,² by R. M. PEARCE, professor of

research medicine, E. B. KRUMBHAAR, the assistant professor of research medicine, and C. H. FRAZIER, professor of clinical surgery in the University of Pennsylvania. Not only do these writers contribute separate sections on the experimental, clinical, and operative aspects of the subject, but the account of the experimental work is a summary of investigations, directed by Professor Pearce, into the relation of the spleen to haemolysis, blood regeneration, and haemolytic jaundice, and carried out since 1912 by various collaborators, including J. H. Musser, jun., in the Research Department dedicated to his father. The results thus obtained have been published in some twenty papers, mainly in the *Journal of Experimental Medicine*.

The book before us deals with the influence of the spleen, as shown by its removal, on the red blood corpuscles, and not with the pathology and all the diseases of the organ. It is dominated by the results of experimental research, which are set forth in detail with full reference to the results of other investigators, and occupy more than half the volume. After experimental splenectomy the red blood corpuscles show increased resistance to haemolysis, and haemolytic jaundice and haemoglobinuria are less readily induced than in normal animals. As the hypothesis of a free haemolysin in the spleen is the basis for splenectomy in haemolytic anaemias, the available data are carefully considered, and experiments undertaken with splenic extracts failed to show the presence of a haemolysin in the spleen. Splenectomy is followed by a secondary anaemia, and it is suggested that the increased resistance of the red cells is not due to the absence of the spleen but is in some way, at least in part, associated with the anaemia. There is a post-operative leucocytosis of the polymorphonuclear type, the lymphocytes later showing a slight increase. Metabolism after splenectomy, both experimental and curative, is given detailed consideration.

In the clinical section Dr. Krumbhaar, after remarking that the term "splenic anaemia" should be either discarded or its use restricted, as it is loosely employed for a group of diseases, suggests the following classification with an eponymous nomenclature: Gaucher's disease or large-celled splenomegaly; Banti's disease, in which is included the form ordinarily called chronic splenic anaemia of adults, and in its final stage complicated by hyptic cirrhosis; von Jaksch's anaemia infantum pseudo-leukaemica, which is dismissed as in all probability not a condition but an atypical response of the infantile haemopoietic system to primary diseases of the blood; and the two forms of haemolytic jaundice, the acquired (Hayem-Widal) form and the congenital or familial (Chauffard-Minkowski). The first two are due to imperfect formation of blood, the last two, of course, to haemolysis. In the chapter on the indications for splenectomy it is pointed out that this operation should not be done for polycythaemia in which there is hyperplasia of the red bone marrow and the spleen acts as the chief agent in keeping the plethora within the limits compatible with life.

The question of splenectomy in pernicious anaemia is ably discussed; the reports of some of the early successes have not been confirmed by subsequent information, some of the cases may have really been examples of haemolytic jaundice, and under the heading of pernicious anaemia there may be included different types, some of which are and some of which are not benefited by splenectomy. But on the whole, though a cure cannot be promised, splenectomy is in many instances not only justifiable but advisable. The account of the operative procedure of splenectomy is well illustrated by figures. In conclusion, this volume is a valuable summary of recently acquired knowledge.

At a meeting of the Hamburg Medical Society last year the chief subject for discussion was the oedema frequently observed as a result of war conditions. It was regarded by one speaker as due to inanition, and provoked by absorption of excess of fluid in the war diet and by a reduction of the fat in the blood leading to damage to the capillaries of the skin. He compared the consequent oedema with that seen in chronic malaria and tuberculosis. Another speaker said that war oedema was most common in adult males between the ages of 50 and 70. Children were practically immune, but during the last year of the war he had found growth and development retarded between the ages of 12 and 14.

BRITISH EQUIVALENTS FOR GERMAN MEDICAL SUPPLIES.

II.

It is not pretended that the products named in the previous article form a complete list of British achievements in chemical manufacture during the war. They have been given as indicating the spirit in which the manufacturers have approached an intricate problem. This spirit is not confined to the home country, for we learn that the Diarsenol Company of Toronto, Canada, has succeeded in making compounds to which they give the names diarsenol and neo-diarsenol, which are identical with the German salvarsan and neo-salvarsan. We are informed that the company has fixed an even higher standard than was advanced by German manufacturers, and that it has received a licence from the British Board of Trade on the same lines as the other manufacturers mentioned in the first instalment of this article. The Local Government Board has recently approved neo-diarsenol for the purposes of the Public Health (Venereal Diseases) Regulations, 1916. The price of the drug has been fixed, and it can be obtained from Mr. G. R. Brown, 15, Edmund Place, Aldersgate Street, E.C.1.

A number of other chemical firms, working on the same lines as those already described, have quite a long list of new medicinal chemicals to their credit. May and Baker, Limited, who, as already stated, are the agents in this country for arsenobenzol-billon and nov-arsenobenzol-billon, which are salvarsan and neo-salvarsan equivalents, also produce at their Battersea works adalin, a hypnotic designed to take the place of veronal, and also paraldehyde and xeroform.

A number of products, thirty or more, including salicylic acid, aspirin, calcium acetyl salicylate (soluble aspirin), digitalin, glycerophosphates, phenacetin, salol, as well as atropine, homatropine, hyoscine, and hyoscyamine, and their respective salts, have been manufactured by Boots Pure Drug Company, Limited, at Nottingham, since the war began, and are all preparations which were obtained either wholly or in part from Germany before the war. Boots are manufacturing, in addition, other synthetic drugs, such as chloramine-T, dichloramine-T, and halazone, the new antiseptic substances described by Dr. Dakin in our columns.

Not only with regard to drugs but also to medicinal waters, for which we relied to a great extent upon Germany and Austria-Hungary, the deficiency resulting from the stoppage of Continental supplies has been made up. A successful effort to substitute a British product for the German and Hungarian aperients has been made. Experimental borings at Harrogate have discovered a valuable spring, which Professor Percy Frankland, F.R.S., of Birmingham, has testified to be of a very high degree of organic purity. The water, bottled and standardized, has been placed on the market, under the name of Aquaperia, by Camwal, Ltd., of London. The same firm is manufacturing siphon tops and fittings of pure block tin, previously largely imported from Germany. An important article in which this country has become self-sufficient is the filter, thanks to the British Pasteur-Chamberland Company, the Fulham Pottery and Cheavin Filter Company, and other firms.

Turning to a totally different range of medical supplies, we find that the British manufacturer was able in a little time to adjust himself to an exceptional demand. Before the war the x-ray apparatus used in this country was to a considerable extent constructed in Germany. Some of the most popular x-ray tubes were German, and so far as apparatus for single-flash exposures was concerned, Germany had an almost exclusive market. She also had the field largely to herself in the construction of instruments for estimating exposure and dosage. During the two years previous to the war the total value of exports from Germany of electrical apparatus for medical and dental purposes was more than £400,000, and the United Kingdom was the third largest importer. In this country only two or three firms were actual manufacturers of x-ray apparatus; the remainder were importers of the apparatus from abroad, not only from Germany, but from France and America, and even the apparatus which was put together in this country was largely dependent on Germany for the material.

Since the war there has been considerable activity and

progress, all the more gratifying because among the few British manufacturers of this class of apparatus it has taken a definitely co-operative instead of a competitive form. A special section of x-ray manufacturers has been formed within the association representing the interests of the electrical trade as a whole, and the manufacturers in their effort to furnish a British equivalent for the German supplies have had not only the help of some noted physicists, but also the guidance and active support of a Government department. The Ministry of Munitions has interested itself in the whole question of x-ray tube construction, and the optical and glassware section of that Ministry has collaborated with a subcommittee of the manufacturers. A laboratory has been set up by the Ministry and equipped by the manufacturers with the object of carrying out research work for the improvement of manufacturing methods. The research has been largely occupied with a view to making in this country a suitable glass for the construction of tubes, and now everything connected with the x-ray tube can be produced here, including a satisfactory quality of tungsten. Originally the glass was of poor quality, gave blue instead of green fluorescence, and was very vitreous, but all the glass now made is remarkably good. The construction of the tube was the most difficult problem of all in the field of x-ray and electro-medical manufacture, but it has been surmounted, and, to mention only one firm, Cuthbert Andrews has placed on the market heavy-anode tubes made of British glass with all the characteristics of the best German glass. In the same way the manufacturers are turning out induction coils and transformers which are just as powerful and efficient as the instruments previously obtained from Germany, and apparatus for the single-flash exposure is now being constructed here from an improved design, as well as all the various accessories which go to form an x-ray unit.

One quite new industry so far as this country is concerned has sprung up under the stress of war conditions. This is the making on a large scale of fluorescent and intensifying screens. Before the war fluorescent and intensifying screens in platinocyanide of barium were chiefly of German production. One British firm, Watson and Sons, equipped a laboratory, placed it under the control of a well-known photographic chemist, Mr. Thorne Baker, F.C.S., and eventually established a works where grainless and rapid screens are now being successfully made, and more than replace the previous German screens in respect of quality and speed. Harry Cox and Company, Limited, also have placed on the market fluorescent and intensifying screens of very fine surface.

The same thing holds good of delicate instruments of precision, including some appliances for localization, and also measuring instruments. One of the instruments widely used for measuring the penetration of x-rays was known as the Bauer qualimeter, a unipolar electrostatic voltmeter connected to the cathode terminal of the tube. An application was made by Newton and Wright, Limited, to the Controller of Patents, to have the German patent revoked in their favour, and a licence was duly granted to manufacture. The instrument has now been made here for some time past, and a royalty paid to the Board of Trade for the working of an enemy patent.

Apart from instruments and appliances definitely associated with x-ray work, a good deal of electro-medical apparatus was, previous to the war, imported from Germany, and is now made in this country. Seeing that the more general apparatus of this kind (as distinct from some special items like those already mentioned) is made by a group of manufacturers who have pooled their knowledge and work together for the advancement of this young industry, little purpose would be served by specifying individual firms, but it may be said that the range of articles now manufactured here—and before the war largely imported from Germany—includes milliamperemeters for measuring currents passing into a patient's body; apparatus working both from batteries and mains for the production of faradization, galvanization, and electrolysis; various surgical appliances, such as cautery instruments, and the apparatus for producing the correct current for these instruments. The same is true of orthopaedic appliances for mechanotherapy, apparatus needed for baths and massage, and, not least, instruments for the production of ultra-violet light. The delicate mechanism necessary for

this last, involving the use of mercury vapour lamps, has been most successfully constructed over here.

Surveying the whole of this field, it may be said that practically everything in the nature of electro-medical apparatus is now made in this country. Furthermore, standardization is much easier when all apparatus is manufactured here and the manufacturers are in close association, than when part is manufactured here and part is imported.

Among surgical appliances generally, one instance of definite substitution may be noted. This is the "Record" hypodermic and antitoxin syringe, for the making of which S. Maw, Son and Sons have put down a special plant. These syringes are now being turned out in large quantities, and, it is claimed, are of a better quality than the former German-made article.

In the first part of this article it was stated that atropine, homatropine, and eserine, were probably exclusively of German manufacture before the war. Messrs. Burroughs, Wellcome and Co. inform us that they had made certain alkaloids on a commercial scale at an earlier date. Thus they commenced the manufacture and sale of pilocarpine and its salts in 1900, of atropine and its salts and of eserine and its salts in 1901, and of homatropine and its salts in 1905. In 1911 they were able to execute from stock of their own manufacture a single order for 176 oz. of eserine sulphate. At the outbreak of the war they had a stock of over 600 oz. of atropine and its salts of their own manufacture. The same firm manufactured the original quantities of emetine bismuthous iodide required by the Medical Research Committee for the investigation into the value of the drug in dysentery. The firm has since manufactured and issued this salt in large quantities.

THE MILITARY SERVICE (MEDICAL PRACTITIONERS) REGULATIONS, 1918.

THE Local Government Board and the Secretary for Scotland have issued identical regulations¹ with regard to applications concerning medical practitioners for exemption from military service. The regulations, which came into force on May 23rd, provide for the appointment of a special medical tribunal for England and Wales, and another for Scotland, to deal with all applications for the grant, renewal, or review of certificates of exemption to medical men of military age. It is the intention of the Director-General of National Service to approve the existing Central Medical War Committee and Scottish Medical Service Emergency Committee as the medical tribunals. As in the past, applications concerning members of hospital and medical school staffs in the metropolis will be referred to the Committee of Reference appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England, whose recommendations will be binding upon the medical tribunal.

Power is given to the tribunals, with the approval of the Director-General, to appoint or recognize local professional committees to assist in the investigation of areas and of individual cases.

In dealing with applications, the tribunal may hear witnesses, and receive written statements, and the applicant has a right to be heard in person or through a representative, and to put relevant questions to witnesses.

Application for the grant or renewal of a certificate of exemption may be made on any of the following grounds:

(a) That it is expedient in the national interests that the practitioner should, instead of being employed in military service, be engaged in other work in which he is habitually engaged; or in which he wishes to be engaged; or, if he is being educated or trained for any work, that he should continue to be so educated or trained.

(b) That serious hardship would ensue if the practitioner were called up for army service, owing to his exceptional financial or business obligations or domestic position.

(c) Ill health or infirmity.

(d) Conscientious objection to combatant service.

Applications must specify all the grounds, whether occupational or personal, on which exemption is claimed, with a full statement of the reasons on which the claim is

based; they must be made in duplicate on the prescribed form, and must be sent to the appropriate medical tribunal. Where some other person applies on his behalf the practitioner must join in the application and sign the form. Applications must be made within fourteen days of the date on which individual notification is sent to the practitioner by the Director-General of National Service. Before applying for renewal or variation of a certificate, leave to apply must first be granted by the medical tribunal; in ordinary cases such request must be duly made and delivered within four days of the expiration of the certificate. The Director-General may require the medical tribunal to review the case of any practitioner holding a certificate. With the assent of the Director-General the tribunal may grant, renew, or vary a certificate without hearing the case, if satisfied that the grounds of application have been established. They will hear all other cases, four clear days' notice being sent both to the applicant and to the practitioner, where these are not one and the same person.

Regulation 24 lays down that "a certificate of exemption may be absolute, conditional, or temporary, as the medical tribunal think best suited to the case, . . . provided that—

A certificate granted or renewed on occupational grounds shall, and a certificate granted or renewed on personal grounds may, be subject to the condition that the practitioner shall undertake such professional service and under such conditions as the Director-General of National Service may, after consultation with the medical tribunal and in concert with any Government Department concerned, from time to time deem best in the national interests."

The importance of this proviso scarcely needs emphasis. In every case the decision of the tribunal will be communicated at once in writing to the applicant, to the practitioner, and to the Director-General. Where it is decided to grant a certificate this will be issued to the practitioner concerned; but if leave to appeal against their decision is given by the medical tribunal a certificate will not be issued or withdrawn pending the final decision of the case. Every certificate of exemption will state the ground or grounds on which it is granted, the date on which it will expire, if temporary, and the conditions, if any, on which it is granted; and in giving a certificate the tribunal may direct that the holder shall not be liable to join the volunteer force. The clerk to the tribunal may issue, on payment of a fee of 1s., a duplicate of a lost, destroyed, or defaced certificate. Power is given to rehear cases with the consent of the Director-General. Lastly, the regulations apply to voluntarily attested and enrolled medical men equally with other practitioners.

MEDICAL EXAMINATION.

The Director-General of National Service on May 22nd issued directions requiring qualified medical practitioners of military age—that is, those born after April 18th, 1862—to report themselves for medical examination on receipt of individual notice duly served on them. It is expressly stated, however, that a practitioner will not in any event be called up for military service until he has been sent by the Ministry of National Service a further notice specifying the time for the making of an application for a certificate of exemption, and until any application which may be made in accordance with the notice has been disposed of by the medical tribunal. Such application must be made within fourteen days of the date of sending such further notice, and no practitioner need take any steps to apply for exemption until such further notice is sent to him. The above directions were announced in the advertising columns of the JOURNAL last week, p. 26.

THE new building of the medical college of Cincinnati University was formally opened on February 25th. It was erected and equipped at a total cost of approximately £120,000.

THE Surgeon-General of the United States Navy has framed a scheme for increasing the accommodation in naval hospitals. Some 15,000 extra beds have been provided, and it is proposed to augment this number by 8,000 beds, together with 3,270 beds for the hospital personnel. The naval medical officers are in charge of two hospitals in France, each with 500 beds, and arrangements are being made to establish three naval hospitals in England, each with 1,500 beds.

¹ To be purchased through any bookseller, or directly from H.M. Stationery Office, at Imperial House, Kingsway, London, W.C.2; 28, Abingdon Street, London, S.W.1; 37, Peter Street, Manchester; 1, St. Andrew's Crescent, Cardiff; and 23, Forth Street, Edinburgh. Price 1d.

British Medical Journal.

SATURDAY, JUNE 1st, 1918.

MEDICAL PRACTITIONERS AND MILITARY SERVICE.

THE regulations governing the position of medical men under the new Military Service Act have now been issued, with effect from May 23rd, and their main provisions are briefly described this week at page 622. We believe that in the course of the next few days the Ministry of National Service will issue a memorandum to members of the medical profession explaining at some length the purpose of these regulations, and the procedure which is to be based on them. It is already almost a truism to say that the new Act—which raises the age of military service for medical men to 56—will affect, either directly or by a side wind, the work and life of every practitioner in the country, and it is important that all should study carefully the facts of the situation. We can only hope that the documents prepared for their guidance by Government departments will clarify rather than confuse the issue.

In the first place it is to be noted that the Central Medical War Committee and the Scottish Medical Service Emergency Committee, which have hitherto been so in all but name, are now made special medical tribunals for dealing with applications for exemption from military service on behalf of medical men; that the Committee of Reference keeps its name and its functions under the new regulations; and that power is given to retain the valuable assistance rendered by the local medical war committees. The grounds of exemption, though more precisely defined, and now including the plea of conscientious objection, are in substance those previously recognized by the professional committees. The status of the medical tribunal is in many respects that of an ordinary appeal tribunal, but the hearing of cases will follow the lines already laid down. An appeal on personal grounds against a decision may, however, be made to the Central Tribunal, with the leave of the medical tribunal, or on the recommendation of the Committee of Reference; but "it is not intended that cases shall come before the Central Tribunal unless important questions of principle are involved, or unless there is some other special reason why an appeal should be allowed."

With regard to the kind of exemption from military service which may be granted, the regulations include a special provision whereby exemption on occupational grounds shall, and on personal grounds may, be conditional on the practitioner undertaking such professional service and under such conditions as the Director-General of National Service may, after consultation with the medical tribunal and in concert with any Government department concerned, deem best in the national interests. This stipulation leads straight to the root of the whole matter, for it is evident that nothing short of national necessity could justify a measure which will at once be recognized as vocational conscription, howsoever cloaked in legal or departmental language. At the same time an official assurance has been given that "the regulation

in question will be administered with the utmost consideration consistently with the national interests, and that any arrangements under it will be made in full consultation with the medical tribunal." For the enlightenment of those who have not closely followed the subject, the case can be briefly stated. It is held, and with good reason, that the medical profession is in a special position, the effect of which, however, cuts both ways. Doctors are so much in request, both for military and for civilian service, that the needs of the country can only be met by a carefully considered distribution of the medical personnel. Hence the necessity for a special medical tribunal to hold the balance between military demands on the one hand and civilian claims and personal objections on the other. Hence also the differential treatment of the medical profession in respect of the age limit for military service, and the "conditional exemption" which is all that most doctors of military age can look for from their professional tribunals. These and other aspects of the new legislation were considered by Sir Donald MacAlister in his presidential address before the General Medical Council, which we report in the SUPPLEMENT this week.

The procedure to be adopted, and the principles which underlie it, will perhaps be made clearer in the following way: While all medical men up to the age of 56 are liable to military service, it does not necessarily follow from the terms of the Act that they must be employed as doctors, however desirable that may be. The question before the medical tribunal will be the same as that before ordinary tribunals—namely, whether the individual shall serve in the army or shall receive exemption on one of the statutory grounds—occupation, personal hardship, ill health, or conscientious objection. Unless a case is made out on one or more of these grounds the medical man becomes liable to join the army, the disposal of his services resting with the military authority. But since the present shortage of doctors makes it inadvisable that a medical man should be employed in non-medical work, the authorities do not propose to call up doctors for service in the ranks provided that they undertake to render medical service either in a civil or a military capacity if called upon to do so by the Ministry of National Service after consultation with the professional committee. Civil medical service is understood to mean work of a medical nature either in the district in which the doctor lives or at a distance, undertaken with a view to setting free a younger or otherwise more suitable practitioner for military medical service.

We understand that, in order to carry out such rearrangements as are necessary with the least disturbance and friction, the Ministry of National Service proposes at the expiry of fourteen days' notice to issue a certificate of protection to every medical man of the new military age in respect of whom an application has not been made on personal grounds within that period. The effect of this procedure will be that each practitioner receiving a certificate is left to continue his present work unless and until he is called upon to serve in some other way. If he considers that he should receive some other form of exemption within the terms of the regulations he must within fourteen days send to the clerk of the appropriate medical tribunal notice to this effect, in which case his application will be heard by the tribunal in due course. If, however, he decides to accept the certificate of conditional protection he will be left to carry on his present work until such time as it appears

necessary to call upon him to serve in some other direction, either as a commissioned medical officer, or by taking over the work of a neighbour or neighbours under some scheme of local arrangement, or by being transferred to some other district where there are doctors more suitable for military service but who cannot under present conditions be spared from civil life. The possibility that he might be called upon to serve with the army in a non-medical capacity need only be considered in the case of a doctor who, being deemed surplus for the medical needs of his area, is unwilling to accept one of the three forms of service indicated above.

If and when the need arises for utilizing his services in one of these ways, the practitioner will be able to appear before the local or central professional body and state his reasons for not being assigned to the new duties required of him, in the same way as has hitherto been adopted in regard to enrolled practitioners. It will be noticed that the professional bodies recognized as medical tribunals under the regulations are assigned two distinct though related sets of duties—namely, the duties pertaining to an ordinary tribunal constituted to deal with claims for exemption from military service, and the duties of a body advisory to the Director-General of National Service in dealing at a later stage with the cases of doctors who have received certificates of conditional exemption under the proviso to Regulation 24.

PROTEIN "SHOCK" THERAPY.

ALTHOUGH some forms of treatment formerly empirical have now been sanctified by an explanation of their mode of action, an interesting essay might still be written on cures due to treatment logically inefficient or even smacking of quackery. Thus at a laparotomy on an acute abdomen nothing particular is found or done, and yet the patient seems to improve because of, rather than in spite of, the somewhat vigorous interference. Possibly in such cases the surgeon has operated better than he knew and unconsciously remedied some mechanical factor, such as a twist or adhesion, or conceivably an accessory factor in the ritual—such as the infusion of normal saline—has modified a general infection or toxæmia responsible for prominent abdominal symptoms. In tuberculous peritonitis the benefit from a simple laparotomy is clear to every surgeon, but the *modus operandi* perhaps concerns him less than the incision.

For a considerable time the thoughtful practitioner must have been perplexed by the success which undoubtedly may follow the injection of some preparations, such as polyglandular extracts, or vaccines and serums, that are multiple both as regards their derivation and the diseases for which they are recommended. In 1906 Montgomerie Paton advocated on clinical grounds the oral administration of antidiphtherial and normal horse serum in the treatment of various infective diseases, and stated that the resistance of the organism to infection was thereby increased. A little later horse serum was advocated by E. C. Hort in gastric and duodenal ulcer in virtue of its antiautolytic action; later Hiss and Zinsser injected extracts of leucocytes in infectious diseases, and the nuclein treatment had a short vogue.

While the spirit of scientific medicine naturally views with suspicion therapeutic measures unsupported by reasoned exposition, it should always be ready to investigate with an open mind apparently haphazard methods of treatment so as to obtain a guide to future advance, for the germ of truth may remain hidden

under obvious empiricism or quackery unless sought for. The logical attitude of practically restricting treatment to those forms that are demonstrably specific, mainly due to Ehrlich's and Sir Almroth Wright's exact methods, is now orthodox, and is perhaps the reason why the numerous researches and papers, especially those by Jobling and Petersen¹ on the non-specific factor in the treatment of disease and protein shock therapy, have received comparatively so little notice. Typhoid fever has been treated by intravenous injections of typhoid vaccine, of chicken serum, and of protease, and by intramuscular injections of boiled milk; and all these medicaments have been followed by a crisis and great improvement in the condition of those patients. Acute arthritis has likewise been cured by intravenous injections of typhoid vaccine (Miller and Lusk), and also by similar injections of albumose. In Culver's hands gonococcal arthritis reacted equally well to meningococcal vaccine and to gonococcal vaccine. Even more recently Cecil² has given a careful account of 40 cases of acute arthritis treated by intravenous injections of typhoid or gonococcal vaccine. Thirteen cases of rheumatic arthritis rapidly recovered after typhoid vaccine (in 3 cases one injection, in 4 two injections, and in 1 three), 20 cases (17 rheumatic fever) required salicylates as well, and all but 3 showed improvement while receiving the vaccine. Seven cases of acute gonococcal arthritis showed gradual improvement under vaccine treatment (3 gonococcal vaccine, 2 typhoid vaccine, 2 both), but it is cautiously added that it was impossible to say how far the vaccine was responsible. He concludes that this method is undoubtedly efficient in many cases of acute arthritis, but as the reaction is severe, unpleasant, and may be dangerous if the cases are not carefully selected, it should be advised only after salicylates and other well established means have failed.

It seems generally agreed that the beneficial results obtained by these methods of non-specific treatment depend roughly on the occurrence of a good reaction with shivering, fever, and perspiration. These surprising results suggest, at any rate in the case of arthritis, that the vaccine acts in virtue of the foreign protein it contains and not specifically. Hence the conception of non-specific protein "shock" treatment, or, as the subtitle of an article by L. D. Smith expresses it, "Allergy, a therapeutic agent." According to Jobling and Petersen a reaction to injection of a foreign protein, such as is contained in a vaccine, causes changes in the tissue cells, especially of the haemopoietic organs, and in the blood—namely, leucocytosis and fluctuations in the ferment-antiferment balance; during the protein shock a condition (low antiferment and increased protease) obtains which favours proteolytic activity such as would hydrolyze the toxic bacterial products to their lowest non-toxic forms, whereas after the reaction the reverse condition (increased antiferment and low protease) holds good. It may be mentioned that Sir Almroth Wright³ found that the antitryptic power of the blood was increased after typhoid, streptococcal and staphylococcal vaccination, that this antitryptic power of the blood inhibits blood infection, and that vaccines may give some protection against diseases other than those they are designed to ward off.

In his most recent paper Petersen⁴ quotes the work of Friedberger, Matthes, and Vaughan, to the effect

¹ J. W. Jobling and W. F. Petersen, *Journ. Exper. Med.*, Baltimore, 1914-15; also *Arch. Int. Med.*, Chicago, 1917, xix, xx.

² R. L. Cecil, *Arch. Int. Med.*, Chicago, 1917, xx, 951-963.

³ A. E. Wright, *BRITISH MEDICAL JOURNAL*, 1915, ii, 632.

⁴ W. F. Petersen, *Arch. Int. Med.*, Chicago, 1917, xx, 715-724.

that in infection no intoxication occurs until the host becomes sensitized to the bacterial protein; and that if, when this refractory or incubation period is finished, the patient is desensitized as the result of protein shock, the fever and other symptoms disappear though the micro-organisms remain, as has been shown in the case of typhoid fever. In order to cover this therapeutic conception of seeking to change the reacting powers of the host instead of modifying or destroying the invading parasite, the term "ergotropie" has been coined by von Groer. The mechanism, application, and limitations of non-specific protein treatment, and especially its relation to vaccine therapy, require much more investigation before its adoption in practice can be set on a firm basis; and, in any event, this new knowledge will in no way impugn the value of established specific remedies such as antidiaphtherial, antitetanic, anti-meningococcic, and antipneumococcic (type I), serums, quinine, salvarsan, and emetine. Petersen, who is investigating the subject further, concludes meanwhile that the good results of protein shock therapy should not be ascribed to any one alteration in the reacting organism but to a series of factors—namely, antibody and ferment changes in the serum, leucocytosis, fever, sweating, increased flow of lymph through the thoracic duct, and the cellular changes which are no doubt important though as yet intangible.

THE ARMY MEDICAL SERVICE IN FRANCE.

It has been announced by the Secretary of the War Office that the Army Council has not considered it advisable to extend the period of service of Lieutenant-General Sir A. T. Sloggett as Director-General. This decision, which the official announcement states is due to the fact that Sir Arthur Sloggett has completed the period of his appointment and passed the age limit for service on the active list, will be received with great regret by those who have served under him in France and recognize the great success of his administration. His successor as Director-General Medical Services, British armies in France, is Major-General C. H. Burtchaell, a medical officer who has had wide experience in India, in South Africa, and at home. Sir Arthur Sloggett's career has been one of very great distinction. He was a student of King's College, London, of which he is now a Fellow, and entered the Army Medical Service in 1881. Three years later he was serving on the Indian frontier, and in 1896 was senior medical officer of British troops with the Dongola Expeditionary Force. He served in the Sudan in 1897-98 and was dangerously wounded at Khartoum, being shot through the chest in the cardiac region. He made a complete recovery and served with great distinction in South Africa. Afterwards he was P.M.O. of Home and London Districts, and of the 6th Division in India. He became Director-General of Medical Services in India in 1911, and passed from that appointment to become Director-General A.M.S. at the War Office on June 1st, 1914. Since October, 1914, he has been in France as Director-General Medical Services of the British armies in that country. His administration has been conspicuously successful, largely, as we have on many occasions pointed out, owing to his appreciation of the importance of scientific methods in the prevention and treatment of disease, and his sympathy with the views and aspirations of the medical officers from civil practice who have served under his command. His successor, Major-General Burtchaell, graduated at the University of Dublin in 1889, and entered the army in 1891. He was through the North-Western Frontier campaign in India in 1897-98 and was present at all the principal actions, including the Dargai Heights, being

promoted Major for his services in the field. He served throughout the South African war with Lord Methuen's command, being present at the actions on the Modder River and Magersfontein, and in 1902 was selected for appointment as principal medical officer to the South African Constabulary, a post he retained until 1905, when he rejoined the army. While serving on Headquarters Irish Command, 1907, he organized the experimental scheme of sanitary training for fighting troops, afterwards adopted for the army, and in the following year directed the medical service work of the first medical tour held in the British army. In 1910 he became Assistant Director-General, Army Medical Services, War Office, and continued to take special interest in arrangements for medical manoeuvres and tours. He has served as Assistant Director-General Medical Services in France since October, 1914. He was promoted Colonel in March, 1915, and temporary Surgeon-General in October, 1917. His promotion was made substantive in the following December. For his services in the present war he has been mentioned seven times in dispatches, and has been awarded the C.B., the C.M.G., and the Legion of Honour. During his service in South Africa General Burtchaell came in contact with the Dominion forces for three years, and his association with them in France, especially with the Canadians, dates from 1915. The Canadians went into action at Ypres for the first time, and a correspondent tells us that in a situation which was strange and difficult the Canadian Medical Service felt that it could rely implicitly upon General Burtchaell's experience and sympathy, and that that sympathy has ever since grown more close.

MEDICAL MAN POWER IN THE UNITED STATES.

From editorial articles in the *Journal of the American Medical Association* of April 20th and 27th it is interesting to note that the medical profession in America is going through the same stages in relation to the war as was the case in this country. Thus, at the outset the Association offered its services to the Government, just as did the British Medical Association nearly three years before. In each case the volunteers were at first sufficient to cover the immediate needs. Now, as we recorded a fortnight ago (p. 569), Surgeon-General Gorgas has made a request for 5,000 more medical officers, just as in March, 1915, Sir Alfred Keogh, the Director-General A.M.S., asked for 2,000. The American Association, like the British Medical Association, has a War Committee, which is taking up this call with energy and enthusiasm. The Surgeon-General desires that the 5,000 volunteers shall be secured without serious hardship to any "community, manufacturing concern, or other civil activity," and consequently the American Medical Association has begun to investigate the position in all parts of the country, so as to produce a survey which will "provide a basis for active, intelligent, co-operative effort." In contemplating the problem of supplying not only the immediate, but also the future needs, the War Committee deliberated on the advisability or necessity of calling for a "voluntary draft" of all medical men under 55 years of age. This would mean that every medical man in active practice would volunteer as a member of the Medical Reserve Corps and be subject to call for such military or civilian duty as he may be deemed best qualified to discharge and as conditions and necessities may require. In other words, a scheme of enrolment or "voluntary conscription" was mooted, but of wider scope than the enrolment scheme of the Central Medical War Committee, inasmuch as it included enrolment for civil work, and was applicable to men of a higher age. The American Medical Association has deemed this extreme measure unnecessary for the present at least, but the organization of such a scheme would have afforded excellent training for the work the Association will have to face if ever it becomes necessary in America to pass a Military Service Act in any way comparable to that which has been found necessary in Great Britain. Though the

number of medical practitioners in America is large—the Association itself can boast 81,000 members—there is reason why organization for civil as well as military necessities, such as is contemplated in this country by the Ministry of National Service, will be required at a relatively earlier date in the United States. For, unlike ours, the main American army is fighting some thousands of miles from its own country. The bulk of its hospitals must be in Europe, so that the proportion of doctors to troops must be considerably greater than with us. Finally, our contemporary asserts that “the time has come for every medical man under 55 years of age, who is physically qualified, to consider seriously for himself the question of his duty to his Government.” We have always held that no individual practitioner can possibly judge for himself the medical needs of the community in which he practises, or the hardship which he himself will suffer. For these reasons we are convinced that unless the war ends speedily the War Committee of the American Medical Association might have been better advised to take the matter in hand at once; it would at least have gained experience and much valuable information from the experiment. The magnitude of the work undertaken by the medical department of the American army during the first year may be judged from a few statistics. Thus the number of military hospitals in the United States has been increased from seven to fifty-three, with a bed capacity of 53,400, and in France from nothing to a bed capacity of 25 per cent. of the strength of the expeditionary force. The number of medical officers has been increased from 900 to 19,000, and that of nurses from 375 to 7,000. The laboratories have been increased from 112 to 650. The medical department has examined more than 2,000,000 men. The death-rate from disease has been 6.6 per 1,000, which is lower than the death-rate for men of the same age in civil life.

THE REGISTRATION OF UNIVERSITY ELECTORS.

The appeal now being made to graduates serving overseas to register as electors of universities, and the suggestion that relatives of such graduates as may not be following events at home, should obtain forms for them, carries an important reminder of the right of voting by proxy, which may be exercised at a general election if circumstances prevent the ordinary course being taken. The procedure for university elections is under the direction of the governing body of the university, but its operation has been very carefully defined in the new Act. Voting papers, as previously, take the place of ballot papers. In an election they can be delivered by the voters personally or by post. The form of the paper is set forth in the statute. It includes a declaration by the elector, and a declaration by a witness that the signatory is personally known to him. Provision is made under Section 36 of the Act that persons entitled to vote in university elections may do so by proxy, when their position is the same as that of persons entitled to vote by proxy in other parliamentary elections. To enable voting by proxy in elections other than those of universities a returning officer must prepare an “absent voters’ list”; but the registrar of a university is not required to do this—the right to vote by proxy is recognized as if such an absent voters’ list had been prepared; the fact that voters have to register—the electorate for the time being thus constituted—is obviously deemed sufficient to enable the issue by the registrar of proxy forms as they may be asked for from the roll he has thus obtained. The provision as to absent voters is set out in Clause 23, which in effect provides that an Order in Council may direct that voting by proxy by naval or military voters shall be permitted in any area on land abroad mentioned in the Order if it appears that “ballot papers” (in the case of university electors “voting papers”) cannot reasonably be returned before the votes are counted. The right to vote by proxy also applies,

in limited degree, to the merchant service and to fishermen. No person is allowed to vote for more than two absent voters unless this person be husband, wife, parent, brother, or sister of the elector. It is the duty of the registration officer (in the case of universities it is the registrar’s duty), on any application for a proxy paper, to issue it to the applicant or to some person on his behalf if satisfied that the person concerned is registered and entitled to appoint a proxy. This paper is to remain in force during the continuance of the present war or for a period of twelve months afterwards unless cancelled. A proxy paper may be cancelled by an elector who gives notice in prescribed form. But the one essential matter for the moment is to register. The method of voting—by voting paper by post, or by proxy paper, as explained—is determined later, according as circumstances may require.

ACTION OF ANTISEPTICS ON BACTERIAL TOXINS.

There is little evidence at present that antiseptics can exert a destructive action on bacterial toxins, and in a preliminary note on this question Taylor and Austin¹ have related experiments with the soluble exotoxin of *Bacillus welchii*, the virulence of which Bull and Pritchett standardized. Having obtained a standardized toxin, inactivated horse serum and the antiseptic to be tested were added, the latter remaining in contact with the toxin for five minutes before the mixture was injected into the pectoral muscles of a pigeon. The series of experiments showed that Dakin’s hypochlorite and chloramine-T solutions will protect pigeons against multiple fatal doses of the *B. welchii*, whereas phenol 0.25 per cent. has no such action. These observations are not recorded with the intention of advocating the use of an antiseptic in place of the specific antitoxin described by Bull and Pritchett; the authors hold that in human surgery the antiseptic treatment of an infected wound should be combined with specific serum therapy. This preliminary paper has a bearing on a wide conception, which is a division of antiseptics into two groups: (1) such as phenol, possessing bactericidal power but little or no destructive influence on the products of bacterial activity, and (2) such as the chlorinated antiseptics, attacking chemically both the bacteria and their products, and, by an alteration or disintegration of the molecules of the latter, altering their properties and rendering them inert. As Dakin pointed out, the chlorinated antiseptics effect this by their affinity for the amino group of the protein molecule.

GERMAN EXPERIENCES OF GASSING.

At a meeting of the Hamburg Medical Society last year Dr. Knack² gave an account of the symptoms observed in cases of gassing. In several the acute symptoms were followed by marked general weakness, bouts of coughing, scanty mucous expectoration, and dull dragging pain in the chest. The x rays showed increased pulmonary markings, as observed in chronic bronchitis, while old tuberculous foci were apt to be stirred up. Two patients had recently been received from the Western front suffering from the effects of an unknown gas, liberated by the explosion of gas bombs thrown at a distance of 80 to 100 metres. The gas had a musty smell, tasted sweet, and was invisible. Its action was so rapid that most of its victims had not time to put on their gas masks. Many soldiers had died in a few minutes, convulsed. He showed two soldiers who had been gassed. They were unconscious for some hours, and had suffered for several days from violent vomiting. The respiratory symptoms were insignificant. After about fourteen days the legs became painful, and the patients felt giddy and rolled about when walking. A moderate degree

¹ H. D. Taylor and J. H. Austin, *Journ. Exper. Med.*, Baltimore, 1918, xxvii, 375–381.

² *Deut. med. Woch.*, September 27th, 1917.

of polyneuritis was demonstrable; the reflexes were weak and the large nerve trunks were very tender. The x rays showed increased pulmonary markings—evidence of peribronchitis. Lymphocytosis of 46½ per cent. was found, but neither in the blood nor urine could any pathological chemical substance be found by spectroscopic or other tests. Both patients had been slightly febrile for a considerable time. Another patient had been unconscious for several days after being gassed and had developed paralysis of the left arm and paresis of the left leg. Babinski's sign was present. The paralysis soon passed off completely, but the man was insane for a long time, passed faeces and urine involuntarily, and had not completely recovered. In this case also the result of search for a chemical poison was negative; only a trace of bile pigment could be found in the serum. Though in this case, too, the composition of the gas was unknown, Dr. Knack observed that the mental disturbances and the paralyzes were suggestive of carbon monoxide poisoning.

THE REPORTED EPIDEMIC IN SPAIN.

THE new conditions produced by war both at the front and in the civilian population, especially from the altered circumstances of diet, hygiene, and occupation, have led to the appearance of a number of fresh diseases. This extremely interesting subject has naturally attracted much attention, and at the present moment the cases recently described as botulism, poliomyelitis, and lethargic stupor are being keenly investigated. As novelty has specially attracted the public since, and probably before, the time of the Athenians, there is obviously a temptation for the press to publish early accounts of new diseases. Thus in the *Times* of May 28th King Alfonso is stated to have fallen a victim to a new disease which has attacked approximately 30 per cent. of his subjects. The symptoms are said to be high fever, vomiting, pains in the chest, and diarrhoea. So far there have been no fatal cases. The *Daily Mail* of the same date speaks of "a mysterious epidemic," and the *Morning Post* of "this new and strange outbreak, the germ of which has not yet been discovered." Pending further information it seems not improbable that this acute catarrhal disease is what we are accustomed to speak of as "influenza," and that in Spain now the gastro-intestinal form is prominent. During the month of May there has been a severe outbreak of influenza in a certain district of this country, recalling in the extreme suddenness of its incidence the beginning of the epidemic of 1889-90. The papers also report an outbreak of influenza among the German troops as one of the reasons to account for the delay of the recent offensive. The reference in the *Times* to the "plague of 1889" is very probably a reporter's error for the pandemic of influenza in that year, for there was no bubonic plague then in Spain. We cannot help feeling that in the absence of any bacteriological proof, the extreme low mortality or its practical absence, and the possibility that the disease is gastro-intestinal influenza, render alarmist suggestions premature, and they do not seem to be countenanced by the medical profession in Spain. The question of a pandemic of influenza is a sufficiently serious one, and on the grounds of probability should be excluded before a scare of cholera is raised.

HEALTH OF THE TURKISH ARMY.

LAST autumn Dr. His¹ gave the Medical Society of Berlin an account of the health conditions of the Turkish army. The organization of the army medical service was, he said, based on the German model; most of the civilian practitioners serving in the army had received their medical education in the French Jesuit school or in the American college in Beirut, where one British and one American doctor were still working. The nursing staff

was recruited from Christians and Jews, as Mohammedan women had not yet undertaken nursing. Baths and other appliances for combating lice were provided at all the military centres. Tetanus and gas gangrene were rare, owing, His thought, to the powerful insolation of the soil. The Turk was far more subject than the German to relapsing fever; the disease responded satisfactorily to salvarsan unless complicated by severe jaundice or symptoms of dysentery. In Constantinople amoebic and bacillary dysentery were equally common; in Asia Minor and Palestine the dysentery was amoebic only. Emetine had maintained its good reputation, and abscess of the liver was rare. Salvarsan had proved beneficial in tertian malaria only, and even in such cases was inferior to quinine. Pappataci fever was particularly prevalent in Aleppo. Typhoid fever was rare; a septic paratyphoid A infection was more common. Paratyphoid inoculation had proved harmless and apparently successful. Typhus fever was frequent at the early stage of the war only, and Turks and Arabs had suffered from the same death-rate as the Germans (12 to 15 per cent.). Weil's reaction had proved of diagnostic value. Gangrene, which in 1915 had been a common complication of typhus, had become very rare, though the reason was not known. Vincent's angina was strikingly common, but only among the Turks; it yielded to local treatment with salvarsan. This drug also proved useful in pyorrhoea alveolaris and uoma. Scarcely two dozen cases of war nephritis were observed in the whole field of operations. "War oedema" resulting from a diet restricted to bread and olives disappeared when vegetables were added to the dietary. Nervous disorders of heart and stomach and the host of other neuroses were practically unknown in Turkey, a circumstance which Dr. His attributed to lack of compensation and provision for such cases.

PROFESSOR HARVEY CUSHING.

At a meeting, on May 25th, of the Royal College of Surgeons in Ireland, which was attended by the Lord Lieutenant, Mr. Walter Long, M.P., and the Lord Chancellor of Ireland, the honorary fellowship was conferred upon Major Harvey Cushing, the eminent professor of surgery in the University of Harvard, who from an early date has rendered great services to the British and now to the American armies in France. In acknowledging the honour, Major Cushing said that he recognized it as an act of friendship towards his own country. America had realized that there was an insane nation embroiling the world by unbelievable ambition, and using every unbelievable means to attain its end. America was not in favour of half measures, and the universal feeling of its people was that they were in to stay to the end. After saying that America's neighbour, Canada, also was in as a country, he continued, "You here in this beautiful land are the next people to us, and we expect you to be in as a country, and you certainly will." After paying a high tribute to the gallantry of the Irish regiments in the war, he expressed the hope that the time was coming when there would be in Ireland a period of national service to help towards the smoothing out of those difficulties which must arise in every country. Such a period would awaken in the people a sense of that devotedness which could only come to them through service rendered to their country. Professor Harvey Cushing was elected an Honorary Fellow of the Royal College of Surgeons of England in 1913.

GERMAN BOMBING OF HOSPITALS.

MR. BONAR LAW, when asked at the opening of Parliament to make an official statement as to the bombing of hospitals by Germans on the Western front, said that a raid was carried out on the night of May 19th-20th against Etaples, where are a large number of hospitals; over 300 casualties were caused to hospital patients. He added that a full report on the subject had not yet been received.

¹ *Deut. med. Woch.*, November 15th, 1917.

Perhaps it may be proper, or at least charitable, to suspend judgement, and not to attach too much importance to the statement of the captain of the Gothia which was brought down, to the effect that hospitals should not be placed near railways, and that if they were the consequences must be taken. The raid began at ten in the evening and lasted nearly three hours. A short interval about 11.30 is held to make it probable that two separate squadrons were employed, numbering between them over a score of machines. The dunes north of the village of Etaples are not exclusively given up to hospitals, but the hospitals occupy a compact area and are close together. It was over this area that the German aeroplanes circled, dropping bombs, setting quarters on fire, and causing many casualties as Mr. Bonar Law stated. The other military establishments in the neighbourhood which might have been legitimate objects of the raiders seem to have escaped, but upon this point no definite information is available. At the same time it must be remembered that strong evidence was advanced last October that the German airmen deliberately engaged in the bombing of advanced hospitals both of the British and French armies on the Western front. The French authorities were absolutely convinced of the truth of this charge, and the story as told by them left little room for doubt.

A MONTHLY REVIEW OF THE FOREIGN MEDICAL PRESS.

ONE of the tasks of the General Staff at the War Office during the war has been the issue of a daily review of the foreign press, the scope of which has been extended from time to time by the preparation of supplements dealing with special subjects. A monthly medical supplement, compiled by the Medical Research Committee, was added to the list in January last, and since then has been widely circulated through official channels for the assistance of naval and military workers, and particularly among the British and American Expeditionary Forces. It has been warmly welcomed by those entitled to receive it, but its usefulness has been limited hitherto by the fact that it has been inaccessible to many medical men to whom it would be of interest. This limitation has now been removed by the decision to place the medical supplement on sale, and the June and subsequent numbers will be obtainable from H.M. Stationery Office, either direct or through any bookseller, at the cost of one shilling.

The Croonian Lecture before the Royal Society will be delivered by Major W. B. Cannon, Professor of Physiology, Harvard, on Thursday, June 20th, at 4.30 p.m., the subject being the physiological basis of thirst.

Medical Notes in Parliament.

Ministry of Pensions.

THE first day of Parliament, when it reassembled on May 28th, was given to a discussion of the administration of the Ministry of Pensions.

The Minister, Mr. Hodge, in his opening statement, said that progress had been made in the organization of the department and that the staff had been largely increased. He took credit to himself for having recognized that the supervision of the work of restoration of disabled pensioners called for expert advice and that he had in consequence started a medical service department; since its staff had been completed the developments had been exceedingly great. Instead of concentrating the orthopaedic treatment in two or three centres the principle of decentralization had been adopted, and it was hoped to have an orthopaedic clinic in all towns, his view being that the more the facilities were brought to the door of the men, the more likely would they be to avail themselves of the opportunities. The Ministry was greatly indebted to many physicians and surgeons for the disinterested voluntary services

they had rendered not only in respect of orthopaedics, but also as regards those diseases which came more under the notice of the physician. Another department had been established for artificial limbs, including an experimental laboratory where all so-called new inventions could be exploited for the benefit of the disabled. The artificial limb makers of the United Kingdom had fallen in with the scheme, and were now prepared to make to the specification of the Ministry any limb which the Advisory Committee decided was the best. In regard to hospital accommodation, the Ministry was dependent upon the assistance of other Government departments. The Ministry was greatly indebted to the British Red Cross, and he regretted to have to differ from it with regard to the use of the Golders Green institution for shell shock cases. Down to the end of April the number of disabled men who had received pensions was 341,025, this number including officers and men of the army, and officers, warrant officers, petty officers, and men of the navy. The percentages of certain injuries were as follows:

Eyesight cases	2.8 per cent.
Wounds and injuries to legs necessitating amputation	2.6 "
Wounds and injuries to arms necessitating amputation	1.4 "
Wounds, etc., to legs not necessitating amputation	11.9 "
Wounds, etc., to arms not necessitating amputation	8.45 "
Wounds, etc., to hands not necessitating amputation	4.45 "
Wounds, etc., to head	4.0 "
Hernia	0.8 "
Miscellaneous wounds and injuries	5.55 "
Chest complaints and tuberculosis	11.6 "
Rheumatism	6.5 "
Heart disease	10.3 "
Epilepsy	1.0 "
Nervous diseases, shell shock, neurasthenia, etc.	6.0 "
Insanity	0.75 "
Deafness	2.0 "
Frostbite, including cases of amputation of feet or legs	0.9 "
Miscellaneous diseases, including Bright's disease, debility, gastric ulcer, varicocele, enteric, malaria, spinal disease, and appendicitis	18.36 "

The Ministry had endeavoured to set an example to other Government departments by employing disabled men, and now had between two and three hundred so employed. The armless men would probably be the greatest difficulty in the future, and out of seventy messengers employed by the Ministry, 55 were one-armed men. Mr. Hodge appealed to public authorities who required messengers to give the preference to one-armed men.

The subsequent discussion, which was interrupted by an attempt to count the House out, turned chiefly upon rates of pension. In his reply Sir A. Griffith-Boscawen again insisted that the amount of a man's pension did not depend upon his earnings; it was fixed simply and solely on the degree of his physical disablement. Medical boards were not authorized to ask a man what he was earning.

Registrars of Military Hospitals.—Major David Davies asked, on May 28th, whether, in order to utilize the services of doctors in the R.A.M.C. to the fullest extent, officers not belonging to the R.A.M.C. declared to be unfit for general service would be appointed as registrars of military hospitals and convalescent establishments. Mr. Macpherson replied that the duties of registrars of military hospitals included those of a purely professional nature, and it was not considered that such posts could be efficiently filled by officers other than those in the R.A.M.C.

ALTHOUGH the date for publication of the new electors' list under the Reform Act has been postponed from June 15th to June 29th, it is understood that every effort is to be made to secure that the Register comes into force on the date originally fixed—October 1st. In a recent debate in the Commons the President of the Local Government Board (Mr. Hayes Fisher) expressed grave doubts whether this could be done; but the word has now gone forth that the Register is to be available on October 1st. To make it at all satisfactory the local authorities will probably have to proceed with house-to-house inquiries in many cases to obtain the necessary information. The life of the present Parliament expires in July, and an extension of its existence by a short bill will again, of course, become necessary.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

TEMPORARY SURGEON A. L. PEARCE GOULD, R.N.

Surgeon Alfred Leslie Pearce Gould, R.N., attached to the Royal Marine Light Infantry, Royal Naval Division, was killed in action on Whit Sunday, May 19th, aged 31. He was the youngest son of Lieut.-Colonel Sir Alfred Pearce Gould, K.C.V.O., R.A.M.C.(T.F.), and was educated at Christ Church, Oxford, where he gained a classical scholarship, and graduated B.A., with first class honours in natural science, in 1909, and M.A., M.B., and B.Ch. in 1913; and at University College Hospital, where he won the Erichsen prize in practical surgery in 1913, and the Atchison scholarship in 1914, taking the M.R.C.S. and L.R.C.P.Lond. in 1913, and subsequently the F.R.C.S. in 1916, and filling the posts of house-physician and obstetric house-physician. He was appointed house-surgeon to Mr. Trotter, but the outbreak of the war prevented his entering upon this post. In 1916 he obtained the higher degrees of M.D. and M.Ch., and in the following year he was elected to a Radcliffe Travelling Fellowship of the University of Oxford. During the war he published several papers on clinical subjects.

The Director-General of the Medical Department R.N. states that Surgeon Pearce Gould's work was greatly appreciated in the navy, and that his loss will be very keenly felt both from the point of view of his professional capabilities and because he was such a cheery messmate.

Temporary Surgeon-General Rolleston, R.N., writes: Since the outbreak of war in August, 1914, when we were messmates at the Royal Naval Hospital, Haslar, I had seen much of Leslie Pearce Gould, and learnt to admire his sterling qualities as a straight, clean English gentleman. His life's motto might well have been, "Whatsoever thy hand findeth to do, do it with thy might," for both his work and play reflected this. Among the first to volunteer as a temporary surgeon on August 3rd, 1914, he had a varied experience; but when, after being invalided from the Mediterranean with enteric, he was established at the Royal Naval Hospital, Plymouth, in a post which gave his surgical talents full scope and opportunities, he soon began to feel that he ought not to have such a job when others were bearing the brunt and dangers of active service at the front. After some delay and consideration he asked to be transferred to the Royal Naval Division on the Western front, though it was pointed out to him that the work he could expect there was hardly likely to be so useful as that he was doing at Plymouth. It was impossible not to honour the motives dictating a step destined, as it turned out, to cut short so lamentably a life of the greatest promise. With a broad outlook on medical science he would have made a real physician, but he had already decided on a surgical career and had laid the surest foundations for the highest kind of success.

Accidentally Injured.

Surgeon Probationer G. R. Falcon, R.N.V.R.

Prisoner of War.

Surgeon H. C. Broadhurst, R.N. (temporary).

ARMY.

Killed in Action.

CAPTAIN ST. J. A. M. TOLHURST, N.Z.M.C.

Captain St. John Alexander Molesworth Tolhurst, New Zealand Medical Corps, was killed in action on May 12th. He was the youngest son of George Edmeades Tolhurst, of the Union Bank of Australia, Wellington, New Zealand, and was educated at the college in that city, and at Guy's Hospital, where he was captain of the Rugby fifteen. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1907, and graduated M.B. and B.S.Lond. in 1909. After acting successively as out-patient officer, house-physician, and assistant house-surgeon at Guy's, he returned to New Zealand, and went into practice at Wellington, where he was honorary physician to the hospital. He joined the New Zealand forces at the beginning of the war, and served in the New Zealand hospital ships *Mahana*, at

Gallipoli, and *Marama*, and afterwards with the 3rd N.Z.F.A., and with the New Zealand infantry. He was killed while working in an aid post.

Died of Wounds.

MAJOR J. B. METCALFE, D.S.O., M.C., A.A.M.C.

Major James Beverley Metcalfe, whose death from wounds we recorded in our issue of May 18th, was the son of the late Dr. Metcalfe of Norfolk Island, and was born on January 13th, 1888. He studied medicine at the University of Sydney, where he graduated with distinction M.B., Ch.M. in 1911. After a year as resident medical officer at the Royal Prince Alfred Hospital, Sydney, he started in private practice in Wellington, N.S.W. He was a great sportsman, and represented his university at football and tennis. Having joined the A.I.F., he proceeded to France early in 1916, and was awarded the M.C. for gallantry in the field in October of the same year, receiving his promotion to the rank of major on January 29th, 1917. After serving as battalion medical officer, and also in a field ambulance, he was appointed D.A.D.M.S. Australian Corps, and while acting in this capacity was wounded near Ypres in October, 1917. He proceeded overseas again at the end of last March, and was in charge of an advanced dressing station on the river Ancre on April 24th. In consequence of heavy shelling the dressing station had to be evacuated, but Major Metcalfe returned to dress a "casual," when two shells exploded, inflicting fatal injuries. For his gallantry on this occasion he received a posthumous award of the D.S.O. Major Metcalfe combined an artistic temperament with sound common sense, and was deservedly popular with his senior officers and the men who worked under him. Brave almost to rashness, he had administrative and professional abilities above the ordinary, and was a good soldier and a gallant gentleman.

CAPTAIN D. H. HALL, R.A.M.C.

Captain David Henry Hall, R.A.M.C., was reported as having died of wounds, in the casualty list published on May 24th. He was educated at Trinity College, Dublin, where he graduated M.B. and B.Ch. in 1915, after which he took a temporary commission in the R.A.M.C., and was promoted to captain after a year's service. He was attached to the Seaforth Highlanders.

Died on Service.

DR. R. W. SPENCE.

Dr. Reginald Westmore Spence died of blood poisoning, on service in East Africa, on May 19th, aged 31. He was the eldest son of Mr. Ernest Spence of Guildford, and was educated at Westminster Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1913.

Wounded.

Lieut.-Colonel D. Aherne, D.S.O., R.A.M.C.

Lieut.-Colonel W. H. Burney, R.A.M.C.

Major N. W. Kidston, R.A.M.C.(T.F.).

Captain R. J. Aherne, R.A.M.C. (temporary).

Captain L. H. H. Boys, R.A.M.C. (temporary).

Captain A. Buchanan, R.A.M.C. (temporary).

Captain H. E. Cresswell, M.C., R.A.M.C. (temporary).

Captain F. R. M. Higgs, R.A.M.C.(T.F.).

Captain H. Mendelssohn, Australian A.M.C.

Captain W. H. Morrison, R.A.M.C. (T.F.).

Lieutenant T. W. Shaw, R.A.M.C. (temporary).

Prisoners of War.

Captain J. B. Ball, R.A.M.C. (temporary).

Captain S. J. Darke, M.C., R.A.M.C. (temporary).

Captain W. J. Isbister, M.C., R.A.M.C. (temporary).

Captain S. V. P. Pill, R.A.M.C. (temporary).

Captain J. R. H. Ross, M.C., R.A.M.C. (temporary).

Captain J. Sullivan, R.A.M.C. (temporary).

Lieutenant E. M. P. Maitland, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Blurton, Gril Evers, Second Lieutenant Sherwood Foresters, younger son of Dr. Blurton, West Bridgford, Nottingham, reported missing on October 22nd, 1917, now known to have been killed in action on that date, aged 20. He was educated at Sedburgh School and Sandhurst, obtained his commission in October, 1916, and went to France in December of that year. He had previously been wounded.

Clare, Horace Townsend, Captain Royal Field Artillery, youngest son of Dr. Henry L. Clare, late Surgeon-General,

Trinidad, killed April 29th, aged 21. He was educated at Haileybury, entered Woolwich in 1913, and got his first commission on November 17th, 1914. He served in Gallipoli, in the 29th Division, till the evacuation, was mentioned in dispatches, and promoted to lieutenant in the R.H.A. He afterwards served in Egypt and in France, and took part in the long battle on the Somme in 1916, after which he was invalided. He returned to France in June, 1917, was wounded at Monchy-le-Preux, but returned to duty in October; was promoted to captain R.H.A. on November 1st, 1917, and to acting major R.F.A. on March 29th, 1918.

Dodgson, Edward Hughes, younger son of the late Dr. Dodgson of Cockermouth, died of wounds at a casualty clearing station on May 3rd.

Mitchell, E. P. H., Second Lieutenant Border Regiment, only son of Dr. Mitchell of Ambleside, was accidentally killed while flying abroad on May 7th, aged 20. He was attached to the Royal Air Force as instructor in aviation.

Swift, Neville Copley, M.C., D.S.O., Captain East Lancashire Regiment, youngest son of Dr. H. Swift, senior physician to the Adelaide Hospital, South Australia, died of wounds on March 28th, aged 23. He was educated at St. Peter's College, Adelaide, and served two years in the Australian militia, rising to the rank of lieutenant. He came to England in 1915, and, after a course of instruction at Sandhurst, obtained a commission in the East Lancashire Regiment. He was wounded in France in August, 1916, and again in 1917, and was awarded the Military Cross in December, 1917, when in command of a company with the rank of captain. In January, 1918, he gained a bar to the Military Cross while acting as major and second in command of a battalion, and was recommended for the D.S.O. He was wounded on March 27th while leading his battalion in a counter attack, and died the next day in hospital.

Wilkinson, Arthur W., Captain West Yorkshire Regiment, second surviving son of Dr. Wilkinson of Tynemouth, died from wounds received in action on April 18th. He was born in 1884, educated at Epsom College, and was practising as an architect in 1914 when the war broke out. He obtained a commission in the 9th Durham Light Infantry in 1908, but transferred in 1915 to the special reserves of the West Yorkshire. On July 1st, 1916, he was shot through the right lung, but recovered, and returned to France in 1917.

MEDICAL STUDENT.

Allardyce, George Gilmour, Second Lieutenant Australian Infantry, eldest son of Mr. George Allardyce of Rathgar, Dublin, died on May 18th at Somerville Hospital, Oxford. He was a second-year medical student at Trinity College, Dublin. His younger brother, William Swirls Allardyce, was lost at sea in December, 1916, as the result of a collision, while serving as a surgeon probationer.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

MENTIONED IN DISPATCHES.

THE following officers of the medical services are mentioned by Sir Douglas Haig in his dispatch dated April 7th, 1918, for distinguished and gallant services and devotion to duty between September 25th, 1917, and February 25th, 1918:

ARMY MEDICAL SERVICE.

Head Quarters Staff.

Lieut.-General Sir A. T. Sloggett, K.C.B., K.C.M.G., K.C.V.O. Major-Generals: C. H. Burchaell, C.B., C.M.G., Sir W. G. Macpherson, C.B., K.C.M.G., H. N. Thompson, C.B., C.M.G., D.S.O.

Surgeon-General M. W. O'Keefe, C.B. Colonel (temporary Surgeon-General) B. M. Skinner, C.B., C.M.G., M.V.O.

Colonels: H. A. Bray, C.M.G., R. W. Clements, D.S.O., W. E. Hudleston, D.S.O., Sir W. B. Leishman, C.B., F.R.S., S. Macdonald, C.B., C.M.G., F. J. Morgan, C.M.G., D. M. O'Callaghan, C.M.G., G. St. C. Thom, C.M.G.

Lieut.-Colonels (temporary Colonels): H. Collinson, D.S.O., R. S. H. Fuhr, C.M.G., D.S.O., J. S. Gallie, D.S.O., J. Grech, D.S.O., L. Humphry, C.M.G., E. M. Morpew, D.S.O., G. J. A. Ormsby, D.S.O., A. G. Thompson, D.S.O.

Lieut.-Colonels and Brevet Colonels: T. W. Gibbard, K.H.S. (temporary Colonel), A. J. Macnab, I.M.S.

Lieut.-Colonels: W. R. Blackwell, T. A. Granger, I.M.S., H. C. R. Hime, D.S.O., J. F. Martin, C.M.G.

Major (temporary Colonel) C. H. Lindsay, C.M.G. Majors (temporary Lieut.-Colonels): E. T. Potts, D.S.O., D. P. Watson.

Major (acting Lieut.-Colonel) P. Davidson, C.M.G., D.S.O. Majors: R. B. Black, D.S.O. (R. of O.), A. C. Turner.

Captains: L. G. Bourdillon, D.S.O., M.C., A. D. Child, (S.R.), K. K. Drury, M.C. (S.R.), T. I. Dunn, M.C. (S.R.), A. H. Heslop, D.S.O., J. G. McCutcheon, (S.R.), O. W. D. Steel, M.C., L. R. Tosswill.

Temporary Captains: J. Biggam, M. du B. Ferguson, R. E. Gibson, S. S. Greaves, M.C., H. G. Kilner, G. Rankine, M.C., R. H. G. Weston.

Consultants.

Temporary Major-Generals: Sir A. A. Bowlby, K.C.M.G., K.C.V.O., Sir J. R. Bradford, C.B., K.C.M.G., F.R.S., Sir B. E. Dawson, C.B., G.C.V.O., C. S. Wallace, O.M.G. Colonel E. M. Pilcher, D.S.O.

Temporary Colonels: O. W. Richards, D.S.O., T. Sinclair, C.B., Sir A. E. Wright, C.B., F.R.S.

Lieut.-Colonel (temporary Colonel) W. Thorburn, C.B. Majors (temporary Colonels): G. E. Gask, D.S.O., H. Mol. W. Gray, C.B.

Major (temporary Lieut.-Colonel) H. A. Ballance.

Major R. H. Cooper.

Captain (temporary Colonel) A. E. Webb-Johnson, D.S.O.

Captain (temporary Lieut.-Colonel) A. E. Watson, D.S.O.

Royal Army Medical Corps.

Lieut.-Colonel (temporary Colonel) J. A. Hartigan, D.S.O.

Lieut.-Colonels: A. E. Hamerton, D.S.O., J. Powell.

Temporary Lieut.-Colonels: O. G. Douglas, M.C., W. J. E. Eames, C.B., V.D. (Lieut.-Colonel A.A.M.C.), A. Martin-Leake, V.C., Guy N. Stephen.

Temporary honorary Lieut.-Colonel H. Cabot.

Majors (temporary Lieut.-Colonels): R. C. Hallows, T. E. Harty, D.S.O., W. J. S. Harvey, D.S.O., A. C. Osburn, D.S.O.

Majors (acting Lieut.-Colonels): O. G. Browne, D.S.O., J. Dalrymple, G. D. Gray, R. P. Lewis, C. D. Myles, H. O. Sidgwick, W. L. Steele, C. H. Turner, D.S.O., T. B. Unwin, W. J. Waters.

Majors: T. S. Coates, R. H. Cooper, J. E. Hoar, J. L. London, M. Sinclair.

Temporary honorary Major L. F. B. Knuthsen.

Captain (temporary Lieut.-Colonel) F. W. M. Cunningham.

Captains (acting Lieut.-Colonels): W. W. Boyce, C. Clarke, R. Hemphill, A. N. R. McNeill, T. B. Nicholls, J. J. O'Keefe, M.C., C. Scaife, E. W. Wade.

Captains: W. P. Mulligan, W. G. Mumford, E. Phillips, M.C., W. L. Webster.

Temporary Captain (temporary Lieut.-Colonel) O. D. Pye-Smith, D.S.O., M.C.

Temporary Captains (acting Lieut.-Colonels): R. E. Drake-Brockman, A. Jones, M.C., L. D. Shaw, D.S.O.

Temporary Captains: J. Alexander, A. S. K. Anderson, D.S.O., M.C., J. S. Arkle, C. C. Ansten, T. B. Batchelor, W. O. Blackham, A. D. Blakeley, C. F. Brady, G. M. Brown, J. P. Cahir, S. B. B. Campbell, T. H. Campbell, H. Caplan, F. E. Carr-Harris, D.S.O., M. T. Cassidy, A. W. S. Christie, C. J. W. Clayton, C. G. Colyer, J. A. Conway, M.C., G. M. Cowper, W. Crabtree, J. Crawford, J. Cruickshank, G. D. Eccles, J. A. Edmond, H. Emerson, M.C., C. C. Forsyth, D. S. Graham, H. B. Graham, D.S.O., A. Gray, C. Harris, F. W. Hird, L. C. Johnson, W. D. Kennedy, P. J. Lane, R. M. Lang, R. D. Lemon, G. A. Lilly, S. J. L. Lindeman, W. H. Lister, D.S.O., M.C., A. L. Lockwood, M.C., P. A. MacCallum, S. E. McClatchey, J. W. Macfarlane, M.C., R. McGrath, R. A. MacNeill, A. O. B. MacMurtrie, W. R. P. McNeill, A. F. Mavety, D. M. Morison, J. Morrison, H. H. P. Morton, G. E. E. Nicholls, F. E. L. Phillips, J. G. Pigott, J. A. Pringle, J. Proctor, C. R. Reckitt, W. G. Riddell, A. C. Rowse, C. Scales, D. S. Taylor, G. W. Twigg, W. Warburton, W. W. Wells, C. R. Whittaker, D. R. Williams, R. L. Williams, M.C.

Temporary honorary Captain H. Nockolds.

Lieutenant (temporary Captain) G. R. Dudgeon, M.C.

Temporary Lieutenant J. S. Clark.

Quartermasters and honorary Majors: H. J. F. Audus, E. J. Buckley, J. Greco.

Quartermasters and honorary Captains: F. C. Cross, C. A. Figg, (acting Major) J. T. Packard, E. B. Senior, F. Wilson.

Temporary Quartermasters and honorary Captains: B. G. Brook, T. W. Jent.

Quartermaster and temporary Lieutenant V. A. Bell.

Quartermasters and honorary Lieutenants: H. B. Lee, H. Steele.

Temporary Quartermasters and honorary Lieutenants: E. Kerstein, M.C., P. le Poidevin, J. B. Mackay, H. Miller, E. B. Snowden.

Royal Army Medical Corps (S.R.).

Captains (acting Lieut.-Colonels): C. J. A. Griffin, S. Miller, M.C., K. D. Murchison, D.S.O., A. T. Pitts, R. T. C. Robertson, D.S.O.

Captains: W. R. Blore, C. F. Burton, W. B. Cathcart, E. M. Cowell, T. G. Fleming, F. H. Goss, R. A. Greenwood, T. F. Hegarty, F. Jefferson, J. I. Lawson, W. McK. H. McCullagh, D.S.O., M.C., G. H. C. Mold, C. M. Page, H. G. Trayer.

Royal Army Medical Corps (T.F.).

Lieut.-Colonel W. E. Foggie.

Majors (temporary Lieut.-Colonels): E. B. Bird, D.S.O., J. Nightingale, C. A. A. Stidson, D.S.O., W. G. Sutcliffe, P. G. Williamson, M.C.

Major (acting Lieut.-Colonel) A. Callam.

Major T. A. Barron.

Captain and Brevet Major (temporary Lieut.-Colonel) O. H. S. Frankan.

Captains (temporary Lieut.-Colonels): J. Bruce, C. W. Eames, Captains (acting Lieut.-Colonels): W. Blackwood, F. G. Dobson, C. L. Lander, M.C., H. B. Low, M.C., G. Mackie, D.S.O., J. MacMillan, M.C., A. J. Williamson.

Captain (temporary Major) E. Knight.

Captains: J. W. Anderson, M.C., C. F. Backhouse, F. G. Caley, O. Cattlin, J. W. Dale, H. N. Goode, J. H. Hamill, T. R. Kenworthy, G. O. King, G. H. Kirby, S. A. S. Malkin, A. O.

Mallace, R. P. Pollard, H. H. Robinson, M.C., F. E. W. Rogers, S. Scott, J. M. Smith, W. Stobie, A. C. Watkin.

Temporary Captain L. Blake.

Quartermaster and honorary Captain C. W. Braithwaite.

Quartermaster and honorary Lieutenant T. Priest.

CANADIAN FORCES.

Staff.

Colonels: H. A. Bruce, C.A.M.C.; H. M. Jacques, D.S.O., C.A.M.C.; A. E. Ross, D.S.O., C.A.M.C.; R. P. Wright, D.S.O., C.A.M.C.

Major (temporary Lieut.-Colonel) A. E. Snell, D.S.O., C.A.M.C.

Majors: G. H. R. Gibson, C.A.M.C.; G. G. Greer, M.C., C.A.M.C., T. A. Loner, C.A.M.C.

Canadian Army Medical Corps.

Colonel J. M. Elder.

Lieut.-Colonels: G. J. Boyce, D. Donald, A. S. Donaldson, A. L. C. Gilday, J. A. Gunn, J. Hayes, D. P. Kappeler, A. C. Rankin, S. J. Stewart.

Temporary Lieut.-Colonel J. N. Gunn.

Major (acting Lieut.-Colonel) H. H. Moshier.

Majors: A. W. M. Ellis, G. S. Mothersill, D.S.O., G. S. Strathy.

Temporary Major (acting Lieut.-Colonel) E. R. Selby.

Captains: J. E. Barry, H. McL. Cameron, W. A. Richardson, S. J. Streight, W. C. Walsh, H. W. Whytock.

Temporary Captains: F. R. Hassard, M.C., H. G. Young, D.S.O.

Quartermaster and honorary Captains: J. E. Lawrence, J. E. Tulloch.

AUSTRALIAN IMPERIAL FORCE.

Staff.

Colonel R. B. Huxtable, D.S.O., V.D., A.A.M.C.

Lieut.-Colonels (temporary Colonels): F. A. Maguire, A.A.M.C., A. E. Shepherd, A.A.M.C.

Majors: W. J. W. Close, A.A.M.C., D. M. Embleton, A.A.M.C., W. J. Stack, A.A.M.C., W. Vickers, A.A.M.C.

Australian Army Medical Corps.

Lieut.-Colonels: E. T. Brennan, M.C., T. P. Dunhill, W. E. Kay, B. Quick, H. C. Taylor-Young, W. G. D. Upjohn.

Majors (temporary Lieut.-Colonels): A. F. Maclure, V. O. Stacy.

Majors: F. L. Bignell, E. A. Brummitt, A. L. Buchanan, A. R. Clayton, A. T. Dunlop, T. C. C. Evans, E. L. Hutchinson, D.S.O., F. N. le Messurier, D. S. Mackenzie, A. McKillop, P. A. Maplestone, D.S.O., A. V. Meehan, W. A. Morton, R. J. Taylor.

Captain (temporary Lieut.-Colonel) W. H. Collins, D.S.O.

Captains: R. D. Bartram, G. V. Davies, D.S.O., A. J. McK. Fergie, R. P. W. Francis, J. C. M. Harper, M. J. Holmes, A. J. de S. Howard, J. A. Love, R. G. McPhee, C. M. Samson.

Honorary Captain P. Smith.

Quartermasters and honorary Captains: J. A. Anderson, H. Hazlett, R. C. Rutter.

NEW ZEALAND MEDICAL CORPS.

Lieut.-Colonel E. J. O'Neill, D.S.O.

Majors: H. M. Buchanan, E. L. Marchant, E. A. Widdowson.

Captains: T. W. J. Childs, J. Mitchell.

SOUTH AFRICAN MEDICAL CORPS.

Lieut.-Colonel G. R. Thomson.

Major C. M. Murray.

Captain H. R. Lawrence.

INDIAN MEDICAL SERVICE.

Lieut.-Colonel J. B. Jameson.

Major (temporary Lieut.-Colonel) E. O. Hodgson.

Majors: D. H. F. Cowin, E. A. C. Matthews.

AMERICAN MEDICAL CORPS.

Temporary honorary Major V. H. Kazanjian (Harvard General Hospital).

The list also includes a large number of warrant and non-commissioned officers and privates of the R.A.M.C. and of the Colonial medical services, together with numerous members of the nursing services.

Scotland.

THE SCOTTISH CHURCHES AND VENEREAL DISEASE.

ON May 23rd Dr. David Newman of Glasgow addressed a meeting of ministers of the Church of Scotland and the United Free Church on the subject of venereal disease. He said that the reasons why venereal disease demanded attention specially at the present time were: (1) That marked progress had been made in recent years in combating the ravages of the disease by exact diagnosis and effective treatment; (2) now that the report of the Royal Commission was in the hands of the public it was recognized by all who had a knowledge of the subject that it was high time that the whole question was pushed forward and a determined attempt made to control one of the greatest scourges that affect mankind; (3) in the past it had been a constant experience that after all wars there was a formidable increase in venereal disease. In Glasgow a local centre of the National Council for Combating Venereal Disease had been formed, and was carrying on active work. Attention was called by Dr. Newman to the immediate and remote effects of these diseases. If public opinion was not on the alert to use every measure to combat the evil, it would become a danger as great as the war itself. The question of prevention was mixed up with that of prompt and effective treatment. A clear and carefully considered scheme of instruction must be arranged—one for girls, another for boys—in regard to sex teaching and personal hygiene. The value of games and the occupation of the mind on healthy subjects was dwelt upon. From the moral aspect many men were faint-hearted, saying the disease was a necessary evil, and that it was impossible to put a stop to immorality. But the word impossible had been deleted from the vocabulary of medicine and surgery. Could not the Church do the same? Since the report of the Royal Commission was published many leaders in the Church had joined the National Council for Combating Venereal Disease, and had taken an active part in promoting its objects, but the great body of the clergy had not had the facts brought before them. While it was clearly the duty of the doctor to cure and prevent disease it was equally the duty of the Church to face the question with courage, and aid in lifting the whole subject to a higher sphere by purifying the thoughts of the rising generation. The medical profession was warring against the disease; the Church had to teach that unchastity was a serious sin in itself, quite apart from the danger of contracting disease, and passing it on as a hateful gift to the next generation.

DR. ELSIE INGLIS.

At the Royal Scottish Academy, Edinburgh, on May 27th, under the presidency of the Lord Provost, Prince George of Serbia formally presented to the Scottish nation a bust of the late Dr. Elsie Inglis, the work of Mestrovic, the Serbian sculptor. In accepting the gift, Mr. R. Munro, Secretary for Scotland, eulogized Dr. Inglis's noble work in Serbia. The bust is executed in bronze, and is considered both an excellent likeness and an admirable work of art. M. Yovanovich, Minister Plenipotentiary for Serbia, spoke of the great work accomplished by the Scottish Women's Hospitals, of which Dr. Elsie Inglis was the moving spirit, and expressed the gratitude and admiration felt by the Serbian people towards the women of Scotland.

England and Wales.

WARD FOR DISABLED PENSIONERS.

A PENSIONERS' ward at the David Lewis Northern Hospital, Liverpool, was formally opened by Colonel Sir Robert Jones, C.B., F.R.C.S., on May 25th. The ward contains twenty-eight beds, to be devoted entirely to pensioners requiring special treatment. The main object is to restore disabled soldiers so as to enable them to earn their own livelihood, and as far as possible resume their former civil occupation. An out-patient department is to be developed for electrical treatment and remedial exercises. This undertaking by the Northern Hospital will relieve the congestion of the Alder

M. BILDT, Swiss Minister at Rome, recently gave £2,000 to the Italian Red Cross. The Minister of Siam gave £200.

THE French Government has established sanatoriums, each with two hundred beds, in all colonies of the French West Africa group (Senegal, Upper Senegal and Niger, Guinea, Côte d'Ivoire, Dahomey and Gaboon). These institutions are intended primarily for the reception and gratuitous treatment of sick native soldiers from the French armies, especially those suffering from curable tuberculosis. A dispensary for consultations and for gratuitous home treatment is to be established in the most important centres of the West African colonies and French Equatorial Africa.

Hey and Highfield hospitals, where the recent cases requiring orthopaedic treatment are received. Sir Robert Jones aptly remarked that a crippled soldier discharged too soon from the hospital became a "focus of discontent." The aim of the present undertaking was, he said, to prevent such a misfortune by carrying out further treatment to enable the patient to become fit for re-employment and once more independent. Such measures were imperatively required, and he felt proud that Liverpool was among the first cities to found such an institution for disabled soldiers.

Correspondence.

ADAPTATION AND DISEASE.

SIR,—In July last year a controversial correspondence between Dr. J. G. Adami and Sir Ray Lankester was published in your periodical. I heard something of it at the time, but recently Dr. Adami has published his Croonian lectures on adaptation and disease, with other matter, in book form, and has reprinted the correspondence as an appendix in the volume. This correspondence originated in a severe criticism by Sir Ray Lankester of the substance of Dr. Adami's lectures, and of the manner in which the subject was treated. The volume has recently come into my hands, and as one who has taken some part in the investigation and discussion of adaptation and its evolution, I desire to make some comments on the arguments of both the medical and the zoological writers.

Dr. Adami uses the term "academic" in an unusual sense, and applies it with an unfavourable meaning to men who have made important original contributions to science. Academic does not, as generally used, mean "more concerned with tradition than discovery," but simply the pursuit of pure knowledge as distinct from its practical application. The medical man who investigates the action of different conditions upon bacteria is quite as academic as he who studies the development of a starfish; the former only ceases to be academic when he applies his discoveries in a particular treatment of disease. Sir Ray Lankester is well known to have shown himself a brilliant and original morphologist, who in his time has dislodged a good many traditions. He has not, however, concerned himself with the investigation of evolutionary problems, and in this branch of biology is perhaps open to the charge of retaining too great a respect for tradition, in particular the Darwinian tradition. It is rather difficult to understand definitely what view Sir Ray takes with regard to the influence of external conditions. He states that he has always maintained that "specific variation" may be induced by external influences. If a specific variation is due to external causes—and it can scarcely be specific unless it is hereditary—it follows that Sir Ray has always maintained that acquired characters may be transmitted by heredity. Yet the last paragraph of his first letter states that it is widely admitted that no case of such transmission has been demonstrated, and seems to imply that he agrees with Weismann that acquired characters are not inherited. Discussion, however, of evolutionary phenomena under the general terms of specific variation and acquired characters belongs to a bygone period. At the present day we require physiological details and concrete examples.

With the general tendency of Dr. Adami's views I am in agreement. His criticism of Bateson's extraordinary theory that no new characters have ever arisen, but that all possible characters were originally contained in the protoplasm of the primordial ancestral forms is perfectly sound, but that does not justify him in descending to ridicule. A great part of Dr. Adami's argument is concerned with specific changes produced in bacteria by conditions of life, but that does not in the least bear on the question how modifications of the somatic tissues in the higher animals can be inherited by the offspring. With this latter question Dr. Adami deals, but he gets no farther than the conclusion that influences from without affecting the organs of internal secretion may through their hormones influence the germ cells, so that acquired metabolic disturbances are inherited. How does this help us to understand the evolution of the horse's foot or the bat's wing? Dr. Adami has the audacity to claim priority

with respect to the publication of a hormone theory of heredity, and to place my name in a footnote, together with those of Heape, Bourne, MacBride, and Dendy, no one of whom, I believe, had published anything of importance on the subject prior to 1908, when my own theory was first printed. According to this note we have "since enunciated" the conclusions reached by Dr. Adami in 1901. He reprints in this volume the paper to which he refers, from the *New York Medical Journal* and *BRITISH MEDICAL JOURNAL* of that year. The relevant part of this paper is under three headings in the latter portion of it: (1) The non inheritance of acquired mutilations. This need not detain us, as it is negative. (2) The indirect transmission of acquired diathesis. The local lesion is not inherited, but the disease may lead to altered condition of the blood, which may affect the germ cells and so influence the offspring. This, as further explained in the paper, is not inheritance in the morphological sense at all, but simply poisoning of the germ cells. (3) The direct transmission of acquired constitutional states. The examples given are occasional inheritance of acquired immunity, and greater susceptibility to a disease in the offspring of parents who have suffered from the disease. None of these conclusions throw any light on the problem of the evolution of structural adaptation by the inheritance of somatic modifications. My theory of the evolution of secondary sexual and adaptive characters by the inheritance of somatic modifications was published in the *Archiv für Entwicklungsmechanik* in 1908, and was based on the discoveries of the physiologists concerning the action of hormones. It certainly owed nothing to the vague medical generalities of Dr. Adami.

With regard to the other zoologists considered by Dr. Adami worthy with myself of mention in a footnote, and there accused by him of ignoring his claim to priority, my knowledge of their relation to the doctrine of chemical action in heredity is as follows: Of Heape's share in the matter at the present moment I know nothing. Bourne expounded the idea in an address to the British Association some time later than 1908, and, when challenged on the subject honourably acknowledged my claim to priority in a letter to *Nature*. Dendy put forward the theory in very general terms in his book on *Evolutionary Biology* in 1912, four years after the publication of my paper. The case of MacBride is the most remarkable. In his *Embryology of the Invertebrates* (1914) he referred to hormones or internal secretions as the probable agents by which somatic changes could affect the reproductive cells, and attributed the suggestion to Professor Langley. When I informed him that I had published a detailed theory on the subject in 1908, his reply was that he had not been aware of my prior publication. This reply was the more remarkable because Professor Langley had published nothing on the subject, but had merely conveyed his views to MacBride in conversation.—I am, etc.,

J. T. CUNNINGHAM.

London Hospital Medical College, May 9th.

THE FORMATION OF SEQUESTRA.

SIR,—I have recently made a study of sequestra from the purely radiological standpoint, and believe that I have often seen split-off fragments of bone throw out a fringe of callus and live to be reunited to the parent bone. I found it difficult to understand why some of these detached fragments should live and others die. It seemed evident that neither persistence of blood supply nor adherence of periosteum was a valid explanation, and in an article awaiting publication in the *Archives of Radiology* I have suggested that those fragments die which are exposed directly to bacterial toxins, while others escape by being shut off from the septic area by other tissues. Sir Kenneth Goadby's article (*BRITISH MEDICAL JOURNAL*, May 25th, p. 581) confirms the first part of this surmise, but I am surprised at his statement that "bone fragments split off at the original injury invariably become sequestra."—I am, etc.,

Newcastle-on-Tyne, May 25th.

T. L. BUNTING.

REMOVAL OF FILARIA LOA FROM THE EYE.

SIR,—It may interest readers to know that five years ago a man suddenly appeared before me late at night and abruptly asked, "Can you cut out a worm from my eye?" Having said "Yes," I was told it was a filaria, probably

female, as he felt another in his body, and that he had had one before some years back, having got this one in the Argentine.

I put him close under the electric light and saw distinctly the wriggling form of the worm working towards the inner side under the translucent pink of the eyelid. I caught the tail up together with the skin with a pair of "bull-dog" forceps. The worm in its struggles straightened out, enabling me to cut down upon its head, which I seized with another pair of forceps, and, releasing the first pair, wound the worm out complete by twisting the front part round the forceps. Dr. Harford, of Livingstone College, Leyton (where I then lived) confirmed the man's opinion that it was a female *lar*.

I have the worm and should be pleased to let any one skilled in the life-history of these creatures inspect it.—I am, etc.,

HARDING H. TOMKINS, M.R.C.S.

Parkfield, South Ealing Road,
Ealing, W 5, May 25th.

FAMILY HISTORY IN LINGUAL CANCER.

SIR,—I am interested in the subject of cancer of the tongue and am anxious to ascertain whether there is a family predisposition to the disease, such as occurs in some other forms of cancer.

Will any of your readers kindly tell me whether they know, at first hand, of (a) cancer of the tongue occurring in more than one member of the same generation of a family, (b) in successive generations of the same family—that is, father and son, (c) whether in the rarer case of lingual cancer in women the disease has occurred in families with a markedly cancerous history.—I am, etc.,

London, W., May 25th.

D'ARCY POWER.

EXCISION OF WOUNDS AND FLAIL LIMBS.

SIR,—It is time a note of warning was sounded as to the excessive excision of the wounds in compound fractures. Several cases have lately come to this hospital with flail legs and arms from undue removal of bone fragments. Where more than two inches of femur have been excised firm union seems improbable. The end results of these are likely to be less satisfactory than of cases with extensive comminution, some sepsis (controlled by Carrel-Dakin treatment), and sequestrotomy of necrosed fragments at a late period. Doubtless many of the wound excisions prevent dangerous sepsis and save limbs and lives. It is the happy medium for which I plead.—I am, etc.,

A. NEVE, F.R.C.S.E.,

War Hospital, Dartford, May 27th.

Major R.A.M.C.

A MINISTRY OF HEALTH.

SIR,—The scheme of the British Medical Association's pamphlet assumes naturally that the doctor knows that his duty is to cure a patient as soon as possible and to persuade a patient to carry out his instructions. The accusation that the scheme of the Association is humdrum and unimaginative might with greater aptness be applied to Dr. Veale's ideal of state control. As to voluntary hospitals, one would have thought that the results of state control, as seen during the present war, would have sufficed to prove how unsatisfactory it is in its practical working. I for one should be indeed sorry to see our voluntary hospitals handed over to the care of the state. State control could not shorten the waiting list. Your space is precious, otherwise I should have liked to have dealt with Dr. Veale's contentions in detail. Fortunately, we are not all so melancholy as your correspondent.—I am, etc.,

Bedford, May 25th.

S. J. ROSS.

The Services.

TERRITORIAL DECORATION.

THE Territorial Decoration has been conferred upon the following members of the R.A.M.C.(T.): Lieut.-Colonels W. A. Benson, J. P. Bush, C.M.G., W. K. Clayton, T. Frankish, A. M. McIntosh, J. Oldfield; Majors A. Butler, R. Emmett, F. L. Fennell, A. Fowler, C. W. Miller, D.S.O.; Quartermaster and honorary Major J. Dunn; Quartermaster and honorary Captain A. J. H. Knights.

Obituary.

LIEUT.-COLONEL JAMES FORBES BEATTIE, R.A.M.C.(ret.), died at Inverness, Aberdeenshire, on March 27th, aged 76. He was educated at King's College, Aberdeen; he graduated M.A. in 1860 and M.D. and C.M. of Aberdeen University in 1863; he entered the army as assistant surgeon on September 30th, 1863, and retired as brigade-surgeon-lieutenant-colonel on May 21st, 1890. He served in the Ashanti war of 1873-74 (medal); in the Afghan war of 1878-80, where he took part in the defence of Kandahar (medal and clasp); and in the Egyptian war of 1882, when he was present at the battle of Tel-el-Kebir (medal and clasp and Khedive's bronze star).

SURGEON-MAJOR EDWARD LOUIS MCSHEEHY, R.A.M.C. (retired), died at Wimbledon on May 1st, aged 84. He was educated at Queen's College, Cork, and at the R.C.S.I. Medical School in Dublin, and took the M.D. of the Queen's University of Ireland in 1856, and the L.R.C.S.I. in the same year, and subsequently the M.Ch. in 1866 and the F.R.C.S.I. in 1867. He entered the army as assistant surgeon on May 27th, 1857, became surgeon on May 27th, 1869, and surgeon-major on March 1st, 1873, retiring on May 28th, 1877. He served in the second China war of 1860, receiving the medal, and was a J.P. for the county of Surrey.

Medical News.

THE Medical Defence Union announces in our advertisement columns this week that an agreement has been entered into with the Yorkshire Insurance Company, whereby for an annual premium of 7s. 6d. an indemnity insurance can be effected for £2,500 against legal costs and damages in adverse actions at law in which the defence has been undertaken by the Union.

AT the annual meeting of the Kent Branch of the British Medical Association, to be held on Wednesday, June 12th, at 3.30 p.m., at the Technical Institute, Tonbridge, the president, Dr. Claude Wilson, will give an address on the significance of cardiac murmurs.

AS a recognition of the long service of Lieut.-Colonel Charles Brook, late R.A.M.C.(T.F.), the General Officer Commanding-in-Chief has been pleased to appoint him honorary consulting surgeon to the 4th Northern General Hospital, Lincoln.

A FAIR in aid of the Elizabeth Garrett-Anderson Memorial will be held at the London (Royal Free Hospital) School of Medicine for Women, 8, Hunter Street, W.C.1, on Saturday, June 8th, from noon to 9 p.m.; admission 1s.

THE late Dr. Henry Maudsley left £60,718 net.

DR. W. C. BURNS of Raasay has been appointed a Justice of the Peace for Inverness-shire.

THE Royal Dental Hospital, Leicester Square, has received an additional donation of £100 from the Worshipful Company of Grocers.

DR. AND MRS. HENRY MATURIN of Hartley Wintney, Hants, recently celebrated their golden wedding, and were the recipients of a public presentation.

A DISCUSSION on disinfection in public health work will be opened by Dr. W. G. Savage, M.O.H. Somerset County Council, at a meeting of the Royal Sanitary Institute at Taunton on Friday, June 14th, at 11 a.m.

MISS EDITH HELEN BARRETT, O.B.E., M.B., honorary secretary of the Australian Branch of the British Red Cross Society, has been appointed a Commander of the Order of the British Empire.

PROFESSOR UHLENHUTH has come to the conclusion that under favourable conditions the *Spirochaeta icterogenes* may multiply in water and other media outside its human host.

THE Council of the Carnegie Foundation, at a meeting recently held in Rome, decided to give £4,000 towards the erection of a sanatorium for tuberculous Italian soldiers.

THE Local Government Board has issued a revised edition of the list of sanatoriums and other residential institutions (H.M. Stationery Office; price 1d.) approved by the Board under the National Insurance Act, 1911, for the treatment of persons suffering from tuberculosis, and resident in England, excluding Monmouthshire.

THE General Officer Commander-in-Chief of the French Forces in Italy mentioned H.R.H. the Duchess Elena d'Aosta (née Princess Hélène Louise Henriette de France) in the Order of the Day, and decorated her with the War Medal in recognition of her work with the Italian Red Cross and the active assistance she has given to medical units of the French army in Italy.

PROFESSOR J. G. ADAMI, F.R.S., M.D., and Dr. Amand Routh will speak on the subject of antenatal and neonatal factors in infant mortality at the conference to be held at the Central Hall, Westminster, on July 2nd and 3rd, during National Baby Week. Dr. Truby King, C.M.G., who will lecture on the hygiene of infancy, has undertaken the section dealing with infant physiology and comparison with baby plants and animals at the Educational Exhibition to be held from July 1st to 6th. Mrs. H. B. Irving and the St. Pancras School for Mothers will exhibit a model infant welfare centre; Dr. Eric Pritchard and the St. Marylebone Health Society will give instructions in infant feeding; the Midwives Institute has undertaken a section dealing with the expectant mother; the Association of Infant Welfare and Maternity Centres will demonstrate mothercraft; and Dr. H. C. Cameron will assist in the section devoted to diseases of infancy.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR OF THE BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS NOTES, ETC.

TREATMENT OF MENINGITIS.

CAPTAIN H. M. CADE, R.A.M.C., officer in charge Cerebro-spinal Fever Laboratory, Ipswich, writes with reference to the treatment of meningitis as follows: I have seen many cases occurring in children and young soldiers where the characteristic clinical signs of meningitis have been present, where on lumbar puncture a clear fluid, increased in quantity and tension, has been procured, but where the fluid on examination has proved to be of normal character. May not Mrs. Fysh's three cases of recovery been of this type, that is, not cases of meningitis at all?

My excuse for taking up valuable space is to point out the great value of early lumbar puncture in all cases of, or suspected cases of, meningitis. By adopting this procedure not only will the diagnosis be cleared up, but also, if the case is one of meningitis, the nature of the invading organism will be determined. Lumbar puncture is the most useful therapeutic agent at our disposal in the treatment of meningitis. It relieves the intracerebral pressure and drains away toxins.

In cerebro-spinal fever (the meningococcus is the commonest pyogenic organism causing meningitis) anti-meningococcal serum given intrathecally has markedly lowered the mortality-rate. Even in the next common form of suppurative meningitis, namely, pneumococcal, a serum such as Lane's can be tried by the spinal route. This method will give better results than the unsatisfactory and retrograde procedure advised by Mrs. Fysh under the title "iodine treatment."

NOTE ON TREATMENT OF ACUTE GAS CASES.

DR. THOMAS D. LISTER (Consulting Physician for Lung Cases to the Prince of Wales's Hospital) writes: A method which I introduced at the Prince of Wales's Hospital for Officers (Great Central Hotel, Marylebone) last summer, of steam-spraying the air passages with Dobell's solution, I have now supplemented when necessary by using a fine oily nebula with cocaine 2 grains to the ounce, such as is given by the aeriser of Messrs. Oppenheimer with their No. 9 nebuline compound. This is used after the mucous membrane has been washed by the spray of Dobell's solution, or after coughing, and seems to afford relief. The addition of 1 per cent. cocaine and 1 in 10,000 adrenalin to a 2½ per cent. solution of boric acid also affords great relief to the eye conditions as a drop—a temporary measure which may be repeated.

THE FEAR OF SMALL-POX.

IN the *Revista de Medicina y Cirugia practica* of May 14th there is a story which illustrates the inhumanity which the fear of infectious diseases may produce among ignorant people. Stories of similar cowardice on a larger scale are told of Milan, Marseilles, London, and elsewhere in our own country during the great epidemics of plague which occurred in the middle ages, and down to the beginning of the eighteenth century. But that small-pox should still cause such terror, even in a backward country like Spain, must cause sad reflections to believers in human progress. In an outbreak of that disease which occurred in January last at Villavendimio (Zamora) the wife of the sacristan of the village was attacked. Her husband could find no one to help him in giving her the necessary attentions till the poor law medical officer, Dr. Fernando Perez Rodriguez and the parish priest, Don Felix Cabago, took it in turns to tend the patient. When she died the doctor, after giving directions for the disposal of the remains, returned to his other duties. Later on, meeting with the priest, he learnt that the body was still where they had left it, as the husband had failed either by entreaties or by liberal offers of money to find any one to help him in taking it to the cemetery. Thereupon they laid out the body, procured a coffin, and carried it to the cemetery, where they helped the gravedigger to bury the poor woman decently. The devotion of the doctor and the priest has aroused such admiration that a widely endorsed petition has been forwarded to the proper authority, asking that the Cross of Beneficence should be conferred on them.

PETROL FOR SCOTTISH PRACTITIONERS.

IT appears that some medical practitioners in Scotland do not order their allowance of petrol from local dealers until the close of the month, with the result that the necessary supplies may not reach the dealer's premises in time for them to issue the current month's quantity. In order to secure prompt delivery practitioners should send in their vouchers as early as possible in each month. Those who experience difficulty in this matter are invited to communicate with the Clerk of the Scottish Committee of the British Medical Association, 155, St. Vincent Street, Glasgow.

CERTIFICATES TO PROSTITUTES.

WE learn from a report in the *Folkestone Herald* of May 11th that during the hearing of a charge of soliciting against a prostitute the chief constable stated that the woman had in her possession "a certificate from a local doctor stating that he could find no trace of venereal disease on her. He presumed she kept that to show the men she accosted." This he thought was a new system. The chairman of the bench, in passing a sentence of fourteen days' imprisonment, accompanied by a recommendation for expulsion, said that it "seemed strange that a local doctor should give these certificates to prostitutes." In the next case, in which the charge was similar, the chief constable said that this woman also had a certificate from a local doctor, and the magistrate's clerk remarked that the certificate was given on the same day as the last case. From the facts as stated in the report before us we are inclined to agree with the chairman.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.

"VIS VERITAS" writes: Permit me to endorse all that "An Old Member" of the "Medical Sickness Society" writes concerning the injustice done to old members who rallied to its support in its early days. Formerly we used to get a small bonus every year, but this was stopped in order to give us a larger one on retiring from benefit. Now it appears we are to get nothing. I am inclined to think that the whole affair is *ultra vires* and might be contested.

THE HUMAN AND THE EQUINE FOOT.

MR. T. S. ELLIS (Gloucester) writes: In my narrative of the result of an accident to my own foot, given in the JOURNAL of May 25th, p. 608, there is an unfortunate slip. A sub-astragaloid dislocation involves a displacement of the bones in front of the astragalus and not of the astragalus itself.

THE appointments of certifying surgeons to the following places are vacant: Canterbury (co. Kent); Bishop's Waltham (co. Southampton); Gadgate (co. Lancaster).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE UTILIZATION OF THE MUSCLES OF A STUMP TO ACTUATE ARTIFICIAL LIMBS:

CINEMATIC AMPUTATIONS.*

BY

V. PUTTI, M.D.,

PROFESSOR OF ORTHOPAEDIC SURGERY IN THE UNIVERSITY OF BOLOGNA, AND DIRECTOR OF THE RIZZOLI (ORTHOPAEDIC) INSTITUTE OF THAT CITY.

It affords me the greatest pleasure to place before the British medical profession the facts as to what has been called cinematic amputation. I feel this all the more because I am thoroughly convinced of the enormous advance which the conception of cinematization will bring about in the treatment of disabled men, and believe that all that concerns this new current of ideas, as well as the store of facts related to them, ought to be placed at the disposal of the world at large.

In briefly reviewing the fundamental theories of plastic motors, and pointing out the vast field thus thrown open to the activity of orthopaedic surgeons and mechanical engineers through the practical application of these theories, I venture to express the hope that our efforts may prove welcome to all those who have hitherto had no opportunity of studying this important scientific innovation.

Whilst in Italy the tireless work of propaganda undertaken by Dr. Giuliano Vanghetti, the original exponent of these theories, has led to their full discussion and close study and to many experiments, and whilst both German and Austrian scientists have been actively working to obtain the most practical application of these same theories, the medical literature of France, England, and America contains very few, if any, allusions to the subject.

In the space at my disposal I must content myself with outlining the fundamental principles upon which the theory is based, pointing out, as briefly as possible, the various ways it can be put into actual practice, and making a short statement as to the method of operation and the results.

The possibility of utilizing the functional resources of the stump so as to convey movement to the artificial limb was an idea that came to Dr. Vanghetti first in 1896, at the time of Italy's second expedition into Abyssinia, when soldiers that had been taken prisoners by the native forces under the Negus were cruelly tortured and mutilated.

From that time onwards Dr. Vanghetti wrote and published innumerable articles, wherein he developed his theory on what he had now named "cinematic amputation." In them he described very fully the origin of his idea and the various methods by which it could be practically applied. Unfortunately for the speedy acceptance of this most novel and useful idea, Dr. Vanghetti, though his originality, cleverness, and ability are indisputable, is not a surgeon, but a physician, and for this reason was unable to put his theory into practice. He was therefore forced to resign himself to endless delays before he succeeded in convincing surgeons of the great value and practical possibilities of his theory and obtaining their co-operation, which was indispensable to any adequate test. This was the principal reason why, prior to the war, the cases of cinematic amputations did not number more than twenty.

THE PRINCIPLES OF CINEMATIZATION AND OF "PLASTIC MOTORS."

Dr. Vanghetti has given the name of "cinematic plastics" or "cineplastics" to any kind of bloodless or operative plastics that tends to economize, restore, or substitute those muscular masses that can be employed to impart direct and voluntary movement to an artificial limb.

The word "cinematization" was formerly used to indicate the cineplastic operation; it was subsequently applied to every kind of cinematic artificial limb, and finally to the active and early mobilization of such muscles as are involved in cineplastic operation.

Every moving entity obtained cineplastically, whether bloodlessly or operatively, is called a "plastic motor."

* Professor Putti, Professor Pellegrini, and Captain Pieri (Italian Royal Army Medical Corps), delegates to the Inter-allied Conference on the after-care of discharged sailors and soldiers, read papers and gave demonstrations on cinematic amputation and cineplastics in the section of the Conference on surgical treatment. Subsequently, Professor Putti summarized the present position of the subject in an address to the Royal Society of Medicine, the substance of which is here reproduced.

Plastic motors are based on the following general principle: In an amputation or disarticulation, actual or antecedent, the tendon and muscle, provided they have the necessary physiological protection—skin, vessels, nerves, etc.—can generally be used in cinematic prosthesis, on condition that the formation of an artificial point of attachment, to be protected in a similar manner, is available. Cinematization can be effected, or prepared, at the time that the primary amputation is made; it can also be done on stumps that have already healed.

Plastic motors may vary as to their number, position, shape, and function.

Without entering into too detailed a description of the numerous varieties of plastic motors, I will limit myself to stating that, at the present day the most elementary, and, up to now, the most commonly used are, as regards shape, the *clava* (*clavus*, a peg) and *ansa* (a loop) motors, and those obtained by means of the canalizing, or tunnelling, of the muscular masses.

As regards number, the motor may be single, double, or multiple; in function it can be either *unimotor* or *plurimotor*.

When the motor is made to execute two opposite movements in succession, it is called *alternative*.

According to the position they occupy, motors are either *terminal*, when placed at the extremity of the stump, or *extraterminal*, should they be placed in the continuity of the stump.

Down to the present time the upper limb has been more frequently cinematized than the lower, but the number of successful cases of cinematization of the lower limbs is daily increasing.

APPLICATION OF THE PRINCIPLES.

From what I have said, it will be evident that the application of cinematization entails essentially a radical upheaval of all preconceived notions as to the ordinary methods of amputation.

Principles observed in the performance of amputations according to prosthetic criteria have already caused a revolution in modern surgery, but they must again be subjected to modifications in order to ensure the preservation of the greatest possible amount of the original bone and of the residual motor masses and integuments, for these must be used for the preparation of the plastic motor.

In cases where it is practically impossible to perform primary cinematic plastic operations, as, for instance, at the first-aid dressing stations in the full stress of battle, the surgeon can, at any rate, always so operate as to prepare the ground for a future cinematization of the stump. Skin flaps, muscular insertions, various bone and tendinous fragments and segments of limb, which would seem utterly superfluous under ordinary circumstances for the preparation of ordinary stumps, must be recognized to be of the greatest value in view of the future cineplastics.

In order to prevent the possible loss of these elements and of these materials whilst the stump is undergoing the process of healing, it is advisable to take certain special technical precautions to avoid the retraction of the softer tissues; this ought to be done, however, in such a way as not to hinder the ordinary dressing of the wound.

When the inflammation has decreased, and further complications are no longer to be feared, the time has come for the actual cinematization, that is to say, for the preparation of the plastic motor or motors. A plastic motor, in order to fulfil the purpose with which it is made, must conform to the following requirements:

1. It must possess every requisite for withstanding a firm, resisting, and painless grip, and also a traction force that, in not a few instances, may be high.
2. It must be provided with a sufficient amount of muscle masses capable of functional movement to guarantee the accomplishment of the task that will be demanded of them.

The primary conditions for obtaining the first requisites are:

1. That the motors be covered with skin in perfect condition, well nourished, and possessing a normal degree of sensibility.
2. That, with regard to its shape and dimensions, the motor be of a size suitable for the fastening of the hooks, rings, and rods, that are destined to transmit the functional movement to the artificial limb.

The "Clava" Motor.

The movement masses must be sought for, and obtained from amongst those which the stump still possesses. Such masses as from their anatomical structure and physiological disposition produce broad, strong, and dissociated contractions, are the best adapted to the task. In the choice and distribution of these masses the fundamental principles of the physiology of movement must be thoroughly observed and respected.

As the tendon is the element best adapted for the transmission of muscular contractions, it should be largely employed for the formation of plastic motors. Should the tendon be missing, the muscles must be utilized either by including muscular bundles within the terminal motors, or by tunnelling the muscular masses in order to obtain the extraterminal motors.

The antagonistic force, indispensable to all active movement, must be provided either by the stump itself through the formation of two motors with elements belonging to muscular groups of opposite action, or by the artificial limb by means of elastic resistance in the opposite sense to that given by the plastic motor.

With a view to gaining both space and integument it may be advantageous at times to shorten slightly the bone or bones of the stump, and to excise superfluous muscular masses. This, however, can only be done when the bone is sufficiently long to allow it.

In order to provide such materials as may be missing *in loco*, recourse may be had to the numerous methods that modern plastic surgery places at our disposal, as, for instance, skin, muscular, aponeurotic, or osseous transplantations. Arthroplasties, with the interposition of an aponeurotic flap, may be utilized so as to render mobile those stump segments which, through stiffness and ankylosis, have become unusable. By these same means a new joint can be created in the continuity of the stump, thus giving the plastic motor the power to develop a leverage action.

The cinematization of the thigh stump enables us to solve one of the most difficult prosthetic problems—that of gaining active power over the knee-joint. With the ordinary artificial limbs the knee extension is obtained either by means of springs or of elastics, quite independently of the will of the patient, or else through straps put on the stretch by auxiliary movements of the trunk and shoulder. In some cases we have carried out successful experiments by cinematization of the quadriceps femoris; then the stump itself can control the voluntary extensor movement of the knee, and restrain the flexor movement.

As a result of cinematic plastics we are now able to utilize certain stumps which hitherto have always been held as incapable of functional movement, such as, for instance, carpal stumps, very short stumps, and disarticulation stumps.

The surgeon who, in the case of shoulder disarticulation, succeeds in sparing the deltoid and pectoralis major, in covering these muscles with skin, and in finding means of creating a point of attachment, may be congratulated on having preserved for the benefit of the mutilated man a precious functional capital.

With regard to the difficult problem of utilizing short forearm or short leg stumps, the solution will be enormously facilitated through the preparation of points of attachment that correspond to the insertion of the biceps and patella tendons.

[In order to illustrate the fundamental principles of cineplasties, Professor Putti demonstrated a number of plaster casts of amputated stumps, in which he had prepared different kinds of plastic motors. The first cast was of the stump of a forearm with two terminal motors; one of these had been formed with the tendons of the flexor muscles, the other with the tendons of the extensor muscles. It was a case of disarticulated wrist, and the stump was already completely healed. After excising about an inch and a half of the radius and of the ulna, two cutaneous flaps were prepared, each of which served to cover the two principal groups of tendons in the forearm, that is to say, the flexor and extensor tendons. Professor Putti thus obtained two plastic motors like clumsy fingers, of which one was controlled by the flexor, the other by the extensor muscles.]

Two points of attachment must be provided in these two "fingers," in such a way as to ensure the transmission of

their contractions to the artificial limb, with a view to giving movement to the hand. This I obtained by means of metal rings covered with vulcanized rubber placed at the base of the fingers, and gradually tightened; to them the artificial motors of the hand were attached. The stump thus became capable of giving flexor or extensor movements to the artificial hand.

In cases in which it is not possible to obtain sufficient material for the construction of two motors, we must limit ourselves to the preparation of a single motor, the antagonistic movement being provided in the artificial limb by a spring or an elastic.

The "Ansa" Motor.

Another type of plastic motor is that known as the *ansa* motor. In the case from which the cast exhibited was taken, after shortening sufficiently the radius and the ulna, I prepared the tendons of the flexor and extensor muscles, and gathered them together in such a way as to form a ring or loop, which I afterwards covered with skin. Whenever the disabled man contracts either of the two muscular groups, this ring, or loop, displaces itself alternately either in a flexor or in an extensor sense, and the contractions are transmitted to the artificial limb.

The plastic motors so far described are formed of the soft parts of the stump. In order to give greater consistency to the motors they can be provided with a bony support.

ILLUSTRATIVE CASES.

The stump in the first case demonstrated is from a case of disarticulation at the wrist. I formed a para-epiphyseal pseudarthrosis, excising from a third to a fourth of an inch of bone from the shafts of the radius and of the ulna and then interposing a double flap of fascia and of muscle. I was thus able to obtain an artificial wrist having all the movements with which, normally, the wrist is provided, for the muscles and tendons that cause these movements had been, for the greater part, preserved.

I performed a similar operation on the stump of an arm. Having detached a fragment of bone from the extremity of the humerus at the height of about one inch, I interposed a muscular flap between the severed section of the bone. Thanks to the neo-arthritis, the stump is capable of flexor and extensor movements, for into the piece of severed bone the muscular bodies of the biceps and of the triceps are still inserted.

I believe that these cases sufficiently show the principal types of terminal motors. As regards their preparation, it is nearly always necessary, as I have said, to sacrifice a certain quantity of the stump's original bone. But plastic motors can be obtained without compromising the length of the bone. This is achieved by directly tunnelling the muscular bodies.

In the forearm stump I prepared the group of the flexor superficialis, preserving its normal cutaneous envelope. By a plastic operation I next covered with skin the space comprised between the superficial flexor and the deep flexor, thus creating a canal completely lined with skin. During the period that the wound was healing I maintained this canal open constantly by means of a rubber tube. Once the cutaneous wounds had healed, I inserted a metal rod covered with vulcanized rubber in place of the rubber tube. This little rod serves as point of attachment for the cords used to convey movement to the artificial hand. Following each contraction of the flexor muscles, this small rod displaces itself in a proximal sense, and thus actuates the fingers of the hand.

Arm and thigh stumps are better adapted to this style of cinematization than are those of the forearm. I show casts of two stumps of the lower third of the thigh in which I prepared a canal running horizontally and to the full depth of the quadriceps a little above its insertion into the patella. Into the canal I introduced a skin flap folded back over itself in such a way that the cutaneous surface was turned towards the lumen of the canal. The tunnel thus formed is entirely lined with skin, and can withstand, without risk of damage or pain, the presence of the metal rod that serves for the transmission of the extensor movement to the artificial leg.

At the first glance it may appear strange that these mechanical attachments can be so easily tolerated. Experience has proved, however, that if the plastic motor is well placed, if the skin that covers it is healthy, if the

wounds are absolutely healed, neither the rings nor the rods cause the slightest harm. When the *clava* motor is sufficiently long, and its head is large enough, the ring surrounding the neck of the *clava* need not be tightened to such an extent as to interfere with the blood supply of the motor. Moreover, each ring is provided with a screw by means of which the disabled man can himself regulate the pressure.

The disabled men get so accustomed to the metal rod that they leave it in place even at night. The rod must, however, be removed once every twenty-four hours, in order to clean it with alcohol and oil it with vaseline. I have observed that the skin within the canals gradually acquires the property of throwing off sebaceous substances in greater quantities than normal, thus providing for the oiling of the canal.

FUNCTIONAL RESULTS.

Another point deserving consideration is the sensibility of the plastic motors. Professor Amar has made some most interesting physiological researches, showing that the superficial and deep sensibility, and the muscular sense of the stumps, which at first—that is, shortly after the amputation—are greatly altered, not only recover in time, but eventually attain a degree of sensibility superior to the normal, provided the stump is put through the proper functional training. I have observed that the same thing happens with cinematized stumps. One of my patients, on whom I operated over a year ago, is now able to note with considerable exactitude the difference in the size and weight of the articles which he seizes with his artificial hand.

The functional results that can be obtained from a plastic motor depend upon numerous factors, but especially on the cinematic powers of the muscular masses of the stump, on the manner in which the surgeon has found it possible to utilize them, and upon the functional use the motor undergoes. To give a clear conception of the amount of work that a plastic motor can do I may state that amongst the cases operated upon by me the power of the motors ranges from 10 kilogram-centimetres at the lowest to 100 kilogram-centimetres at the highest. For a motor to be of practical use it must be contracted not less than one inch. In the case of a hip stump, I have obtained one motor that contracted to the extent of two and one-fifth inches, lifting a weight of forty-four pounds.

I have only described the principal types of plastic motors. The genius and the ability of the surgeons will find here a vast field of action. Naturally, it is not possible to treat all amputated stumps in this manner. Those that best lend themselves to it are those that include healthy muscular masses, that retain normal innervation, and that possess an ample contractility. Stumps with rigid or ankylosed joints, covered over by skin that does not glide easily, being adherent or creased by a scar, do not supply satisfactory plastic motors. The age, and moral and intellectual condition of the patient are also important. The best age is from twenty to thirty years. Disabled men of insufficient mental development, or those who are not likely to be willing to follow with patience and assiduity the necessary functional training of the stump muscles, ought not to be operated upon.

It is to be understood that cinematization does not invariably require operations with the knife. There are stumps already formed which are endowed spontaneously with cinematic resources that, wisely employed, can be utilized for transmitting movement to the artificial limb. I will content myself with mentioning the wrist and forearm stumps, in which rotary movements are preserved, and the arm and forearm stumps, that possess a terminal hood having a development and contractility sufficient to ensure a good grip.

CONSTRUCTION OF SUITABLE ARTIFICIAL LIMBS.

Whatever type of plastic motors may be chosen, it is an essential condition for their efficient utilization to their full value that the artificial limb be adapted in a manner suitable to their power, their number, and their shape. This question of cinematic prosthesis is so vast and still so new that it deserves a special study to itself. It is now undergoing gradual development and will bring about a substantial reform in ordinary constructive methods. The surgeon, the physiologist, and the mechanic must all

collaborate intimately in this work, as only by means of the perfect fusion of these three can we obtain new methods of a really scientific character that will answer modern requirements and replace the empirical systems that have been followed up to now in the manufacture of artificial limbs.

[Professor Putti demonstrated specimens of artificial limbs especially constructed for cinematized stumps. Among others three hands, of which two were made for stumps with a single plastic motor; in one the contraction of the motor is used for opening the hand, which was kept closed by means of a spring; in the other the motor closed the hand. The third hand was made for a stump with a double motor; the movement of closing and opening the fingers was wholly controlled by the two motors. He showed also appliances representing various types of artificial limbs for forearm stumps, and continued as follows:]

The construction of the artificial limb is greatly simplified by the possibility of utilizing the intrinsic powers of the stump. The mechanical contrivances hitherto used for moving the fingers are most elementary; the cords, the levers, and the springs used for conveying movement to the hand by utilizing the movements of the elbow and of the shoulder can now be completely done away with, and the disabled man rendered able to open or close the fingers in any position of the limb. Even workmen's tools can be used in a practical way by the cinematized stump, and a special pincer shaped like a parrot's beak has been devised for the use of workers in metal.

RESULTS.

As to the ultimate results of the cineplastic method, no final judgement is as yet possible for though the idea was conceived over twenty years ago, cinematization has been applied on a larger scale only since the beginning of this war.

The very few cases of operations of this type performed prior to the war—almost exclusively by Italian surgeons—had afforded sufficient proof of the soundness of methods, but they had not provided enough material to enable us to judge with regard to their practical usefulness. Only since the beginning of the war, when the necessity of giving practical aid to the vast and tragic army of disabled men came to the fore, were our surgeons convinced of the expediency of testing the principles and methods of cinematic surgery. We are yet at the very beginning of this new scientific movement, and the surgeons of all allied nations have not as yet contributed to it.

The German surgeons have followed Sauerbruch's example, and, although they have created an admirable scientific organization, they have limited themselves to the repetition of a single type of plastic motor. Consequently, in analysing the results obtained by them, we can form but a partial judgement of the practical value of cinematization. The number of operations performed by Italian surgeons is probably inferior to those done in Germany, but the variety of the motors experimented upon by us is certainly greater.

It is easily understood that, for the moment, it would be impossible to make a synthesis of such a variety of facts. I therefore believe that it will prove of greater benefit, in discussing the results that have been obtained through cinematization, to consider the question solely and exclusively from the point of view of my own cases.

These number about fifty examples of cinematization of the upper and lower limbs, either primary or secondary; plastic motors of various types were formed, and in each case an artificial limb was applied. The functional value of the motors was studied by dynamographic and dynamometric methods, whilst their practical capacity was tested in the actual use of the artificial limb.

At the Instituto Rizzoli I have at my disposal a large workshop for the construction of artificial limbs, so that I have been enabled to study cinematic prosthesis as well; this, as I have already said, constitutes one of the most important sides of this complex question.

CONCLUSIONS.

The researches that have been made in the Institute have brought me to the following conclusions:

1. The practical results that have been obtained through cinematization have convinced me that the hopes aroused by the principles and methods of the modern theory of

plastic motors are thoroughly well grounded. Cinematic plastics are entitled to be placed amongst the most brilliant of the discoveries of orthopaedic surgery, deserve to be accepted with perfect confidence, and to be tested on a large scale by all those whose aim it is to restore to the disabled man his functional activity.

II. The preparation of plastic motors is a well-defined surgical act that must be performed in accordance with its own special methods, which have already stood the test of experience.

III. From a physiological point of view plastic motors have been proved capable of giving both the quality and quantity of action of which the muscular masses that stimulate the said motors are capable. Yet, practically considered, plastic motors will yield the full measure of their value only if the artificial limb is perfectly adapted to their shape and their strength.

IV. As the principal aim of cinematization is to attain the vitalization of the artificial limb, it is essential that the surgeon and the artificial limb maker should work in harmony, in order to solve satisfactorily this most interesting but difficult problem.

Demonstration of Moving Pictures.

Professor Putti exhibited a number of moving pictures to illustrate the results of cinematic amputations. They included arm and forearm stumps with plastic motors, and demonstrated very well the power the man had over single or double (flexor and extensor) plastic motors. In other cases terminal "ansa" motors of the forearm were shown, and the power of the patient to lift a weight demonstrated. The films showed both the bare stumps and the same men fitted with artificial arms and hands. Two other films showed cases of cinematization of thigh stumps, plastic motors being obtained by tunnelling the quadriceps femoris. The patients were also shown wearing artificial legs. The ease with which they could raise the limb with the knee in extension, and the advantage the plastic motor gave in walking were clearly shown.

THE RELATION BETWEEN HEAT-STROKE AND MALIGNANT MALARIA.

(Preliminary Note.)

BY

CAPTAIN C. E. H. MILNER, R.A.M.C.(T.F.),
REGISTRAR, — B. G. HOSPITAL, MESOPOTAMIA.

HAVING been intimately connected with the study of heat-stroke and malaria throughout the record heat in Mesopotamia during the summer of 1917, I feel bound to record certain conclusions to which I have been forced as a result of observation.

That there is a close relation between the two conditions is beyond question; and this paper is written (in full consciousness of its heterodoxy, and in confident anticipation of much adverse criticism) in order tentatively, and with all humility, to suggest that heat-stroke as a

clinical entity is non-existent, and is nothing more than a symptom, on a hot day, of malignant tertian malaria.

One of the clinical pictures with which one soon became familiar was that of a thick-necked, middle-aged man, who would be admitted to hospital, in the cool of the evening, still unconscious, and with a temperature of about 108° F. In his own camp, about middle day, this man would have been seized with sudden headache, vertigo, and unconsciousness—sometimes with violent maniacal delirium. He would have been treated locally by means of cold sponging, and perhaps an ice-pack—for this year (1917) there has been no shortage

CHART 1.—A, On admission.

of ice—and he would have been transferred to hospital as soon as ever the heat of the day were over. (It were certain death to attempt to transfer such a case before 4 in the afternoon at the earliest, with a maximum shade temperature of 125° F., such as we had

in July of this year.) Such a case would, on admission, be taken direct to the heat-stroke station and treated symptomatically in the usual routine manner—by means of venesection, infusion, rubbing with ice, and copious ice enemata.

Another common picture was that in which the heat-stroke "super-vened" upon another disease. And in this the characteristic thick-necked, middle-aged, rather alcoholic type was conspicuous by its absence. This time the patient would be already in hospital suffering from some quite other complaint—sandy fever, dysentery,

even malaria itself. And there was no type that one came to recognize as being especially associated with this form of heat-stroke. The patient would feel the heat a great deal in the early afternoon—might even beg one to give him "something to make me sweat, sir," and was almost

CHART 2.—A, On admission, 6 p.m., the temperature was 103.2°; it did not rise above normal after September 5th.

CHART 3.—Q, Quinine gr. x, thrice daily.

CHART 4.—Q, Quinine gr. xv, thrice daily.

invariably constipated. One afternoon he would become very restless in bed, and in a very short time unconscious, with a rectal temperature of 108° or 109° F.

This year there were two formidable heat waves—the one in July and the other in August (1917). It was not

CHART 5.—July, 1917.

CHART 6.—August, 1917.

until the second of these that it became the custom in this hospital to make an immediate routine examination of a blood film for the presence of malaria parasites. In view of the very high percentage of heat-stroke cases whose blood was found to contain the parasite of malignant

tertian, it became the practice during the second heat wave (even before receiving the laboratory report) to administer an intramuscular injection of 8 or 9 grains of bihydrochloride of quinine.

The mortality during July was as high as 25.65 per cent.; that during August, when quinine was always administered immediately, was only 11.76 per cent. This, to my mind, is the most striking factor pointing to malignant malaria as being the primary cause of hyperpyrexial heat-stroke. For it was not until the second heat wave that quinine was given as a routine, and during this period the death-rate fell by well over 50 per cent.

Starting with the physiological assumption that there is a heat-regulating centre, it is reasonable to suppose that one of the symptoms of an infection with the parasite of malignant tertian malaria is the intoxication of this area. It readily follows that, when once the heat-regulating apparatus is upset, the body must naturally assume, as nearly as possible, the temperature of the atmosphere. Thus it is a fallacy to suppose that heat-stroke supervenes if one stops sweating. The truth is, on the contrary, that a patient ceases to perspire because he has got heat-stroke, because he is suffering from paralysis of the heat-regulating centre, due to intoxication by the parasite of malignant tertian malaria.

The clinical charts 1 to 4 will serve to illustrate the marked hyperpyrexia which has been observed even in cases which have recovered, and which have appeared mentally to be none the worse for their illness. All the charts are of cases which were regarded as "heat-stroke," in which were observed the classical symptoms described as being those of heat-stroke, and yet in the blood of each and every case were found the characteristic ring forms of the *Laverania malariae*, the parasite of malignant tertian malaria.

Charts 5 and 6 show the maximum dry and wet bulb thermometer readings for July and August, 1917.

BASAL LEPTO-MENINGITIS RESEMBLING BOTULISM.

By SYDNEY T. STEWARD, M.B., CH.B.,
ASSISTANT MEDICAL OFFICER, INFIRMARY, NEW CROSS,
WOLVERHAMPTON.

WHILE so much interest is being aroused by cases which resemble botulism, it may be well to record the particulars of the following case, which for a few days was thought to be that disease:

F. P., a girl aged 5 years, was admitted under my care on May 14th, 1918. There was a history of ten days' previous illness; she had seemed drowsy, and had vomited repeatedly for the first two days. For a month previously she had been feeding on "porridge, bread, sausages, chitterlings, and ham."

On admission, the temperature was 99° F., the pulse 100, and respirations 20. She was drowsy, but by no means comatose, and realized her surroundings sufficiently to "want to go home." She was very irritable, and complained of pain in the head and back. There was no paralysis; the eyes were kept closed, though she could open them; the pupils were dilated. There was very slight head retraction, but Kernig's sign was absent. The tongue was very foul, and the breath fetid. The bowels had not been open for at least four days previous to admission. She was incontinent of urine. Castor oil was administered without effect.

On May 15th calomel gr. $\frac{1}{2}$ was given hourly for twelve hours, with the result that the bowels were open three times the next day, when she seemed more wideawake and sat up in bed, but was still very refractory and resistive so that the reflexes could not satisfactorily be determined.

On May 17th the respirations assumed a Cheyne-Stokes character, combined with marked slowing—at midday they were only 7. This continued for three days, the respirations never rising above 16 till the evening of May 19th, when they were 20. I performed lumbar puncture in the afternoon; the cerebro-spinal fluid came away under greatly increased pressure; it literally shot out; about 28 c.cm. were removed. Immediate microscopic examination showed it to contain fresh red blood corpuscles, presumably the result of the puncture. The fluid was sent to a pathologist, who discovered no other abnormality in it.

On May 18th there was low delirium; respiration continued slow, the tongue still furred, the head still a little retracted, the pupils still somewhat dilated, and Kernig's sign still absent. There was left-sided facial palsy with inability completely to raise the left upper eyelid. The knee-jerks were absent. At times the child cried out, but not with

a typical meningeal cry; at others she lay "as if dead," as the sister put it. From this day onward hexamine in 5-grain doses was given three times a day.

On May 19th she seemed a little improved. Both eyes were well opened, and the facial palsy was much less marked. The mouth was still dry, but she took milk much better. She lay quieter, and her forehead, which hitherto had been constantly wrinkled into a fixed frown, was placid. During the night of May 19th-20th some blood-stained mucus came from the nose and mouth. The stench was horrible.

On May 20th she was incontinent of urine and faeces; her brow again assumed the frowning expression, and she cried out continually. The pulse was running and somewhere about 200.

On May 21st the discharge from the nose and mouth continued. The heart was failing, the pulse was still running, about 200, the respirations were 62, and she was deeply cyanosed. Kernig's sign was still absent. At 10 p.m. the chest was full of coarse râles, and there were generalized convulsions. She died a few minutes later, with a temperature of 104.8° F. A morning and evening temperature chart is attached. The four-hourly chart was no further help.

Post-mortem Examination.

The pia mater showed general hyperaemia, whilst over the base of the brain, especially over the optic chiasma, pons, and front part of the medulla, the meninges were swollen, oedematous, and jelly-like. There was no definite pus, though between some of the convolutions there seemed to be a little turbid fluid. On section the brain showed no gross naked-eye changes. The other organs were healthy.

The signs and symptoms which were thought to point to botulism were vomiting, transient facial palsy, transient ptosis, absence of spinal paralyses, drowsiness, absence of temperature, and constipation with dryness of the mouth and nose.

THE EARLY AND EFFECTIVE REDUCTION AND FIXATION OF GUNSHOT FRACTURES OF THE FEMUR.

By O. HERBERT WILLIAMS,
CAPTAIN (TEMPORARY MAJOR) R.A.M.C.(T.F.).

THE adoption of the Thomas splint in the treatment of compound fractures of the femur caused by gunshot wounds has done much to alleviate the suffering resulting from the injury, has saved many lives and limbs, and has led to much improved functional results.

From the casualty clearing station at the front to the general hospitals at the base there is every facility for the application of the splint and the carrying out of the principles which its use entails. In front of the casualty clearing station, however, these facilities are not forthcoming, and the full value of the splint has not been obtained owing to the difficulty of applying simple and efficient first-aid extension.

At the regimental aid post the use of extension by adhesive strapping or glue and calico bandage, applied to the skin, is out of the question; nor is it advisable, having in view the fact that an anaesthetic will have to be administered and an operation performed at the casualty clearing station, to adopt these measures at a field ambulance.

The ideal method of procedure, then, would be to employ so simple a method of extension that it can be applied at, or as near as possible to, the spot where the casualty occurs; and which is at the same time easy and rapid of application, efficient, and need not be changed till the patient is on the operating table at the casualty clearing station.

Before describing any method in detail, it may be well to devote a little time to the following considerations.

(a) *Evacuation and the Time Required to Carry a Casualty along a Trench System.*

Usually the first point at which effective measures can be taken in the treatment of these cases is at the regimental aid post, which is generally situated at the rear portion of a system of trenches. Most of the casualties, however, occur some distance from this point, and the route to be followed to reach it may be over shell-pitted ground and through narrow, tortuous, angular, and congested trenches. To carry a casualty over a few hundred yards of such difficult route may take as much or even more time, and involve much more jolting and jarring of the limb, than would his conveyance in a motor ambulance over, say, five miles of moderate road. Evacuation along a trench system, then, is a matter of great importance and merits serious consideration.

(b) *Difficulties Peculiar to the Injury Itself.*

A fractured femur, of all injuries, is the one that presents most difficulty in transport, unless some effective measures are taken with this object in view. The lower limb, forming as it does a large proportion of the body weight, becomes a large, heavy, and particularly unwieldy mass, which rolls about helplessly, causing most agonizing pain and damage to tissues in the region of the fracture. The upper limb is less bulky and unwieldy, and if injured and helpless the other limb can come to the rescue. This not being the case with the lower limb, early and effective splintage becomes all the more imperative.

(c) *The Seriousness of the Injury.*

From the point of view of mortality, it should be placed in the same category of urgency as a brain injury or perforating abdominal wound. It requires very little consideration to convince oneself of this. The largest bone in the body is shattered; the missile and the fragments of bone, with their imparted momentum, tear up powerful and massive muscles; even if the main vessels escape injury, there must inevitably be a considerable amount of haemorrhage which escapes out of the wound or infiltrates the tissues, causing the limb to become tense.

(d) *The Importance of Applying Extension at the Earliest Possible Moment.*

The early complications responsible for the high mortality in these cases are shock and gas gangrene, and they occur in about equal proportions. At no section of the line of evacuation do the causes of these complications act with greater intensity than they do during the regimental

stretcher-bearer's "carry" to the regimental aid post. There is gross shortening, with lateral and rotary deformity; the spasm of powerful muscles and the rolling of the limb cause the fragments to grate one upon the other, and vessels and nerves may be wounded. Muscles are prodded and lacerated by sharp fragments; and infective material that has been introduced becomes much more

intimately incorporated with the injured tissues. A process of mechanical devitalization takes place during this period that no subsequent measures that may be taken can retrieve.

First-aid Considerations.

From the foregoing considerations it is obvious that more

effective first-aid measures must be taken in front of the regimental aid post, and should, whenever possible, be carried into effect at the place where the casualty occurs. Such measures as tying the injured limb to the sound one, or making extension and counter-extension to the poles of the stretcher are certainly serviceable, but they are far from being effective in the sense of complete extension and immobilization. The measures taken, then, will have to be carried out by the regimental stretcher-bearer, and under difficult conditions. They must therefore be simple, effective, and rapid of application.

As has already been indicated, the main difficulty lies in the application of extension, and to overcome this difficulty the brace described below is suggested.

THE EXTENSION BRACE.

The brace, which is intended for application over the boot, is made of strong webbing in the form of two Y's, one of which lies on each side of the boot (Figs. 1 and 2). The diverging limbs of the Y's merge into each other so as to form an anterior or dorsal strap in front of the ankle, and a posterior or heel strap behind the ankle. On one side they are fastened together by means of a stud. The stem of each Y forms a loop to which strong cloth strapping is stitched.

Details of Construction.

Strong webbing, similar to the webbing of a small box respirator, 2 in. wide, is used. It is cut into four pieces, two of which are 10 in. long to form the anterior and posterior straps, and two of which are 12 in. long to form the loops (Fig. 3).

The ends A of the anterior and posterior straps are sewn together at an angle of 90 degrees, and the loop is sewn to this junction in such a way as to bisect the angle, and form with strap an angle of 135 degrees (Fig. 4).

Of the ends B, that of the anterior strap is sewn to one end of the loop strap at an angle of 135 degrees, and that of the posterior strap to the other end of the loop strap at a similar angle. A metal stud is placed at the anterior strap-loop junction, and a corresponding stud slit is made at the posterior strap-loop junction. The stud slit must be in line with the loop strap. It is important that the anterior and posterior straps be not longer than 10 in., otherwise the brace does not maintain so effective a grip on the boot.

Three feet of strong cloth strapping, 1½ in. wide, is stitched to each loop to form extension straps.

The advantages of the brace are that:

1. It allows of strong and efficient extension being made with a minimum of discomfort.
2. There is no possibility of it coming off, as the

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

greater the extending force the tighter and more secure the grip.

3. There is no constriction of the ankle or pressure on the malleoli.

4. The foot is maintained at right angles to the leg, and the limb cannot roll.

5. It can be put in position in two seconds.

6. When not in use, it can be compactly and securely fixed to the splint and so be always available.

I have submitted this brace to Colonel Sir Robert Jones, O.B., and he has expressed his approval of it.

The Slings.

The slings are made of strong calico bandage and five are required for each splint.

To make a sling, take a piece of strong calico bandage 4 in. wide and about 40 in. long. Each piece is doubled on itself and the loop so formed fixed to the inner bar by safety pins or stitching (Fig. 5). The free ends are split into tails of equal width for a distance of about 10 in. and serve for tying to the outer bar. When in use the tail A is tied to A' and B to B'. Three of the slings are supporting, and are placed under the ankle, knee, and thigh respectively; two are fixing, and are placed one above and one below the knee. The latter prevent flexion of the knee and rolling of the limb.

All Thomas splints in advanced medical units should be prepared for immediate use by having the brace compactly fixed to the junction of the ring and inner bar, and the slings fixed, rolled round, and tied to the inner bar, as depicted in Fig. 6.

Application of the Splint.

When the splint is about to be applied the brace is taken off, the slings unrolled and left to hang by the inner bar. One stretcher-bearer applies the brace over the boot and with it extends and rotates the limb into its correct position; this having been done extension is maintained by steady traction on the brace (Fig. 7).

No. 2 stretcher-bearer then passes the splint over the brace and boot, No. 1 still maintaining extension, first with one hand then the other, so as to allow of this being done (Fig. 8).

Being satisfied that the ring of the splint is well

up into the groin and pressing against the tuber ischii, No. 1 ties the extension straps of the brace to the foot of the splint as described below, and depicted in Fig. 9, A, B.

Pass both extension straps over the bars, cross underneath and then round the bars again to the U loop at the

foot of the splint. The straps must pass round the U loop in opposite directions, and be secured by a single knot. One strap is then passed under the crossing (Fig. 9, A), up between it and the sole of the boot, and tightened till the necessary extension is made. The free ends of the straps are now tied off at the U loop. The applied strap then assumes the appearance represented in Fig. 9, B.

The supporting slings are now tied, commencing with the one remote from the wound. This means that the ankle support is tied first and then the knee or thigh support according to the site of the injury. Lastly, the fixing slings are tied above and below the knee (Fig. 10).

The application of the splint only has been described above, and the question of dressings has been left out, in order to simplify the description and because at this stage, unless bleeding is considerable, dressing is of secondary importance to reduction and fixation.

Whether or not the wound should be dressed before the patient is conveyed to the regimental aid post will depend on

many factors, such as the number of casualties to be collected, the amount of shelling that is going on at the time, the superficial extent of the injury, and lastly, the amount of haemorrhage.

Except in the last contingency, the dressing should be done last, as it can be done more effectively and with less pain and detriment to the patient after extension and fixation have been secured. Access for dressing is obtained by cutting open the trousers over the site of the wound; the dressing having been applied, it is secured by a bandage passing over the bars of the splint. In this way, should a second dressing be necessary, it can be done without disturbing the extension and fixation.

The patient can now with relative ease be lifted on to the stretcher. The projecting end of the splint is supported on a block of wood, brick, or article of equipment to keep the heel off the canvas.

On arrival at the regimental aid post a suspension bar is fitted on to the stretcher to replace the improvised support, the extension brace is further tightened if necessary, and, should it be deemed advisable, a Jones's gutter-splint or a piece of Gooch splinting is inserted under the ham by loosening the supporting slings, one at a time, and retying them.

The various measures for the prevention of secondary

FIG. 7.—Traction applied to brace.

FIG. 8.—Introduction of splint.

FIG. 9.

FIG. 10.

shock are not within the scope of this paper, and mention only will be made of the importance of conserving the body heat by properly adjusted blankets; the application of warmth by hot-water bottles, hot bricks wrapped in sacking, or petrol cans and rum jars filled with hot water; the provision of hot drinks, the administration of a

hypodermic injection of morphine, and, lastly, speed in evacuation.

In order that a prepared splint may be within easy reach of any part of a trench system in which it may be required, it is suggested that they be taken to the front line; and that one at least should be kept in each stretcher-bearer's dug-out. As each case with a splint is brought to the regimental aid post, a prepared splint is given to the bearers to replace it.

CONCLUSIONS.

In conclusion, the following points may be emphasized:

1. The extension brace provides a standardized, simple, and effective means of extension, which is more rapid of application than any improvised method.

2. The Thomas splint, prepared as described, forms a complete armamentarium for "putting up" a fractured femur and does away with the necessity of carrying accessories. It is therefore well adapted for taking to the front line trench.

3. By having the fracture reduced and the limb extended and immobilized before the casualty is carried to the regimental aid post, the process of mechanical devitalization that takes place during this period more than any other in the line of evacuation is reduced to a minimum, and will lead to much improved functional results and reduce the mortality.

I have to thank Captain Edmund Price, R.A.M.C., for the figures illustrating this paper.

AGGLUTINATION IN THE DIAGNOSIS OF DYSENTERY.

BY

LIEUT.-COLONEL C. J. MARTIN, F.R.S., A.A.M.C.,

CAPTAIN P. HARTLEY, R.A.M.C.,

AND

SISTER F. E. WILLIAMS, A.A.N.S.

THE VALUE OF AGGLUTINATION IN THE DIAGNOSIS OF DYSENTERY CAUSED BY *B. DYSENTERIAE* SHIGA AND THE MANNITE-FERMENTING GROUP OF DYSENTERY BACILLI RESPECTIVELY.

DURING the later months of 1917 we tested the agglutination titre of all patients who were suffering or had suffered from dysentery. The examinations were made between the tenth and thirtieth day from the onset of the illness. We also tested the serums of 214 control persons who had not had dysentery, and who had no recollection of having suffered from diarrhoea during the past two years.

Our observations are divided into three groups, as shown in Tables I, II, and III.

Method.

The method employed was that recommended by Major Dreyer, namely, keeping equal volumes of the emulsions and progressive dilutions of the serums in a bath at 55° C. for four and a half hours and reading after fifteen to thirty minutes. The emulsions employed in the first series of our observations were supplied from Professor Dreyer's laboratory at Oxford. A degree of agglutination which could be comfortably seen with the naked eye against a black background corresponding to Dreyer's "standard agglutination" was taken as the end point. The results are expressed in terms of Dreyer's standard agglutinin units¹ by taking into account the factor on the bottle representing the relative agglutinability of the particular sample according to its behaviour with some arbitrarily selected serum.

The results obtained are set out in the following tables:

TABLE I.—Observations on the Serum of Patients from whose Stools Dysentery Bacilli were isolated.

Total number of positive Flexner cases, 151.

Number yielding 5 units	...	79 = 52 per cent.
" " 7 "	...	76 = 50 "
" " 10 or more units	...	58 = 38 "

Total number of positive Shiga cases, 13.

Number yielding 5 units	...	13 = 100 per cent.
" " 7 "	...	13 = 100 "
" " 10 or more units	...	13 = 100 "

TABLE II.—Observations on the Serum of Patients who had Suffered from Dysentery but from whose Stools Dysentery Bacilli were not recovered, nor *E. histolytica* found.

Total number of cases of clinical dysentery, 342.

Flexner:

Number yielding 5 units	...	76 = 23.4 per cent.*
" " 7 "	...	70 = 21.5 "
" " 10 or more units	...	40 = 12.3 "

Shiga:

Number yielding 5 units	...	17 = 5.0 per cent.
" " 7 "	...	17 = 5.0 "
" " 10 or more units	...	11 = 3.0 "

* The 17 Shiga cases have been deducted from the total of 342 in calculating the percentages.

TABLE III.—Normal Persons.

Total number of normal serums examined, 214.

Flexner:

Number yielding 5 units	...	23 = 10.0 per cent.
" " 7 "	...	17 = 8.0 "
" " 10 or more units	...	5 = 2.5 "

Shiga:

Number yielding 5 units	...	7 = 3.3 per cent.
" " 7 "	...	6 = 2.8 "
" " 10 or more units	...	4 = 2.0 "

The "Y" emulsion issued by the Standards Laboratory at Oxford was not agglutinated by the serum from patients of this epidemic except in a few cases (see Table IV below).

TABLE IV.

Group of Cases Examined.	No. of Cases Examined.	Agglutination with "Y" Emulsion.	Per Cent.
Positive Flexner cases ..	102	2	2.0
Clinical dysentery cases ...	172	6	3.5
Normal persons	52	—	—

The serum of normal persons may contain agglutinins to *B. dysenteriae* Shiga and to dysentery organisms of the Flexner-Y group in amount sufficient to cause confusion in diagnosis.² Ledingham and Penfold³ (1915) concluded from their observations that agglutination by dilutions of 1 in 50 in the case of *B. dysenteriae* Shiga and 1 in 200 in that of the Flexner-Y group was significant. An extensive series of observations was undertaken by Ritchie⁴ in 1916 in order to determine the degree of agglutination occurring with the serum of normal persons. He investigated the serum of 792 men and women, none of whom, as far as they were aware, had suffered from dysentery. Ritchie used suspensions of living organisms in his experiments, incubated the mixtures of organisms and diluted patient's serum in air at 37° C. for two hours, the result being read off on the microscope stage, using a $\frac{3}{8}$ in. objective. He found that 4.6 per cent. of the cases examined agglutinated the Shiga organism at 1 in 64, and considers that complete agglutination in a dilution of 1 in 64 and above should be regarded as diagnostic. With *B. dysenteriae* Flexner he found that 30 per cent. of the cases examined gave agglutination at a dilution of 1 in 128, and concluded that complete agglutination in a dilution of above 1 in 128 should be looked upon as diagnostic, but in a dilution of 1 in 128 or lower cannot be relied upon for diagnostic purposes.

Our experiments on the serum of 214 normal persons differed from those of Ritchie in several important respects:

1. Dreyer's standard agglutinable cultures, selected on the grounds of their relative insensitiveness to the serum of normal persons, were used.

2. The standard agglutinable cultures used were formalized, which reduces considerably the agglutinability of dysentery bacilli.

3. The macroscopic method, as recommended by Dreyer, was used.

Using this different technique we found that 10 per cent. of the persons examined contained 5 agglutinin units, 8 per cent. contained 7 agglutinin units, and 2½ per cent.

contained 10 or more agglutinin units to *B. dysenteriae* Flexner. The figures for *B. dysenteriae* Shiga were as follows: 3.3 per cent. contained 5 agglutinin units, 2.8 per cent. contained 7 agglutinin units, and 2 per cent. contained 10 agglutinin units.

Our results, set out in the preceding tables, confirm those of Dreyer, and indicate that, using his method, the presence of 10 or more agglutinin units per cubic centimetre of serum is, for all practical purposes, diagnostic of an active bacillary dysenteric infection caused by the bacillus agglutinated, and that the presence of 7 units is highly suspicious of dysenteric infection. The error introduced on account of the reaction of the serum of normal persons to the standard agglutinable cultures used amounts to 2½ per cent. in the case of *B. dysenteriae* Flexner, and to 2 per cent. in the case of *B. dysenteriae* Shiga infections.

Our group of cases due to infection by *B. dysenteriae* Shiga is small, but it is to be noted that in every case of proved Shiga infection the patient's serum agglutinated the standard agglutinable culture used, and this agglutination was always complete in the highest dilution of the patient's serum tested. As far as our observations go, the results indicate that in the case of infections due to *B. dysenteriae* Shiga determination of the agglutinin content of the patient's serum constitutes a valuable method of diagnosis.

This is, however, far from the case with patients infected by members of the mannite-fermenting group of dysentery bacilli. We tested the serum from 151 cases of dysentery from whose stools bacilli of this group had been isolated, and found that in only 58 did the patient's serum contain 10 or more agglutinin units, that is, less than 40 per cent. of the persons who had recently been infected by a member of the Flexner-Y group exhibited an agglutinin content in the serum of 10 or more units. The low proportion observed might have been due to the fact that in many patients the infection was very mild and the agglutinins produced so small in amount that they were not demonstrable; but in the light of the well ascertained fact that there is a family of mannite-fermenting dysentery bacilli, it appeared more likely that some patients had been infected by one member of the group and others by another.⁶ That this latter view is the correct one is suggested by the results of the experiments set out below, which were carried out to investigate this point.

Three strains of *B. dysenteriae* Flexner which had been isolated during this year's epidemic were grown on ordinary nutrient agar for eighteen hours, the growth washed off and emulsified in normal saline, and formalin added to make a concentration of 1 per cent. The formalized emulsions were placed in an ice chest for a week. At the same time a similar formalized emulsion was made from a strain of *B. dysenteriae* Flexner which we obtained from the Lister Institute, and also an emulsion of *B. dysenteriae* Y, which we obtained from the same source.

The agglutinating power of the serum of 40 patients, from the stools of each of whom mannite-fermenting dysentery bacilli had been isolated, was determined against each of the above emulsions and also against Dreyer's standard agglutinable culture (Flexner). The patient's serum was tested at dilutions of 1 in 20, 1 in 40, and 1 in 80 against each of the above strains of *B. dysenteriae* Flexner. It is not possible, of course, to express the results obtained in terms of standard agglutinin units.

In addition to the above series of 40 "positive Flexner" cases, a second series of serums from 40 normal persons was examined in precisely the same way. The mixtures of diluted patient's serum and dysentery emulsions were heated to 55° C. for four and a half hours, and read from fifteen to thirty minutes afterwards.

The "Y" strain used was a direct descendant of Hiss and Russell's original "Y." On being tested against forty samples of normal serums it was found to give standard agglutination at a dilution of 1 in 40 or over in 13 cases—that is, in 32.5 per cent. The figures obtained for this "Y" emulsion have accordingly been excluded from the tables given below, in which the results of these experiments are expressed.

TABLE V.—The Agglutinating Power of the Serum of 40 Patients from whose Stools *B. dysenteriae* Flexner had been recovered, Tested against Five Different Strains of *B. dysenteriae* Flexner.

Dysentery Emulsion Used.	Number giving Standard Agglutination at 1 in 20 or over.	Per cent. giving Standard Agglutination at 1 in 20 or over.	Number giving Standard Agglutination at 1 in 40 or over.	Per cent. giving Standard Agglutination at 1 in 40 or over.
Dreyer's standard agglutinable culture	19	47.5	16	40.0
Flexner (Lister Institute)	20	50.0	11	27.0
No. 16	18	45.0	15	37.5
No. 65	15	37.5	10	25.0
No. 86	19	47.5	10	25.0

TABLE VI.—The Agglutinating Power of the Serum of 40 Normal Persons Tested against Five Different Strains of *B. dysenteriae* Flexner.

Dysentery Emulsion Used.	Number giving Standard Agglutination at 1 in 20 or over.	Per cent. giving Standard Agglutination at 1 in 20 or over.	Number giving Standard Agglutination at 1 in 40 or over.	Per cent. giving Standard Agglutination at 1 in 40 or over.
Dreyer's standard agglutinable culture	3	7.5	1	2.5
Flexner (Lister Institute)	1	2.5	—	—
No. 16	4	10.0	3	7.5
No. 65	4	10.0	3	7.5
No. 86	2	5	—	—

Of the 40 positive serums tested (Table V)—

- 11 failed to agglutinate any of the 5 emulsions used;
- 29 agglutinated one or more of the 5 emulsions used;
- 2 serums agglutinated all 5 emulsions;
- 4 serums agglutinated 4 emulsions only;
- 3 " " " 3 " " "
- 7 " " " 2 " " "
- 13 " " " 1 " " "

Of the 13 serums which agglutinated one strain only—

- 4 serums agglutinated Dreyer's standard agglutinable culture only;
- 3 serums agglutinated No. 16 only;
- 3 serums agglutinated No. 65 only;
- 3 serums agglutinated No. 86 only.

Reference to the figures given in the two preceding tables shows that of the five strains of *B. dysenteriae* Flexner used, Dreyer's standard agglutinable culture gives the most satisfactory results. Yet, even when this strain is used, only 40 per cent. of the cases, from each of which dysentery organisms of the mannite-fermenting group had been recovered, gave a positive result. If the patient's serum is tested against a number of strains, the number of cases giving a positive result increases.

Patient's serum tested against:	Number giving Standard Agglutination at 1 in 40 or over.	Per cent. giving Standard Agglutination at 1 in 40 or over.
Dreyer's standard agglutinable culture only	16	40.0
Dreyer's S.A.C. and Flexner (Lister Institute)	17	42.5
Dreyer's S.A.C. and Flexner (Lister Institute) and No. 16	22	55.0
Dreyer's S.A.C. and Flexner (Lister Institute) and Nos. 16 and 65	26	65.0
Dreyer's S.A.C. and Flexner (Lister Institute) and Nos. 16, 65, and 86	29	72.5

S.A.C. = Standard agglutinable culture.

That is, if the serum of patients who have recently suffered from infection by a member of the Flexner group of dysentery organisms be tested against five strains of the group, the percentage giving a positive result is nearly twice as great as the positive findings when only one strain is used; and it is reasonable to suppose that the number

yielding a positive result would be still further increased if the patient's serum were tested against a still greater number of locally isolated strains.

In conclusion we express our indebtedness to Captain B. G. Klein, R.A.M.C., medical officer in charge of the dysentery wards, for his kind co-operation.

POST-OPERATIVE PULMONARY EMBOLISM DUE TO THE CONDITION OF THE BLOOD.

BY

A. LAPHORN SMITH, M.D., M.R.C.S.ENG.,

FORMERLY SURGEON-IN-CHIEF OF THE SAMARITAN HOSPITAL FOR WOMEN, MONTREAL.

OPERATING surgeons all over the world are greatly indebted to the writers of the two very interesting articles on post-operative thrombosis and embolism which appeared in the *BRITISH MEDICAL JOURNAL* on March 9th and 23rd. With every word in these two articles I most heartily agree—with one exception, and that is, instead of putting the quality of the blood last on the list I would put it first.

Early in my professional career I came under the influence of Sir William Hingston, who pointed out to me the great demands of the human system for water. The kidneys, the skin, the bowels, and the lungs are all calling for it to enable them to carry on their functions. These apply equally to men and women, but in the case of nursing women lactation makes a large additional demand. Some years later I listened for an hour to the scholarly presidential address of Dr. Mathew D. Mann of Buffalo before the American Gynecological Society, in which he pointed out that many of the aches and pains from which women suffered would not have afflicted them if they had been water drinkers. Since then I have seen many women operated on at the Mayo Clinic for gall stones who would never have had them if their bile had not been a super-saturated solution of biliary salts, ready to throw down crystals on the slightest pretext; and I have removed in women many stones from the kidneys and ureters which were due to supersaturation of the urine with solid matter that would never have been formed if the specific gravity of the urine had been kept down. Early in my career as an abdominal surgeon, as well as in consulting obstetrics, I came to the conclusion that the tragic deaths from pulmonary embolism, which at that time were much more frequent than they are now, both after operations and confinements, were due principally to a hyperfibrinous condition of the blood, and all these years I have taken great and laborious pains to see that all these patients were allowed to drink freely.

To this fact more than to anything else do I believe that it is due that I have not yet seen a death from pulmonary embolism following any of my own operations, nor after any of the confinements that I have attended.

The other factor is one to which Colonel Symonds has done a service by calling attention. He says: "Is it necessary to keep the parturient woman on her back for days together?" From his experience after abdominal operations he is inclined to think that early movements of the limbs and frequent changes of position would diminish the number of cases of embolism. My answer is that not only is it not necessary, but positively harmful. The heavy uterus falls backwards and ceases to drain; adhesions form between the ends of the tubes and the peritoneum, and the woman is sometimes never quite well again. We should not only permit, but even urge, the patients to have their position changed frequently during the first few days and to move their limbs freely as soon as they are able to do it themselves. I have always told women after confinement to lie any way they like—right side or left side, or even on the face—rather than on the back. Most important of all is it to sit up on a chamber in bed three or four times a day to pass water and move the bowels.

Sir William Hingston, who knew the habits of the Iroquois Indians thoroughly, told me that they were almost absolutely free from the accidents of childbirth common to their white sisters, which he attributed to their not going to bed at all, but continuing the march with the papoose on their back after a few hours' rest.

The only cases of pulmonary embolism in which I have been even remotely interested occurred in the wives of two medical friends in other cities who had had ideal confinements and afebrile recoveries, and yet who died without any warning on the twelfth and fourteenth days at the moment when life seemed at its happiest; another in the wife of a lay friend, who made a perfect recovery, and died suddenly on the fourteenth day. As Colonel Symonds points out, the nurses trained twenty years ago are in favour of the dorsal position for ten days and very little movement; and I may add they were bitterly opposed to the patient being allowed cold water or fresh air for fear of a chill, and sunlight for fear of ophthalmia neonatorum. Our nurses trained to day are taught that air, water, and sunlight are the great enemies of microbes, and that chills mean fever due to microbic infection. A closed and darkened room generally means a hot room, causing profuse perspiration, which, with lactation, would make the blood less liquid and more liable to clot in the veins. Lying on the back for ten days, with the blood getting daily more clottable, is a very good way to bring about thrombosis and death by embolism when the patient begins to move about.

While it is important to carry out all the suggestions of Dr. McCann and Colonel Symonds, I feel sure that some other factor has been operating silently in their favour, and that is that doctors are urging women to drink water, and nurses are more and more getting in the way of allowing them to do it. It must be in the experience of every accoucheur that what every woman craves for most is a drink, cold preferred. Elderly women who have had large families have assured me that the most unpleasant part of their confinement was the awful ten days of immobility on the back, and, next to that, the thirst. Medical friends who have been operated on have assured me that their greatest desire was a drink of hot tea, and acting on their suggestion I always prescribe it as soon as the patient comes out of the anaesthetic, whether they are vomiting or not. If the first cupful comes up it at least washes out the stomach.

Getting up several times a day to answer the calls of nature will not only ensure drainage of the uterus and vagina, but that and sitting up in bed for meals will prevent the stagnation of the blood, which Colonel Symonds points out is one of the factors in thrombosis. Many practitioners fear to allow the patient to sit up on a chamber for fear of all kinds of things happening—that the uterus may drop out of the body, that it may drop inside out, becoming inverted, or that there will be tremendous haemorrhage; but these are all bogies.

Another friend, Joseph Price, who was assistant to Lawson Tait, told me that he always placed his patients on their right side with their knees drawn up after abdominal sections, and as soon as they were able he allowed them to move about freely in bed, and to stretch and bend their legs frequently. Lawson Tait's idea was to relax the tension on the abdominal stitches, which were silkworm gut and through-and-through.

Pulmonary embolism is fortunately very rare, only 47 deaths having occurred from it at the Mayos Clinic in 63,000 operations. In former days, when the accident was more frequent, it was the custom to prepare the patient by drastic hydragogue catharsis for a day or two before. Then, again, haemorrhage was more frequent and more abundant; also the operating rooms were kept at 80°, so that the patient lost a large amount of water by the skin, while vomiting from the anaesthetic prevented replacement of the lost water. For this last reason I believe that the chances of embolism would be greatly lessened if a rectal enema were given by the slow method at the rate of 20 oz. of beef-tea or salt solution for every half-hour the operation lasts. If given at a temperature of 105° F. it would practically do away with shock and sub-normal temperature. I constantly resorted to it while in charge of Lady Wemyss's Hospital in France, with great benefit, as I reported in this *JOURNAL* two years ago, and I am glad to see by recent reports that it is being more

generally used in the hospitals over there. The reservoir should lie on the foot of the bed or operating table with the patient in the inverted position, so that the water has a fall of only a few inches from the reservoir to the rectum.

Conclusions.

1. Have the full normal proportion of water in the blood before operating.
2. Replace by the rectum the amount of liquid lost by vomiting, catharsis, sweating, haemorrhage, and urine, either during the operation or immediately after it.
3. Encourage the patient to move the lower limbs freely, if not during the first two days at least during the next ten.
4. Give the patient abundance of water between meals and during the night; it may be hot or cold, sweet, sour, or salty, in the form of lemonade, barley water, weak tea without milk, or beef-tea; a jug and drinking cup with spout should be left within reach so that it may be taken when wanted without waiting for the nurse to come.
5. Speedy operating lessens embolism because it means less haemorrhage, and less sweating and less loss of water from the system.
6. Round-pointed needles with flat eyes are much less likely to cause haemorrhage than ones with cutting edges, and should alone be used in the abdomen.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF ORIENTAL SORE.

AMONGST Indian troops in Mesopotamia, between the months of November and March, it is common to find sores which are chiefly distributed on the extensor aspect of the limbs and face. These sores are characterized by an irregular spreading raised edge, which is often undermined, vascular, and anaesthetic; by a base formed of pale oedematous granulations, slimy in appearance and slightly purulent; and by the chronic condition of the lesions, which may take months to heal. A crust often covers the sore, and at a hasty glance may be mistaken for a dry scab. On pressing the scab beads of pus appear at its edges. The sores are found to contain *Leishmania tropica*, chiefly situated in the undermined edge. They have been treated with hot fomentations, dilute carbolic and mercurial lotions, pure carbolic acid, powdered potassium permanganate, eusol, eupad, and injection with kerosene oil, with merely palliative effect.

The following method of treatment, employed in the ulcerating stage, was originated by Major W. R. J. Scroggie, I.M.S., who has kindly given me permission to publish the results. It has been in use during two winter seasons in a considerable number of cases.

Any undermined edge is cut away, and the surface of the ulcer is cleaned with carbolic lotion, and, if necessary, fomented to remove crusts and discharge. It is then covered with powdered corrosive sublimate obtained from the blue 8½-grain tablet. It is necessary to powder especially at or under the edge, where the chief infection lies. Care must be taken that the surrounding sound skin is free of powder. A dressing of dry gauze is then applied. Two hours later a hot fomentation is applied, and another at the end of two more hours. For the next two days hot fomentations twice a day are used until the sore presents a clean, bright red, vascular base, with a level or slightly sloping edge. The effect of the perchloride is to permeate every interstice of the wound, and in particular to destroy the infected margin. A short time after its application considerable pain ensues, which may last for twelve hours, but is not sufficient to require morphine. It is necessary to watch the temperature, as occasionally a dry blue scab is formed with pus pent up beneath. This must at once be raised to give exit to discharge. As a rule, fomenting keeps the surface sufficiently moist to allow of drainage of pus. When the surface of the wound is clean, new skin extends from the edges, and gradually covers the wound surface. With a daily dressing of 1 in 2,000 perchloride solution or eusol uninterrupted healing occurs, the time taken depending upon the size of the ulcer and varying from twelve days to six weeks. The scar is smooth and level with the surrounding skin, unlike the raised and

thickened scar produced by the use of antimony tartrate ointment.

If the above treatment were systematically carried out from the time of diagnosis, it is possible the length of absence of patients from their units would be materially shortened. In civil life these sores may be borne with little discomfort and interference with daily work, but in the exigencies of military service they form a real cause of ineffectives and their prolonged stay in hospital.

W. S. EVANS,
Captain R.A.M.C. (Temp.).

PERSISTENT VITELLINE DUCT IN TWINS.

Mrs. C. was delivered of female twins on April 5th, 1913. The first was a footling, the second a vertex, presentation. There was one sac of membranes. A troublesome prolapse of the cord in the first case may possibly account for the difference in degree of the two cases.

In appearance there was nothing unusual about the cords, which were dry and off on the ninth day. On the tenth day a few drops of bile were observed on the pad of the first born, continuing daily at that amount morning and evening. No faecal matter appeared. The stump of the cord, which was dry and firmly healed, presented in the mesial line, subcentrally, a well marked triangular orifice, which would take a No. 3 catheter. The intestinal orifice must either be very small or protected by a valvular position.

Three days afterwards there was a minute trace of bile on the pad of the later twin, and the umbilicus showed an even more manifest orifice situated similarly.

There has been no constitutional disturbance, but a slight degree of icterus has been present all through in both cases.

In Norris and Dickinson's *Textbook of Obstetrics*, vol. i, p. 118, it is stated that:

The connexion of the yolk-stalk or vitelline duct with the intestinal canal rapidly becomes less conspicuous, and by the end of the fifth week the yolk-stalk has but slight connexion with the gut. The position of the juncture of the vitelline duct with the intestinal tract varies greatly, but usually corresponds with a point within the small intestine from 40 to 60 centimetres (16 to 24 inches) from the ileo-caecal valve. When the usually atrophic cord is replaced by a tubular recess, the persistent portion of the duct constitutes Meckel's diverticulum, a structure of interest. The vitelline duct may remain pervious throughout its intra-embryonal extent, resulting sometimes in congenital umbilical fistula.

That the condition should occur in twins must be uncommon, but not to be marvelled at when one calls to mind that these are likely to be homologous twins, so that the vitelline ducts of each developed from common parent blastodermic cells, and inherited in equal degree the tendency to persist.

THE TREATMENT OF PERNICIOUS ANAEMIA.

I THINK it may be of interest to record a case of pernicious anaemia treated by intramuscular injections of salvarsan cream. My patient, a woman aged 39, had suffered from pernicious anaemia, showing all the usual blood changes and general signs and symptoms, for over two years. In spite of several temporary remissions the disease steadily progressed, and in November last she appeared to be dying. The liver reached to the umbilicus, and there was a loud haemic murmur over the heart. The usual blood changes were present and the haemoglobin content 15 per cent. I gave her an injection of 0.2 gram salvarsan cream (prepared from "Kharsivan" brand salvarsan by Messrs. Allen and Hanbury) into the muscle of the buttock (as suggested in the *BRITISH MEDICAL JOURNAL* in 1912 and 1913), repeating the same dose in a fortnight, and another of 0.3 gram a fortnight later. The result was really extraordinary. Within a few weeks she regained her usual healthy colour, the liver returned to its normal size, the haemic murmur disappeared, and the haemoglobin content rose to 85 per cent. She is now, six months after commencing the injections, apparently in normal health. Whether the recovery is permanent I cannot say, but a line of treatment followed by such remarkable results in such a hopeless disease is worth recording, and I hope that this brief note will lead to its further trial.

Reports of Societies.

THE ROLANDIC AREA IN THE INSANE.

THE ordinary quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland was held on May 28th, when Lieut.-Colonel D. G. THOMSON, R.A.M.C., was in the chair. Dr. JOHN TURNER gave an account, illustrated by a number of fine drawings, of researches into the Rolandic area in the insane. The anterior lip of the fissure of Rolando, that part of the cortex termed ascending frontal, was characterized, histologically, in its upper two-thirds by the presence of very large nerve cells which, from their size and the peculiarities of their structure, lent themselves readily to the study of pathological changes. Physiologically, this region represented the chief executive station of the brain—that whence the greater part of the nervous currents passed on their way from the brain to the muscles. Insanity was not only disorder of motive in conduct, but also disorder in execution, as was vividly exemplified in dementia praecox, though all forms of mental disorder were characterized by mannerisms and affectations of speech and behaviour. He thought it probable that if there were anatomical changes in insanity they would show themselves in this region. He had been impressed with the peculiar form of Betz cell found in the brain of the insane, and in 1914 compared the picture as seen in the cortex of the insane with that in a corresponding area from a series of brains of persons dying in two large London hospitals. In the cases from the ordinary hospitals he found the prevalence of what might be called the insane type much less marked. He now presented a study of the configuration and micrometry of the cortex in the Rolandic area for the purpose of ascertaining whether there was deficiency or atrophy in the depth of any of the laminae in the different forms of insanity. A further object was to ascertain whether the particular form of Betz cell described was maintained in the areas controlling the muscles of the remaining part of the lower extremities, of the upper extremities, or of the face. In addition, he attempted to correlate differences in the internal structure of the Betz cells with symptoms. Having described in detail the technique employed, he divided the cases which he had examined into three classes: (1) All cases of acquired insanity, (2) cases of dementia praecox, (3) imbeciles, whether suffering from epilepsy or not. The second class he particularized; dementia praecox he regarded as denoting more a temperament than a disease, including therein inefficient of all kinds, not alone those within asylum walls, but all whose nervous system was of deficient durability and therefore liable to break down under comparatively slight stresses. Though some of these persons made a decent livelihood, and some seemed to be of quite average ability, they yet possessed what Adolf Meyer termed the hall-mark—namely, a constitutional inability to meet their difficulties in an adequate manner. He set out his conclusions under the following four heads:

1. Anomalies in the form of the Rolandic fissure, and in the arrangement or architecture of its cortex, occurred more frequently among the insane, especially among subjects of dementia praecox, and imbeciles, than in normal individuals.
2. There appeared to be distinctive characters in the two sexes.
3. Micrometric studies indicated sexual differences in the width of the laminae; they failed to afford any clue to a solution of the problem of the pathology of insanity.
4. A study of the Betz cells he believed to be of very real assistance in the matter. The undue proportion of the axonal type in the insane enabled a glimpse to be obtained of the anatomical basis in a large number of cases. He regarded this type of cell as one of defective structure, and probably of deficient durability, and that the evidence favoured the view that it was an innate defect due to arrested development. The presence of this type in greater or less number he regarded as a rough index of the stability of any given brain; other things being equal, a brain with a high percentage of these cells would more readily break down than a brain with a low percentage. On this view, the brain of the precocious dement

was the most unstable of all, and, relatively, more so in females than in males. This he considered to be in accord with clinical experience.

Reviews.

RADIO-THERAPEUTICS.

THE second volume of the new edition of KNOX's book on *Radiography and Radio-Therapeutics*¹ deals with the second subject. The general arrangement is practically the same as in the first edition, but the 130 pages of that edition have been extended to slightly over 200, and a large number of illustrations added. An introductory chapter deals mainly with the action of radiations upon tissues, both normal tissues and morbid growths; it is illustrated by a series of photomicrographs which demonstrate very fully the changes produced by both x rays and radium.

In discussing the question of the so-called "selective action" of radium on cancer cells the author suggests that the word "selective" is badly used, and points out that all living cells are influenced in varying degree according to the resistance of the particular cell in question. Thus, young and actively growing cells are more readily influenced than mature cells, and cells of new growths approximate in structure and power of resistance to the actively growing cells of a tissue. "Selective absorption" of radiations by the tissues is a better term, and this is applicable to all forms of radiation.

The dangers attendant on the use of x rays and radium are discussed under the headings of acute and chronic dermatitis, late manifestations, and sterility, with reference both to operators and to patients. We are fully in agreement with the suggestion that there is a possibility of danger to an operator from the secondary radiations from the protective materials applied to his own person. The ordinary x -ray proof gloves worn on the hands of those workers who have already had some amount of dermatitis may be a source of danger rather than protection.

The chapter on x -ray therapeutics is comprehensive. Starting with a description of methods of protection, the necessary x -ray generating apparatus is described in detail, and following this is a very useful and full account of the various methods of estimating dosage. Filtration is an important subject; the writer expresses his conviction that the results obtained when using aluminium filters have been better than with boiler felt or other materials. An interesting table of the comparative values of different filters is given.

The various conditions—skin, growths, uterine fibroids, and so on—in which x -ray treatment is indicated are set out, and the application of the method to ringworm is well described and illustrated. In discussing the x -ray treatment of exophthalmic goitre the opinion is expressed that it should have a trial in all cases, even when operation is contemplated; but in, at any rate, the acute cases it must be combined with rest in bed, dietetic and drug treatment.

Phillips is responsible for the description of the physics of radium in a chapter which is simple, easy to understand, and practical. The preparation of radium emanation, and the manner in which this slowly decays in strength, are especially good.

This is followed by a chapter on the practical application of radium to disease and the various methods of using it, and the forms of applicators indicated in various conditions and sites. The illustrations of this chapter are valuable. The combined use of radium and x rays in the treatment of malignant disease gives the author an opportunity of contrasting the possibilities of the one and the other. It is suggested that in some instances it is advantageous to alternate their use. The war has been responsible for an additional chapter, and Cole's work on the value of radiations in the plastic surgery of the face and neck is very striking. The cases of keloid scars following on bad wounds of the face and neck show, as is demonstrated by many illustrations, very remarkable cosmetic results.

¹ *Radiography and Radio-Therapeutics*. Part II. *Radio-Therapeutics*. By Robert Knox, M.D. Edin., M.R.C.S. Eng., L.R.C.P. Lond. Second edition. London: A. and C. Black, 1918. (Sup. roy. 8vo, pp. 387 to 606; 100 figures, 15 plates. 15s. net.)

Dr. Knox is to be congratulated as having produced a book far in advance of any other which has appeared on these subjects. The letterpress is clear and concise, and practical to the last degree. Nothing of any importance has been omitted. The many illustrations, without exception, are very fine and well chosen. As a whole—that is, the two volumes together—it should remain the standard textbook in the English language for many years to come, useful alike to medical practitioners, to specialists in x-ray and radium work, and to students.

MEDICAL DISEASES OF THE WAR.

As anticipated in the review of Dr. A. F. HURST'S *Medical Diseases of the War*² in our issue of March 17th, 1917, a second edition has soon been required, but the present volume is much more than a revised edition, for it is over twice the size, and has increased correspondingly in price. The original chapter on war neuroses has been expanded into eleven, and as Part I of the work occupies nearly half the volume. These chapters show the author's growing experience at Netley and elsewhere, especially as regards the difficult subject of treatment; they now contain a classification of functional disorders in soldiers which it was previously considered inadvisable to attempt. Clearly and attractively written, this work breathes the atmosphere of practical experience and accurate thought, and at the same time the conclusions of Crile, Mott, Buzzard, and others are brought before the reader. Babinski's condemnation of the doctrine of hysterical stigmata, such as anaesthesia and restriction of the field of vision, which he considers are always due to suggestion by the examining medical man, is endorsed by Dr. Hurst. While admitting the existence of Babinski and Froment's reflex paralysis, he considers that the distinction between it and hysteria is much less clearly defined than these authors assume; thus, at first the symptoms may be reflex but subsequently become hysterical from auto-suggestion, and further, some cases of reputed reflex paralysis may be really local tetanus.

The use of hypnotic suggestion is fully discussed, but its limitations are indicated, and it is admitted that it is generally not the most satisfactory treatment for hysterical contractures, gaits, or speech defects. In the diagnosis between organic and hysterical or simulated deafness almost all the tests formerly recognized have been discarded, the only criterion regarded as trustworthy being the presence of normal vestibular reactions in hysterical deafness and their loss in the organic form.

The new chapter on tetanus contains a good account of the localized form, of which head tetanus was the only variety recognized before the war. A fatal case of anaphylaxis due to injection of antidysenteric serum is mentioned, and with regard to its prevention in the serum treatment of tetanus Besredka's plan of giving it under general anaesthesia is recommended. It is interesting to note that Major Hurst does not consider that in diminishing the exaggerated reflex excitability of the central nervous system in tetanus magnesium sulphate has any advantages over drugs, such as chloroform, which have none of the dangers attending the injection of the magnesium salt.

Although malaria played such an important part in the Salonica campaign it is not specially considered, but perhaps this may be a feature of a further edition which may be confidently predicted for this excellent work.

NOTES ON BOOKS.

*Hints for R.A.M.C. Officers*³ is a modest little work which many newly joined medical officers will find helpful during the first few weeks of army life. The main duties of a medical officer in charge of troops at home are clearly indicated, and useful guidance is given through the maze of army technicalities and regulations as to correspondence and reports. We have seldom seen so many misprints, or such an elaborate index, in so small a work. Under the heading of "kit," we note with amusement that "the greatcoat has been suspended for the duration of the war."

¹ *Medical Diseases of the War*. By Arthur F. Hurst, M.A., M.D. (Oxon.), F.R.C.P., temporary Major R.A.M.C. Second edition, revised and enlarged. London: Edwin Arnold. 1918. (Demy 8vo, pp. 319; 6 figures. 12s. 6d. net.)

² *Hints for R.A.M.C. Officers*. By Ramcorps. Edinburgh: W. Bryce. 1918. (5½ x 4½ in., pp. 56. 1s. net.)

Any sound guide to exposure of the deep vessels by safe routes which give ample access, will be welcome to all war surgeons, not only those who need to make such incisions for dealing with actual haemorrhage, but also those at the base hospitals who have to operate upon arterial haematomata and aneurysms. MM. FIOLE and DELMAS have written a little book⁴ up at the front and have found on the spot an artist to enhance the value of their descriptions. The authors have by no means lost reverence for Farabeuf and indeed are not trenching on his preserves, for he gave us the classical directions for ligature of sound vessels in their continuity; they are dealing with the exposure of bleeding vessels in the midst of infiltrated, blood-obscured tissues, and offer a means of isolating the very bleeding point without undue damage to intervening structures, in such a way that blind grasping of a bleeding area in forceps—which has befallen every one to his discomfort—shall be unnecessary even in emergency. It is not to be thought that even the modes of access here suggested are simple, and it is certain that they should be practised on the cadaver, to ensure freedom in their employment at the moment of need. The book is to be heartily commended for general study forthwith.

⁴ *Découverte des Vaisseaux Profonds par des Voies d'Accès Largues*. By J. Fiolle and J. Delmas, Chirurgiens à l'Automobile Chirurgical, 21, Paris: Masson et Cie. 1917. (Demy 8vo, pp. 128; 34 figures. Fr. 5).

THE MEDICAL PROFESSION UNDER THE MILITARY SERVICE ACT.

In our last issue (p. 622) we gave a short account of the regulations which have been made with regard to applications concerning medical practitioners for exemption from military service, and of the procedure contemplated under these regulations. By the time these words are in print it is expected that an explanatory statement by the Ministry of National Service will be in the hands of every doctor now in civilian practice. In the meanwhile we have received various inquiries from medical men who are in doubt as to how they stand. Our reading of the position is broadly as follows:

Every doctor of military age will be approached in the first instance by the Ministry of National Service, which will offer him a "certificate of protection" from military service under the conditions stated in the proviso to Regulation 24 (see BRITISH MEDICAL JOURNAL, June 1st, p. 622, second column). If he is not satisfied with the terms of this certificate he may, within fourteen days of receiving notice from the Ministry, lodge an application for exemption with the appropriate medical tribunal (the Central Medical War Committee, and the Scottish Medical Service Emergency Committee have been recognized as Medical Tribunals). The tribunal will in due course hear his case and adjudicate on it, giving him four clear days' notice of the hearing. The tribunal may refuse exemption from military service, or may grant absolute, temporary, or conditional exemption. Where the ground of exemption is occupational the tribunal will be enabled to grant conditional exemption only, the condition being that the doctor, if not required for medical service with His Majesty's forces, shall give his service to the civil community in such manner and under such conditions as the Minister of National Service, after consulting the appropriate professional committee, deems best in the national interest. The principles by which the Committee of Reference will be guided may be gathered from the terms of the communication from it printed below.

An appeal may be allowed to the Central Tribunal (the general tribunal for the whole kingdom) from the decision of the medical tribunal (or the Committee of Reference) on any application on personal grounds—that is, on the grounds of serious hardship, of ill health or infirmity, or of conscientious objection. But such appeal may be made only with the leave of the medical tribunal or on the recommendation of the Committee of Reference.

The usual form of exemption granted by a medical tribunal will be subject to the conditions laid down in the proviso to Regulation 24. But since the protection certificate issued by the Ministry of National Service will be subject to the same conditions, the position of a doctor who has accepted a protection certificate and of one who, having made application to the medical tribunal, has received conditional exemption, will, in the majority of cases, be the same.

From this point onwards the central professional committee ceases to act as a statutory tribunal, and becomes an advisory body to the Minister of National Service respecting the use to be made of those doctors who have received either conditional protection or conditional exemption as the case may be. The country will be investigated area by area, the local committees assisting the central committee. A doctor who is not satisfied with the duties proposed to be assigned to him will have a right to be heard by the central committee, just as an enrolled man has had in the past, and the grounds of objection will presumably be much the same as those which have been held to be valid in the past, though they are not, and never have been, precisely defined.

With regard to the terms and conditions of substitution medical service, we understand that this is receiving close consideration. It is obvious that no effective procedure can be laid down until the financial basis has been settled. The question has been asked: To what body could a doctor apply for liberation if his health broke down in substituted practice? The only answer seems to be that those who put him there must be responsible—namely, the Ministry of National Service—in consultation with the medical tribunal, and in concert with any Government department concerned. This, and many other points, will have to be settled at an early date.

In a circular (R. 196) addressed by the Secretary of the Local Government Board to the Central Medical War Committee, the Committee of Reference, and the Central Tribunal, dealing with the new regulations, special reference is made to Regulation 24, which provides that any exemption on the grounds of occupation shall, and any exemption on personal grounds may, be conditional on the medical practitioner undertaking professional service under conditions laid down by the Director-General of National Service after consultation with the medical tribunal, and in concert with any Government department concerned. Upon this the circular says:

The demand for medical practitioners for military and civilian service is so great that it is only by a carefully considered distribution of the available medical men that the requirements of the country can be met. This has been recognized by the medical profession itself in resolutions passed by their representatives. It is because of this special position of the medical profession that the provision referred to above has been made; and it is because of this special position, also, that the profession is granted a special tribunal drawn from its own members.

The President of the Local Government Board is assured that the regulation in question will be administered with the utmost consideration consistently with the national interests, and that any arrangements under it will be made in full consultation with the medical tribunal. The circular concludes as follows:

Mr. Fisher realizes that the task before the medical tribunal and the Committee of Reference is a formidable one, but their members have already gained wide experience in the work. The country generally, and not only the medical profession, are indebted to them for their services; and it is noteworthy with what general satisfaction the performance of these services has been received. They are justified, therefore, in approaching with confidence the work which lies before them.

With regard to applications concerning medical practitioners made to ordinary local appeal tribunals which were pending at the date (May 23rd) when the regulations for medical men came into force, it is provided that if the case has already been referred to the professional committee and a recommendation has been made, it shall be decided by the appropriate medical tribunal in accordance with the previous regulations. If, however, a recommendation has not been made, the case is to be referred to the medical tribunal, to be decided as if it were an application under the new regulations.

In a memorandum (R. 198) issued to ordinary local and appeal tribunals, the Local Government Board points out that such tribunals will not in future deal with any application concerning a medical practitioner, whether an original application for a certificate of exemption, or an application for the renewal or review of a certificate already granted. Such applications are to be made directly to the appropriate medical tribunal, in accordance with the special regulations relating to medical practitioners.

REDISTRIBUTION OF HOSPITAL STAFFS IN LONDON.

We have received from the Committee of Reference the following notification as to action proposed to be taken by the Minister of National Service:

The Minister of National Service has approved a recommendation of the Committee of Reference that, in order to provide more doctors for service in the army whilst at the same time safeguarding the interests of the civil community, the hospitals in the London area shall be arranged in groups and that a sufficient staff of doctors shall be reserved to maintain the medical service of each group.

It will be recognized that many physicians and surgeons are now serving at hospitals in various parts of London involving long journeys, waste of time, and, consequently, loss of energy, and that at the same time there are others both of military age and over that age who are capable of doing and willing to do more hospital work than they are now doing.

It is proposed in the first place to ask every member of the staff of a hospital to supply the Committee of Reference with a detailed statement of the hospital work and other work of a national character which he is now fulfilling, on a form which will be sent him for the purpose. This information will be tabulated and an analysis made of the amount of service rendered by each member of a hospital staff. From this analysis the Committee will be in a position to advise the Minister of National Service as to the number of doctors of military age who must be considered indispensable to the civil community, and who should in consequence be retained in civil practice.

It may be necessary, in order to obtain the fullest benefit of a doctor's service, to transfer his work from a hospital in one group to a hospital in another group, as a temporary arrangement for the duration of the war, and for this reason each doctor will be asked to sign a declaration that if it is considered desirable in the national interest, he will agree to serve on the staff of any hospital or hospitals to which he may be assigned by the Minister of National Service on the recommendation of the Committee, and at the same time to discontinue his services at any hospital where he may now be acting as a member of the staff.

An appeal will be made to those members of hospital staffs who are over military age, to those who hold *a la suite* commissions in H.M. army, and to those who have been medically rejected for service in the army, or are otherwise excepted from liability under the Military Service Acts, to assist by their co-operation in making this scheme a success.

It is recognized that the reorganization of the medical staffs may cause inconvenience to the governors and officials of the various hospitals, but it is not intended that any alterations of staff shall be proposed beyond those considered by the Minister of National Service on the advice of the Committee to be absolutely essential in the national interests.

Addresses.

The address of the Medical Tribunal for England and Wales is 429, Strand, London, W.C.2, and for Scotland the Royal College of Physicians, 9, Queen Street, Edinburgh. That of the Committee of Reference is 8-11, Queen Square, London, W.C.1.

We print in our correspondence columns this week a communication from the Council of the Edinburgh Branch of the British Medical Association strongly opposing the exercise of compulsory powers for the provision of medical attendance on the civil population.

At the annual meeting of the National Medical Union, held on June 1st, Professor William Russell presiding, it was unanimously resolved to advise members of the union not to sign any application for exemption under the new Military Service Act, since to do so might render them liable to be transferred to other localities. The meeting also unanimously confirmed and adopted a resolution of its council approving the principle of compulsory medical service of a purely military nature, but strongly condemning any attempt to extend compulsion in respect of civilian practice.

THE first general meeting since the outbreak of war of the Association of French Doctors was held on April 28th, when it was announced that subscriptions to the special war fund amounted to nearly £38,000, and that of this £6,000 had been expended in grants to practitioners in invaded territory and their families. It was announced that the legacy of Dr. and Madame Dard, of Dijon, to the widow and orphan fund, amounting to £40,000, had been paid over.

British Medical Journal.

SATURDAY, JUNE 8TH, 1918.

A MINISTRY OF HEALTH AND THE FUTURE OF MEDICINE.

A SHORT time ago the Royal College of Physicians of London appointed a committee to report upon the proposals for the establishment of a Ministry of Health. At its meeting on June 3rd it received an interim report from this committee recommending that steps should be taken for the formation with other bodies of a small joint committee on the subject. This recommendation was accepted, and it was further resolved that the joint committee should have power to communicate when necessary with the Government, and to inform it on any part of the subject, reporting its action from time to time to the College. We imagine it to be probable that the Council of the Royal College of Surgeons of England will be disposed to take part in setting up the joint committee, which on matters of administrative detail may find it expedient to enlist the help of experts in public health and general clinical practice. The Scottish Royal Colleges have already set forth their views, but severally and independently, and the joint action proposed in London possesses certain obvious advantages which will be appreciated by the Government and Parliament. A collective expression of opinion must not only be convenient but more likely to carry weight.

It may be assumed that the interest of the Colleges in the proposal for a Ministry of Health is mainly in respect of medical education and the advancement of medicine by observation and research. Sir William Osler in his contribution (p. 653) to the discussion at the Royal Society of Medicine, which has been again adjourned, laid due stress upon this aspect of the matter, instancing the need for the reconstruction of medical schools, the "destruction" of the curriculum, the abolition of unnecessary examinations, and the establishment of up-to-date clinics at the hospitals. He promised that when the younger men returned from the war and took the matter in hand the seniors would stand by and see fair play between them and the authorities, and we imagine that the services of the judicious bottle-holder will be required in the contest that must inevitably take place. The British Medical Association, which must look at the matter from a somewhat different point of view, will, we have no doubt, welcome the proposed joint committee in London as a valuable reinforcement in dealing with the legislature, and as a justification of its contention that the trend of public opinion which found its first expression in the Insurance Act, and is now giving speed to the proposal for a Ministry of Health, is one which nearly concerns every branch of the profession. The pamphlet¹ issued by the British Medical Association a short time ago, giving reasons for the establishment of a Ministry of Health as one of the principal departments of state, together with a scheme of constitution proposed by the Association, has done something to show the hollowness of some of the talk about the complexity of our system of treating and preventing disease and the multiplicity of Government departments interested in health ques-

tions. While pointing out the directions in which the system might be simplified, the pamphlet showed that administration is necessarily complex, because the natural conditions are complex, and that there are many ministries which ought to be able to command the advice of experts, because government is concerned with the proper ordering of human affairs, which are unceasingly affected by the ill or good health of the governed.

In all the recent deluge of talk on public platforms as to the need for a Ministry of Health we can recall little suggesting that the orators had given any thought to the production of the medical hands with which the Ministry of Health must work and without which it would be as helpless as an engine without an engineer. A good deal of lip service to the wonderful advances of medical science was mixed with reproaches against the medical profession that it had not more quickly applied them for the prevention of disease and the promotion of health, but very little anxiety was shown to organize methods for the advancement of medicine and the improvement of medical education. The reports of the two committees to the Prime Minister on the position of natural science² and of modern languages and modern studies³ in the educational system of Great Britain marked a very distinct stage in the growth of opinion, and their recommendations, which appear to command the sympathy of the Board of Education, cannot fail to have a very considerable effect before long on the subjects and the methods of secondary and higher education. The ground is therefore well prepared for any action which the joint committee proposed by the Royal College of Physicians may advise with regard to medical education and medical schools. It is to be noted also that through the establishment of the Advisory Council of Scientific Experts to administer the Imperial Trust for the Encouragement of Scientific and Industrial Research, and in the existence of the Medical Research Committee, we have the elements of a Ministry of Science.

On the other hand, there are the administrative questions with which the pamphlet of the British Medical Association is mainly concerned. On many of these also the value of the opinions of the Royal Colleges will be considerable, especially on all matters concerned with hospitals, and the connexion which should exist between them and the medical schools on the one hand, and general practitioners on the other. On these accounts the step taken by the Royal College of Physicians of London is a matter for congratulation.

THE NERVOUS TEMPERAMENT IN WAR.

MUCH interest has been excited recently in France by Professor Ernest Dupr 's description of a type of psychoneurosis which he would sharply distinguish from neurasthenia on the one hand and hysteria on the other. The interest is due to the belief that the type he has described is a definite clinical entity, and that its recognition will prevent injustice, especially to soldiers. He first published his description in 1910-11, but his papers attracted little attention until Dr. Maurice de Fleury, who had begun to recognize that the type was not uncommon among the cases coming before him during the last two years at the psychiatric clinic of the military hospital of Val de Gr 'ce, brought the matter before the Acad 'mie

³ The Position of Modern Languages (Cd. 9036, price 9d.), BRITISH MEDICAL JOURNAL, May 18th, 1918, p. 567.

¹ *A Ministry of Health*. London: The British Medical Association. Price 3d.

de Médecine a month or two ago.¹ Soon afterwards Dupré himself communicated a very concise paper² to that learned body, of which a fortnight later he was elected a member by a very large majority.

He uses the not very happy term *constitution émotive* for the condition, and describes it as characterized by over-excitability, both sensory and psychic, and imperfect motor inhibition, both reflex and voluntary, so that reactions are abnormal in degree, extent, duration, and in their relation to the stimulus. It is not a traumatic neurosis, inasmuch as it may persist from childhood, but the onset of the symptoms in their fully developed form is usually determined by commotion or emotion intense in degree, or frequently repeated, or by an infection or toxæmia. The psychological signs, which according to Dupré form the groundwork of the condition, are undue impressionability, nervousness, restlessness, anxiety, irritability, and impulsiveness, occurring simultaneously or in alternation. In this soil various combinations of symptoms develop—timidity, scruples, doubts, obsessions, phobias, terrors, and psycho-sexual anomalies. In the more serious cases there may be attacks of melancholia with anxiety, and chronic conditions of obsession passing on to incurable derangement characterized by self-accusations, hypochondria, and negation. All this may be considered a little indefinite, and applicable to many psychoneurotic disorders, but for the diagnosis of the condition he describes Dupré requires the presence of certain physical signs of which he gives a very long list. They include exaggerated reflexes, tendinous, cutaneous, and pupillary; hyperæsthesia with widespread and long-lasting motor reactions (especially mimicry and vocal); loss of motor equilibrium, evidenced by visceral spasm (pharyngeal, oesophageal, gastro-intestinal, vesical, and palpitation of the heart), emotional tremors of the limbs, starting, shivering, chattering of the teeth, stuttering, transitory myoclonus, and tics; functional inhibition, evidenced by loss of power in the limbs, mutism, and relaxation of sphincters; circulatory disturbances, especially tachycardia, constant or paroxysmal, and a variable pulse, and also alternation of peripheral vaso-constriction and vaso-dilatation and dermatography; defective heat control with local variations, objective (local thermometer) and subjective; and glandular disturbance of the sweat, the saliva, of the tears, and of the gastro-intestinal, urinary, genital, and biliary secretions.

Dupré points out that exaggerated emotional response to stimuli is the normal condition in infancy and often persists into childhood, to disappear as inhibition develops with growth and produces nervous equilibrium and stability. In some persons the inhibitory apparatus is imperfectly developed, and is easily thrown out of gear. He does not deny that neurasthenia or hysteria may be grafted on the condition he describes but he insists that it may exist independently of either.

Much credit is no doubt due to Dupré for the observations he made before the war. During the last three or four years the condition described has become familiar to most of those who have had to do with psychoneuroses among cases from the front, and the defect in Dupré's article seems to be that he does not adequately discuss the diagnosis between the condition he describes and neurasthenia, hysteria, some psychopathic states, and simulation. The condition only develops in a predisposed terrain, so that there may be said to be a constitutional disequilibrium of affectivity. It is easy to understand that

such physical manifestations of the condition as shivering and trembling and chattering teeth, embarrassing to the civilian, would be something more to the soldier, for cowardice in the face of the enemy is one of the worst of military offences. M. de Fleury makes the point well by telling a story of Turenne. On a day of battle that illustrious soldier, seized with trembling, no doubt also, it is suggested, with tachycardia and anxiety, exclaimed: "Ah, carcass, you tremble, but if you knew where I am going to take you you would tremble much more." De Fleury illustrated his paper by the history of a young business man who had always been painfully shy; he was mobilized with the rank of lieutenant on August 3rd, 1914, and did his duty well for eighteen months. Then he had to endure a bombardment which lasted nine hours, during which he was buried. This was followed by a phase of well-marked mental confusion, and a few days later he began to suffer from nervous crises, characterized by a feeling of suffocation and general trembling but without loss of consciousness. After five months' rest he was able to return to duty, but in March, 1917, he was again exposed to bombardment (whizz-bangs), and was thereafter seized with intense trembling, sweating, tachycardia, and cardiac anxiety. When examined by de Fleury he exhibited all the symptoms of Dupré's syndrome, and had to be invalided out of the service. He has returned to his business, but is still greatly inconvenienced by the persistence of the respiratory, circulatory, and secretory disturbances, by sudden outbursts of anger, and by neurasthenic depression. The point de Fleury makes is that in such a case as this the individual has been able to repress his emotion and its physical accompaniments until some traumatism breaks down his resistance.

THE BIRTHDAY HONOURS.

THE birthday honours include a considerable number of members of the medical profession. As will be seen from the list printed elsewhere the great majority are awarded in recognition of war services rendered in a naval or military capacity. Among the appointments and promotions within the various orders Surgeon-General H. D. Rolleston, senior physician to St. George's Hospital, who has been actively employed as consulting physician to the Royal Navy since the outbreak of war, has been promoted to be K.C.B. The Companionship of the Bath is conferred upon Deputy Surgeon-General Robert Hill, who has been principal medical officer of the Grand Fleet, and on Major-Generals Sir Anthony Bowlby and Cuthbert Wallace, consulting surgeons with the British armies in France, as well as on Major-General Stanistreet, Deputy Director-General, War Office. Five medical men receive the honour of K.C.M.G.: Major-General Sir Berkeley Moynihan, C.B., a member of the Army Medical Advisory Board; Colonel Sir Ronald Ross, K.C.B., F.R.S., who has been employed on special malaria duty for the army; Surgeon-General M. W. O'Keeffe, C.B., who is D.M.S. of one of the British armies in France; Colonel Sir William Leishman, C.B., F.R.S., who until his recent return to work at the War Office was pathological adviser to the army in France; and Colonel W. H. Horrocks, C.B., a member of the Army Medical Advisory Board and co-editor of the *Journal of the Royal Army Medical Corps*. Among those who receive the Companionship of the Order are Deputy Surgeon-General P. W. Bassett-Smith, R.N., whose work in pathology and bacteriology has been of the greatest value to the navy; Colonel H. M. W. Gray, C.B., consulting surgeon with one of the armies in France; Colonels Armstrong, Elder, and Snell, of the Canadian Army Medical Corps, and Colonel Huxtable, of the Australian Army Medical Corps; Lient.-Colonels Tewsley of the New Zealand, and

¹ *Rev. Scientifique*, 1918, No. 9, p. 257.

² *Bull. de l'Acad. Méd.*, lxxix, p. 286.

Badgerow of the Canadian Army Medical Corps; Major Cluny Macpherson of the Royal Newfoundland Regiment, and Professor H. L. Ferguson of the University of Otago. We also notice the name of Major Maurice Sinclair, R.A.M.C., who has done so much to systematize the treatment of fractures of the femur. The K.C.I.E. is conferred upon Lieut.-Colonel W. J. Buchanan, I.M.S., Inspector-General of Prisons, Bengal; and among those to whom the C.I.E. is awarded is Colonel Patrick Hehir, C.B., who served with so much distinction in Mesopotamia. Sir Alfred Keogh, G.C.B., becomes G.C.V.O., and Lieut.-Colonel Sir Edward Worthington, C.M.G., M.V.O., Assistant Director-General at the War Office, is promoted to be K.C.V.O. The honour of knighthood is conferred upon Colonel A. W. Mayo-Robson, formerly of Leeds, who has been for some years consulting surgeon in the Southern Command at home; upon Mr. Harry Baldwin, dental surgeon to the King and past president of the Odontological Section of the Royal Society of Medicine; and upon Dr. Nilratan Sarkar of Calcutta. Sir Frederick Treves is appointed to the Order of the Companions of Honour, instituted a year ago. To these and to the many others who have received distinctions and promotions we offer congratulations in the name of the medical profession, while the knighthood conferred upon Mr. Peter Squire will be noted with pleasure by the great number of medical practitioners to whom *Squire's Companion to the British Pharmacopoeia* has proved a useful friend. The lists of appointments to the Order of the British Empire will be published in the *London Gazette* on June 8th, with the exception of the appointments to the Order in respect of services in or for the Dominions and Colonies, which it has been arranged to defer until September.

STATEMENT BY THE MINISTRY OF NATIONAL SERVICE.

THE Minister of National Service is issuing to all medical practitioners a statement with regard to their position under the Military Service Acts, 1916-1918. This sets out at considerable length the way in which the present national emergency affects the provision of sufficient medical services, both for the forces and for the civil community; the measures which are held to be requisite for meeting simultaneously both kinds of needs; and the procedure to be adopted in the selection of doctors for services of various kinds. A historical survey is given of the circumstances which have led the Government to place doctors under an exceptional obligation not simultaneously placed on other members of the community as regards military and civil work. The regulations made under the new Military Service Act are next discussed, with a view to explaining why it will no longer be possible for a doctor who bases his claim for exemption on occupational grounds—that is, grounds of national interest—to be granted exemption from military service on the condition merely of continuing in his present practice. The condition of exemption in such a case will be that of rendering professional services in such places and under such conditions as those competent to judge may deem best in the national interest. But, in order that the best interests of the medical profession as well as those of the community may be conserved, the full co-operation of the profession through its central and local organizations formed for the purpose, and also of its individual members, is recognized as essential. The statement then passes from general considerations to an outline of the procedure to be followed—a matter with which we deal at page 647. It is noted that the calling up of medical practitioners will be conducted in such a way as to avoid all unnecessary disturbance to the medical service of the country, and emphasis is laid on the point that doctors should continue their work as before unless and until called up for service. Since no reference

is made in the statement to the proposed "certificate of protection," it is to be assumed that the arrangements for carrying this plan into effect have not yet reached their final form.

THE UTILIZATION OF STUMP MUSCLES

COMMUNICATIONS made by Italian surgeons to the Inter-Allied Conference on the after-care of discharged sailors and sold. rs, which were summarized by Professor Vietor Putti of Bologna in his address to the Royal Society of Medicine, of which a report is published in this issue, are welcome contributions to our knowledge of what may be called the secondary surgery of amputations. For although the ante-bellum work of Vanghetti,¹ and the later work of his imitator Sauerbruch, was known in this country, hardly any practical application of the Italian teaching has been made here, and, as far as we know, nothing has been published here. Sauerbruch recorded a case in Germany in 1915, and returned to the subject twice in 1916,² when he published a monograph in which those operative procedures which he has employed were fully described and illustrated. Since then the Grand Duchy of Baden has placed at his disposal in Singen the means of further testing the value of Vanghetti's methods. So far as we are aware, however, very little evidence is available as to the results obtained, and most German surgeons appear to be cautiously sceptical upon the subject. British surgeons have doubtless been too busy in doing the obviously necessary work of war surgery to devote time to a procedure of which the practical value had not been established, but Professor Putti's demonstration and lecture and his published account of his experience—he has, we believe, operated upon fifty cases—should stimulate them to give the method a thorough trial, the more so as it can be carried out without exposing the patient to much risk of finding himself worse off, in case of failure, than he was before the intervention. It is in cases of loss of both hands that cinematization is best worth trying, for the needs of these unfortunates are the most crying, and any help in such cases is worth having. In one-armed cases the value of prosthetic appliances is much less, since the surviving hand so soon learns to do double duty. In all cases it would seem wise to resort to cinematization as early as possible, before the patient is used to one-handed life, or has become discouraged by long hospital experience. In this connexion it is noteworthy that a recent German writer refers to the difficulty of persuading patients to submit to the operation.

THE PSYCHOLOGY OF THE ALARMIST.

ONE of the sorest afflictions in times of anxiety like the present is the gloomy prophet who goes about crying out that "all is lost." The vaticinations of Cassandra must have dispirited the Trojans even when they shut their ears most obstinately to them. The defenders of Jerusalem must have felt relief when the seer who ran round the walls ingeminating the fall of the doomed city was slain in the act of calling out woe to himself. Such alarmists we have now in plenty among us. They are represented by the eternal type of the "Fat Boy" who takes a mischievous pleasure in making people's flesh creep; by the fussy person who asks debating questions in Parliament; by the pessimist whose mental constitution leads him to look at the black side of things; and by those newspapers whose characteristic note is sensationalism or which find a market in scaremongering. In a paper read before the Paris Academy of Medicine on April 16th, Dr. Ch. Vallon, physician to the great Paris asylum of St. Anne, stated that by an extension of the French press law of July 29th, 1881, promulgated on August 15th, 1914, the utterance of certain statements in such a way as

¹ *La Chir. d. Organi di Movimento*, vol. i, pp. 71, 293, 400, 419; vol. ii, p. 1.

² Sauerbruch, *Med. Klinik*, October 10th, 1915, p. 1125, Berlin. *Zeit. für Orthopädische Chirurgie*, vol. xxxvi, 1916. *Die Willkürliche Bewegbare Künstliche Hand*, Berlin, 1916.

to be heard by a smaller or larger number of persons simultaneously makes the offender liable to certain penalties. He classified the alarmists produced by the war as criminals, victims of vanity, or pessimists. The criminals were amenable to the law in the ordinary way. So were the vain persons, who talked sensationally because they wished it to be supposed that they had relations with highly placed officials; they also might render themselves amenable to the law. The pessimists were very often persons suffering from disease. Many of the vain alarmists were weak-minded or ill-balanced, but others were hypochondriacal or dyspeptic; and it was the duty of the medical expert to make this plain to the court. In such persons responsibility was diminished and they formed a transition group between the weak-minded vain persons and those suffering from definite mental disorder. In a large number of such persons—melancholics and others affected with various psychoses—the wanderings of their mind are governed by the war news. He instanced the case of a man who had been discharged from the army soon after the beginning of the war for syphilis of the nervous system; his native town was subjected to bombardment, which upset him so much that he took refuge in Paris, where he obtained work in a munition factory, and soon began to spread alarmist reports among his fellow-workmen. He was arrested, and upon him were found sheets of paper, covered with notes in pencil, relating to imaginary defeats of the French forces. The man had, in fact, kept a journal of his delirium, and all his supposed facts were inventions. The medical evidence convinced the court that the man required treatment for his disease and not punishment. Vallen's conclusion is that all alarmists should be regarded with suspicion; some of them are conscious evildoers, others persons suffering from disease—very often brain disease—but they ought all to be either punished or brought under control, for if there were many of them in a community they might be a danger by weakening public confidence. Instead of listening to these cowardly voices we should in times of stress adopt the attitude of the Roman Senate which passed a vote of thanks to a defeated general for not having despaired of the Republic.

WASTAGE AMONG WOMEN WORKERS.

THE Medical Research Committee has issued a report,¹ by Captain M. Greenwood, of the welfare and health section of the Ministry of Munitions, on the causes of wastage of labour in munition factories employing women. The report is founded upon a statistical examination of certain factories—a London factory with full records, a country factory, a Midland factory with conditions intermediate between the first two, and factories for heavy work. The inquiry embraced nearly 40,000 employees in eighteen representative factories, but the completeness of the data varied in different instances. In the case of the London factory records existed from 1911 onwards, and the analysis was brought down to the beginning of December, 1916. It was found that the causes assigned by women for leaving work could be classified in three categories—those who left on account of ill health, those who left for some other sufficient reason, and those who left for no reason or an insufficient one. Both in peace and war the rate of loss in the first two or three months of service was heavy. It would appear that of 1,000 girls entering the factory, 132 did not outstay the second month, and that about one hundred of these left for no sufficient reason. A comparison, indeed, suggests that when the losses from all causes are considered the experience was somewhat more favourable in peace than in war. Taking the loss of effectives within the first three months to be not less than 10 per cent. of the original strength—it was probably more—

the question arises as to the causes of a period of employment so short that little useful service can have been rendered. Various causes are suggested as contributing to the result. The first is the fault of the employee herself, such as caprice, unwillingness to submit to discipline, or love of change for its own sake. The second cause suggested is fault in the employer, who does not show judgement in the selection of candidates for employment, the conditions of which are unknown to the applicant but known to the employer. It is suggested also that a third contributory cause may be similar lack of judgement on the part of the officials of the labour bureaux. These officials and factory administrators indulge in mutual recriminations, and it does not seem probable that it will be easy to overcome this difficulty, but its remedy is outside the scope of the report. From a comparison of the effects of munition work in relation to the age of the workers, the conclusion is that the general strain of factory life in itself is not worse borne by elder than by younger women, even in factories engaged upon chemical work which is often associated with specific dangers. But if the factory life is combined with more than a very moderate degree of actual physical work women over 23 come less well through the ordeal. The difference, though not great, is distinct enough to make it a matter of practical importance to attempt to institute a system for recruiting the older women for the physically lighter work and the younger women for the more strenuous labour. This appears to be the most important practical conclusion to be drawn from the report. The early age after which strain becomes too great is noteworthy; it occurs during physical maturity, and its most plausible explanation is that the older women, of whom a larger proportion than of the young women will be married and have young children, have not sufficient reserve of energy to meet the double demand. In an introductory note the Committee bears testimony to the thoroughness with which Captain Greenwood has availed himself of the exceptional opportunities afforded him for the inquiry, and expresses the belief that his numerical data, which are set out in a large number of tables, will long serve as a standard for reference when subsequent work of a similar kind is undertaken in the future.

THE MEDICAL WOMEN'S FEDERATION.

THE first annual meeting of the Medical Women's Federation was held in London, with Dr. Jane Walker, the President, in the chair, and was largely attended by members from all parts of Great Britain. The question of the status of medical women employed in military hospitals under the War Office was discussed. It was felt that these women, through the absence of military rank, were serving under a serious disability involving loss of professional standing. It was unanimously agreed that the Federation should take every means in its power to press for temporary rank for medical women in the military hospitals on the lines of the Territorial R.A.M.C. A draft scheme of maternity and child welfare had been drawn up, but the meeting was in favour of postponing the preparation of the final draft until the question of a Ministry of Health was settled. A statement was made by Dr. Mary Bell, the Federation representative on the Central Medical War Committee, inviting the Federation to nominate three or four representatives to discuss with the Executive Subcommittee of the C.M.W.C. in what way the services of medical women can best be used to take the place of medical men called up under the new Military Service Act. It was unanimously resolved that Regulation 40 D under the Defence of the Realm Act, which makes it an offence for any woman suffering from venereal disease to solicit or to have sexual intercourse with a member of His Majesty's forces, ought to be immediately withdrawn, and a special committee was appointed to consider and report upon the matter in all its bearings.

THE EPIDEMIC IN SPAIN.

THE widespread epidemic of an acute catarrhal affection in Spain, which was stated in our last issue to be most probably influenza and attended by little or no mortality, is now reported to have caused 700 deaths in ten days, but if the number of cases has been as large as reported the case mortality must have been very low. The *Times* of June 3rd quoted Dr. Pittaluga to the effect that the disease attacks the respiratory rather than the abdominal organs; that relapses frequently occur within a few days; and that, although the disease is clearly of the character of influenza, bacteriological examination has not resulted in the discovery of the influenza bacillus, but has revealed an organism described as the parameningococcus. It is well known that the *Bacillus influenzae* is quite commonly absent in cases clinically characteristic of influenza, and that the *Micrococcus catarrhalis*, which has some superficial resemblance to the parameningococcus, is very commonly found. Although, as recent reports of the Medical Research Committee have shown, an epidemic of meningococcus carriers may reach a very high percentage amongst contacts, we are not cognizant of any previous outbreak of cerebro-spinal fever in any degree comparable in extent to the epidemic in Spain. Before coming to any conclusion it is obvious that further bacteriological information must be awaited.

SIR ARTHUR SLOGGETT.

GENERAL SIR ARTHUR SLOGGETT before leaving France was the recipient of many spontaneous proofs of the general recognition by all branches of the army of the success of his administration during three years and three-quarters of strenuous work as Director of Medical Services, British armies in France, and of the high personal regard and esteem in which he is held. Sir Arthur Sloggett, though he has vacated his appointment in accordance with the age and time limits of the army, is still happily endowed with health and energy, and may yet, we hope, be able to render further service to the country.

THE Inter-Allied Food Commission, which, as has been reported, held its first meeting in Paris last November and its second in Rome last March, is meeting this week in London. It is attended by representatives of France, Italy, Belgium, United States of America, and Great Britain. The first business of the commission was to establish physiological principles as to the amount of food necessary for each individual, distinguishing age and sex, and then forming an estimate of the total food requirements of each country. A census of the production of food-stuffs in each country is now being made, and in this way the deficit, which must be met by importation into each country, will be ascertained.

Medical Notes in Parliament.

Territorial Medical Officers.—Commander Bellairs asked Mr. Forster, on June 3rd, whether the War Council had considered the grievance under which the Territorial Force officers of the Royal Army Medical Corps laboured in spite of all their pre-war service in receiving rates of pay and gratuities less than temporary Royal Army Medical Corps officers; and whether the War Council had further considered the favourable report of the Committee of 1917 recommending that the position in regard to pay, allowances, and gratuities of officers in the Royal Army Medical Corps belonging to the Territorial Force and Special Reserve should be equalized with that of temporary officers when they would gain thereby. Mr. Forster, in reply, referred to an answer he gave on February 21st, when he stated that the question was fully considered by the Cabinet Committee on officers' pay, and it was decided not to make the change proposed. These Territorial officers, he added, got the same emoluments as regular officers, and, like them, got the new allowance for children at full rates in the junior ranks, while the officers serving under special contract had half rates only.

Hospital Treatment of American Wounded in England.—Sir Bertram Falle asked Mr. Macpherson, on June 3rd, if he were aware that all the hospitals, including the Royal Hospital, the Fausell Road Hospital (400 beds), the Union Infirmary, and a number of private houses lent to the Voluntary Aid Detachment, Portsmouth, were being taken over by a United States staff, and that the English staff and patients were being sent wherever there was a corner for them; and if he would secure at least the preservation of the Royal Hospital and the Union Infirmary for the English staff and English patients. Mr. Macpherson replied that, owing to the present conditions of fighting in France, some American and British wounded were being brought to this country in the same convoys, and were being treated in British hospitals. It was the desire of the American authorities that their medical and nursing staff now available in this country should undertake some portion of the charge in our hospitals of American and British soldiers. With a view to taking advantage of the generous offer of our ally and freeing British staffs for other hospitals two sections of a general hospital at Portsmouth had been examined, and he hoped that necessary arrangements would be made. British soldiers would not be ejected from the hospital, but as vacancies occurred the majority of patients admitted would probably be American.

Ministry of Health (Scotland).—Mr. Munro informed Mr. Hogge, on May 30th, that until the general proposals for a Ministry of Health had been discussed and adjusted in the War Cabinet he could not make any statement as to the policy of the Government with regard to Scotland.

Travelling Vouchers for Hospital Visits.—Mr. Forster, in a written answer to Mr. Jowett on May 30th, stated that vouchers were issuable at the discretion of medical officers in charge of hospitals which enabled relatives visiting officers and soldiers in hospital in the United Kingdom to travel by rail at single fares for the double journey without the 50 per cent. war increase, provided that the journey was not less than ten miles in the outward direction. Only one visit was allowed in each case, unless the medical officer in charge of the hospital considered in exceptional cases that a second visit was desirable. Two full tickets could be issued for any one visit. Relatives must obtain the vouchers beforehand from the officer in charge of the hospital.

British Doctors in Prisoners' Camps in Turkey.—In a written reply to Mr. Hume Williams (May 30th) Mr. Macpherson has stated that under the Berne agreement of December last one British medical officer and five medical personnel of other ranks might be detained in Turkey per 1,000 British prisoners. The question of increasing the number, if found to be insufficient, was under consideration. It was hoped that the Turkish authorities would make a suitable distribution of this medical staff. The Netherlands Minister at Constantinople would doubtless include this among the many other points in which our interests were involved under the agreement. In reply to a further question, Mr. J. F. Hope wrote that the Turkish Government had not yet given notice of the date upon which the 1,000 British invalid prisoners to be exchanged would be ready for embarkation, and he feared that in the most favourable circumstances it must be a considerable time before the first exchange took place. No inspection of internment camps in Turkey under the Berne agreement had yet taken place, but a representative of the Netherlands Government had left the Hague for the purpose on May 24th, and it was hoped that the inspections would shortly begin.

THE FUTURE OF THE MEDICAL PROFESSION UNDER A NATIONAL HEALTH MINISTRY.

THE first part of this discussion at the Royal Society of Medicine was reported in the *BRITISH MEDICAL JOURNAL* of April 20th (p. 456). The discussion was resumed on May 29th.

SIR WILLIAM OSLER said that upon two points there was more or less agreement: First, the urgent need of co-ordination in the various departments which now dealt with public health; secondly, that the nationalization of medicine had of late progressively advanced, recent legislation having brought the state to the door of the general practitioner, and, willy-nilly, he had become in some measure a civil servant. Much of this legislation had lacked effectiveness owing to a timorous regard for the fetish of local authority. The profession had too often suffered the pace to be set by organized ignorance, but there was hope in the Local Government Board, where the spirit of Sir John Simon still lived; the Board should form the nucleus of the new department. There were three contentious points: (1) Was a scheme possible in which the general practitioner should be a paid official of the state and yet independent—a civil servant and yet a free agent, the executive officer of a city or county council and yet alive to the needs of science? He wanted to conserve the competition which had had such an important place in the life of the profession for at least two thousand five hundred years, as

illustrated by the bidding of the free Greek towns for Democedes. He was less worried about the choice of doctor than about the choice of practice, and the individual development of the progressive, ambitious man who loved his profession, hated politics, and was too honest to pull wires. (2) What was to be the relation of the state to research? The prejudice in some quarters against state aid was an academic obsession, peculiarly insular and Anglican. Apart from Lister's work on infections, practically all the first-hand discoveries made in this country had been made by men in official harness, such as Griffith Evans, Manson, Ross, Bruce, and Leishman. The debt of the profession was a hundredfold greater to the Local Government Board for its researches in preventive medicine than to all the universities combined. (3) What was the position of the hospital in the scheme? The hospital should form the unit or the centre around which the general practitioners should coalesce. The hospitals were preparing for the change, and within a few years there should be a thoroughly practical working combination of the voluntary agencies with the state. To come into a national scheme there would have to be some radical alterations in the arrangement of the staff. Speaking of medicine only—for nowadays they "could grow surgeons anywhere," while the modern physician was a man of much broader gauge and harder to cultivate—he recognized that in any new scheme there must be a reduction in the number of attending physicians, and he drew an amusing picture of the "growing" of a good consultant according to Major Dill's scheme brought forward at the previous discussion. In conclusion, Sir William Osler said that a strong Ministry of Health, backed by a united profession, could initiate important reforms which seemed at present hopeless. The reconstruction of medical schools; the reform, or rather the destruction, of the curriculum; the establishment in the hospitals of up-to-date clinics, the abolition of unnecessary examinations—some of these reforms at least a strong central organization could force through against the blind opposition of vested interests. These were *post-bellum* problems for the young men, and it would be a pleasure for the seniors to stand by and see fair play between them and the public as represented by the authorities.

Mr. E. B. TURNER said that eighteen central and nine local departments were concerned with public health, and every practitioner who had thought on the subject would agree that a Minister of Health should be appointed to co-ordinate the overlapping interests. He should have Cabinet rank, and be assisted by an advisory board representing the skilled knowledge of the profession. Such a Ministry should have three different spheres of action: (1) Preventive medicine; (2) medicine having to do with the clinical treatment of individuals; (3) research, upon the success of which the success of the other two would depend. The Ministry should take over every department which had to do with health, including the medical department of the Poor Law, and there, of course, arose difficulties, as instanced in the Education Bill, which secured a large field for inspection and treatment to the medical department of the Board of Education. Government departments in the past had put clinical work in a position of disadvantage to preventive; under a Ministry of Health the officers responsible for the preventive and for the clinical side should have equal status, and those who did the administrative work should have some years of clinical training. He hoped that the voluntary hospitals would remain; it would be an exceedingly good thing to continue and extend the principle of the cottage hospital. The general practitioner also should be given as wide opportunity and working power as possible. Abundant use must be made of the general practitioner if the public health was to be served and the utility and independence of the profession maintained.

Dr. J. C. McVAIL said that it behoved those who were anxious that a Ministry of Health should at last be established to avoid discussion which might hinder rather than help. The primary question, he thought, was the extent and character of the services which the Ministry would wish from the medical profession; when that was settled the terms and conditions would fall to be considered in relation to the decision. He disagreed with Sir William Osler in what he had said about the bearing of competition upon the character of the service. Those who had had a fairly long experience in public health matters were not

afraid of doctors becoming officials. The present public health service had not settled down into a routine because it was official. The country was now alive as never before to the importance of the physical welfare of the individual in the interests of the nation, and also to the fact that the medical profession alone could supervise the work. The share the medical profession could take in the work of reconstruction was to establish a department of medical service which should be devoted not to the treatment of disease but to the maintenance of health.

Dr. WILLIAM GORDON said that it was essential to preserve "soulful" contact between patient and doctor, and this could be done by making the general practitioner the backbone of the whole business. He believed with Sir William Osler that if competition were abolished the work of the practitioner would suffer. The Insurance Commissioners had met such a situation with a compromise, which, he thought, with some changes, might be extended over a wider field. A system of part-time service might be inaugurated in which a man should be in part a Government servant and in part in competition with his fellow practitioners. The medical profession must itself have an adequate voice in the new Ministry; it was of no use to have an advisory committee which was merely ornamental. He thought also that the Minister himself should be a medical man.

Dr. HAYDN BROWN said that a Ministry of Health should alone be considered now; when that was formed the question of a State Medical Service would come up in its turn to be fought out by the Ministry aided by the medical profession. The British Medical Association made the claim that many years ago it had put forward the suggestion which was now becoming practical politics. But what had the medical profession done since to further it? It was the laity, notably Lord Rhondda and Mr. Waldorf Astor, who had stimulated the present movement. He suggested the formation of a Section of Medical Economics in the Royal Society of Medicine.

Dr. SMITH WHITAKER expressed the opinion that specialist treatment covered two different things—the kind of service which could only be rendered satisfactorily by a man who had concentrated his study on the subject, and the kind which only necessitated access to special apparatus and accessories, such, for instance, as the diagnosis and treatment of venereal diseases; under a Ministry of Health the general practitioner might have wider opportunities in this second respect.

Sir WATSON CHEYNE, in a few words, said that to get a Ministry of Health was by no means easy, for each Government department was developing its own system of medical supervision, and would be loth to part with it. There was not enough pressure of public opinion to bring matters to a focus. The public needed to be educated.

Dr. G. E. HASLIP pointed out that it was the profession itself which first asked for the interference of the state with medicine—namely, with regard to contagious diseases—and the more disease was studied the more widely the fact of contagiousness was recognized, as, for example, in phthisis. A system of part-time work at clinics and of proper co-ordination with hospitals and specialists would kill any idea of a whole-time state medical service.

On the motion of Sir BERTRAND DAWSON the discussion was again adjourned.

THE distinction of Grand Officer of the Order of the Crown of Italy has been conferred on Count Gian Giacomo della Somaglia in recognition of his "magnificent work" as President of the Italian Red Cross.

PROFESSOR R. PFEIFFER and Dr. G. BESSAU, in a paper (*Deut. med. Woch.*, October 11th, 1917) on the bacteriology of gas gangrene, insist on the importance of distinguishing between Fraenkel-phlegmon and malignant oedema; for the first is a relatively benign, the latter a very virulent infection. The first requires comparatively conservative treatment, the latter immediate amputation allowing a wide margin of healthy tissue. And even so, the patient seldom recovers. They find that both the non-putrefactive bacilli, Fraenkel's and the bacillus of malignant oedema, may cause gas phlegmon. The putrefactive germs play only a secondary part when present along with non-putrefactive germs, and they think it doubtful whether the putrefactive germs by themselves can produce a progressive gas phlegmon. The writers are pessimistic about the prospects of successful serum treatment.

THE WAR.

THE BIRTHDAY HONOURS.

THE following medical names appear in the list of birthday honours published on June 3rd. The military distinctions and promotions have been awarded for valuable services rendered in France and Flanders, Italy, Egypt, Salonica, and the Indian Frontier, or for services otherwise rendered in connexion with the war. All the officers belong to the A.M.S. or R.A.M.C. unless otherwise indicated:

Companion of Honour.

Sir Frederick Treves, Bt., G.C.V.O., C.B.

K.C.B. (Civil).

Temporary Surgeon-General Humphry Davy Rolleston, C.B., R.N.

C.B. (Military).

Surgeon-General Patrick B. Handyside, R.N.
Deputy Surgeon-General Robert Hill, C.V.O., R.N.
Temporary Major-Generals: Sir Anthony A. Bowlby, K.C.M.G., K.C.V.O., and Cuthbert S. Wallace, C.M.G.
Colonel (temporary Major-General) George B. Stanistreet, C.M.G.

Colonels: Stuart Macdonald, C.M.G., Edgar M. Pilcher, D.S.O., Alexander Primrose, C.A.M.C., Gerald T. Rawnsley, C.M.G., Arthur E. Ross, C.M.G., C.A.M.C., G. StClair Thom, C.M.G.

Lieut.-Colonel and Brevet-Colonel (temporary Colonel) Thomas W. Gibbard, K.H.S.

Lieut.-Colonel and Brevet-Colonel Allan J. Macnab, I.M.S.

Lieut.-Colonel John Blackburn Smith, I.M.S.

Temporary Lieut.-Colonel James W. Barrett, C.M.G.

K.C.M.G.

Temporary Major-General Sir Berkeley G. Moynihan, C.B.
Surgeon-General Menus W. O'Keeffe, C.B.
Colonels: William H. Horrocks, C.B. (ret. pay), Sir William B. Leishman, C.B., F.R.S., K.H.P.
Temporary Colonel Sir Ronald Ross, K.C.B., F.R.S. (ret. pay), I.M.S.).

C.M.G.

Fleet Surgeon (acting Deputy Surgeon-General) Percy W. Bassett-Smith, R.N., C.B.

Fleet Surgeons: Frederick J. A. Dalton, R.N., Edward Sutton, R.N., David Walker Hewitt, R.N., and William W. Keir, R.N.

Colonels: George E. Armstrong, C.A.M.C., Robert W. Clements, D.S.O., John M. Elder, C.A.M.C., Wilfred E. Hudleston, D.S.O., Robert B. Huxtable, D.S.O., V.D., A.A.M.C., Daniel O'Sullivan, and Arthur E. Snell, D.S.O., C.A.M.C.

Temporary Colonels: Owen W. Richards, D.S.O., and Arthur S. Woodward.

Lieut.-Colonels (temporary Colonels): Edmund M. Morphew, D.S.O., Harold Collinson, D.S.O., James S. Gallie, D.S.O., John A. Hartigan, D.S.O., Albert G. Thompson, D.S.O.

Lieut.-Colonels: William R. Blackwell, Thomas A. Granger, I.M.S., Albert E. Hamerton, D.S.O., Francis S. Irvine, D.S.O., Cyril H. Tewsley, N.Z.M.C.

Honorary Lieut.-Colonel George W. Badgerow, C.A.M.C.

Major and Brevet Lieut.-Colonel Eugene Ryan, D.S.O.

Major (and temporary Colonel) Henry McI. W. Gray, C.B.

Majors (temporary Lieut.-Colonels): William L. Steele and Edmund T. Potts, D.S.O.

Major (acting Lieut.-Colonel) George H. L. Hammerton, D.S.O.

Majors: Cluny Macpherson, M.D. (Royal Newfoundland Regiment), and Maurice Sinclair.

Temporary and honorary Major Charles G. Jarvis.

Captain (temporary honorary Lieut.-Colonel) Donald J. Armour.

Henry Lindo Ferguson, M.D., Professor of Ophthalmology, University of Otago, New Zealand.

K.C.I.E.

Lieut.-Colonel Walter James Buchanan, C.I.E., I.M.S., Inspector-General of Prisons, Bengal.

C.I.E.

Colonel Patrick Hehr, C.B., C.M.G., I.M.S.
Lieut.-Colonels Ernest Alan R. Newman, I.M.S., and Herbert A. Smith, I.M.S.

Major and Brevet Lieut.-Colonel Frederick A. F. Barnardo, I.M.S.

Major Davis Heron, I.M.S.

John Robertson Henderson, M.B., F.L.S.

G.C.V.O.

Lieut.-General Sir Alfred Keogh, G.C.B., C.H.

K.C.V.O.

Sir Alan Reeve Manby, M.V.O.
Lieut.-Colonel Sir Edward Scott Worthington, C.M.G., M.V.O.

M.V.O.

Charles Percival White, M.B.

Knighthood.

A. W. Mayo-Robson, C.B., C.V.O., F.R.C.S.
Harry Baldwin, M.R.C.S., Dental Surgeon to the King.
Nilratna Sarkar, M.D., Calcutta.

Bar to D.S.O.

*Captain (temporary Lieut.-Colonel) Arthur T. Pitts, D.S.O.

D.S.O.

Lieut.-Colonels (temporary Colonels): Frederick A. Maguire, A.A.M.C., Arthur E. Shepherd, A.A.M.C.

Lieut.-Colonels: George J. Boyce, C.A.M.C., Edward T. Brennan, M.C., A.A.M.C., William C. Croly, Arthur L. Dawson, A.A.M.C., Anson S. Donaldson, C.A.M.C., William E. Foggie, Archibald L. C. Gilday, C.A.M.C., John N. Gunn, C.A.M.C., Joseph Hayes, C.A.M.C., Daniel F. Kappel, C.A.M.C., William E. Kay, A.A.M.C., Montagu M. Lowsley, John Powell, Balcombe Quick, A.A.M.C., Hugh W. Thomson, and John R. Whait.

Major (temporary Colonel) Creighton H. Lindsay, C.M.G.

Majors (temporary Lieut.-Colonels) Richard C. Hallowez, Ernest C. Hodgson, I.M.S.

Majors (acting Lieut.-Colonels): Frederick J. Garland, John W. Leitch, Rowland P. Lewis.

Majors: Thomas A. Barron, Francis L. Bignell, A.A.M.C., Arthur R. Clayton, A.A.M.C., Albert T. Dunnlop, A.A.M.C., Thomas C. C. Evans, A.A.M.C., George H. R. Gibson, C.A.M.C., Charles E. Hercus, N.Z.M.C., Theodore A. Lomer, C.A.M.C., Donald S. Mackenzie, A.A.M.C., Ernest A. C. Matthews, I.M.S., Major Walter J. Stack, A.A.M.C., Alan C. Turner, Wilfred Vickers, A.A.M.C., Douglas P. Watson, and Ralph K. White.

Surgeon-Major Arthur W. Shea (Notts and Derby Regiment).
Temporary Major Harold W. Wiltshire.

Captains and Brevet Majors (acting Lieut.-Colonels) Claude H. S. Frankau and Benjamin Johnson.

Captains (temporary Lieut.-Colonels) Francis W. M. Cunningham and Hector G. G. Mackenzie.

Captains (acting Lieut.-Colonels): William Blackwood, Herbert W. Carson, Colin Clarke, Robert Hemphill, Thomas B. Layton, Arthur N. R. McNeill, Sinclair Miller, M.C., Ernest W. Wade, Alfred J. Williamson.

Captain (temporary Major, acting Lieut.-Colonel) Thomas A. Green.

Captains: Ernest M. Cowell, Ambrose L. Lockwood, M.C., Mervyn J. Holmes, A.A.M.C., Wilfred J. Pearson, M.C., O. Teichmann, M.C.

Temporary Captains (acting Lieutenant-Colonels): Ralph E. Drake-Brockman and Albert Jones, M.C.

Temporary Captains: James A. Conway, M.C., Samuel S. Greaves, M.C., and Wilfred J. Pearson, M.C.

Temporary honorary Captain Humphrey Nockolds.

Bar to the Military Cross.

Captain (acting Major) Hugh H. Robinson, M.C.

Captains: *Thomas S. Elliot, M.C., Arthur E. Ironside, M.C., *Hamilton S. Moore, M.C., and *John Rowe, M.C.

*Temporary Captain George W. B. James, M.C.

Military Cross.

Captain (acting Major) William T. Ewing, C.A.M.C.

Captains: Robert P. Anderson, William D. Anderton (S.R.), Richard P. Ballard (S.R.), Roy D. Bartram, A.A.M.C., Philip B. Benham, N.Z.M.C., Douglas W. Berry, Alexander C. Bryson, Frederick C. Chandler, Eugene H. Coyne, David Dempster (S.R.), James Derham-Reid, George S. Elliston, Charles N. Gover (S.R.), Nicholas H. H. Haskins, Sidney M. Hattersley, Humphrey F. Humphreys, David W. John (S.R.), Griffiths L. Jones (S.R.), Ivan B. Jose, A.A.M.C., Gerald P. Kidd (S.R.), William A. Lethem (S.R.), Donald C. Macdonald (S.R.), William G. Mackenzie, William F. McLean (S.R.), Henry P. Malcolm, Norman R. Mathews, A.A.M.C., Francis R. H. Mollan (S.R.), Cyril E. Petley, George L. K. Pringle, Albert Ramsbottom, Douglas G. Rice-Oxley, Frank H. Robbins, Cedric M. Samson, A.A.M.C., Clement P. Sells, Frank Scroggie, John A. Shauasy, A.A.M.C., John J. McI. Shaw, Robert G. Shaw, Edward S. Simpson, George H. Stevenson (S.R.), Ludwig S. B. Tasker, Francis G. Thatcher, William McN. Walker (S.R.), and Valentine H. Wardle.

Temporary Captains: Wilfred H. Alderton, Francis J. Allen, Robert H. Alexander, Lawrence W. Bain, Geoffrey T. Baker, Stanley Batchelor, William D. Bathgate, William Brownlie, Charles W. G. Bryan, Bloomfield G. H. Connolly, Henry H. Davis, John W. Dew, Leslie W. Evans, Keith D. Falconer, Richard D. Fitzgerald, Ilope M. Gillespie, William E. Hallinan, Randal M. Handfield-Jones, Claude C. Harrison, J. Berry Haycraft, Godfrey J. D. Hindley, Austin H. Hnycke, Joseph G. Johnston, David A. D. Kennedy, Francis J. Lidderdale, Eric A. Lumley, William J. Macdonald, John B. McFarland, Donald MacLutye, Unsack O'Malley, Herbert M. Pentreath, Michael P. Power, Ralph S. Renton, John W. Riddoch, Robert S. Ross, William J. Rutherford, John H. Thornley, James A. Tobin, John Watson, Alexander U. Webster.

Lieutenant (temporary Captain) Desmond W. Beamish.

Quartermaster and honorary Captain Charles F. Fraser.

* The announcements of awards of the D.S.O. and Military Cross in these cases have not yet been published in the *London Gazette*, but will appear in due course.

Quartermaster and honorary Lieutenant George Sellex.
Temporary Quartermaster and honorary Lieutenant George S. Annett.

To be Brevet Colonel.

Lieut.-Colonels (temporary Colonels): W. H. S. Nickerson, V.C., C.M.G., and G. J. A. Ormsby, D.S.O.
Surgeon Lieut.-Colonel E. N. Sheldrake (ret. pay, late Grenadier Guards).
Lieut.-Colonels: F. J. Brakenridge, C.M.G., A. L. A. Webb, C.M.G., and Sir E. S. Worthington, C.M.G., M.V.O.
Temporary Lieut.-Colonel W. L'E. Eames, C.B. (Lieut.-Colonel A.A.M.C.).

To be Brevet Lieut.-Colonel.

Majors (temporary Lieut.-Colonels): E. B. Bird, D.S.O., and O. W. Holden, D.S.O.
Majors (acting Lieut.-Colonels): C. G. Browne, D.S.O., P. Davidson, C.M.G., D.S.O., C. H. Turner, D.S.O.
Majors: H. V. Bagshawe, D.S.O., F. G. Faichnie (ret. pay R. of O.), and C. A. Gill, I.M.S.
Captains and Brevet Majors: H. M. Rigby, K.C.V.O. (temporary Lieut.-Colonel, R.A.M.C.), Sir H. J. Stiles (temporary Lieut.-Colonel, R.A.M.C.).

To be Brevet Major.

Captain (acting Major) A. G. R. Foulerton.
Captains: H. H. Blake, L. G. Bourdillon, D.S.O., M.C., C. C. Frye, J. Gilmour, M.C., and W. J. F. Mayne.
Temporary Captain A. E. Boycott.

To be Honorary Lieut.-Colonel.

Quartermasters and honorary Majors: H. Copping (ret. pay) and A. Wilson (ret. pay).

To be Honorary Major.

Quartermaster and honorary Captain J. W. Osborne.

I.S.O.

William J. Henderson Sinclair, M.B., Medical Officer Barlinnie Prison.
Senior Assistant Surgeon and honorary Major Michael Courtney, I.S.M.D., Superintendent, Central Jail, Montgomery, Punjab.

MENTIONED IN DISPATCHES.

The following officers of the medical services are included in General Sir Herbert Plumer's dispatch dated April 18th, 1918, containing a list of officers and others whose distinguished and gallant services and devotion to duty he considers worthy of special mention.

ARMY MEDICAL SERVICE.

Staff.

Major-General F. R. Newland, C.B., C.M.G.
Colonels: R. J. Blackham, C.M.G., C.I.E., D.S.O., S. L. Cummins, C.M.G., J. V. Forrest, C.M.G., L. N. Lloyd, C.M.G., D.S.O., T. du B. Whaite, C.M.G.
Lieut.-Colonel (temporary Colonel) R. Pickard, C.M.G.
Lieut. Colonel C. H. Furnivall.
Captain T. D. Inch, M.C.
Temporary Captain W. J. Pearson, M.C.

Royal Army Medical Corps.

Lieut.-Colonels W. C. Croly, J. W. West.
Captain (temporary Lieut.-Colonel) T. H. Scott, M.C.
Captain (acting Lieut.-Colonel) A. Irvine-Portescue.
Captains: D. G. Duff (S.R.), H. W. Malthy (S.R.), T. S. Nelson (S.R.).
Temporary Captains: W. E. Bullock, P. J. Chissell, S. J. Drake, M.C., J. L. Davies, J. S. Doyle, W. Duffy, D. G. Gardiner, T. L. Llewellyn, T. Stordy, T. Thompson, H. Upcott, R. R. Watts.
Lieutenant (temporary Captain) T. J. Kelly, M.C.
Temporary Lieutenant T. B. Johnston.
Temporary Quartermasters and honorary Lieutenants: E. G. I. Brice, C. Elliot, T. H. Griggs.

Royal Army Medical Corps (T.F.).

Major (acting Lieut.-Colonel) G. H. L. Hammerton, D.S.O., M.C.
Captain (acting Lieut.-Colonel) T. A. Green, D.S.O.
Captain (acting Major) W. Bowater, M.C.
Captains: L. Ball, G. C. Soutter, B. M. Young.
Quartermaster and honorary Captain S. O. Wright.

Indian Medical Service.

Lieut.-Colonel J. C. Robertson, C.M.G., C.I.E.

The King has awarded the Military Medal to the following five members of the nursing profession for distinguished services during a recent hostile bombing raid on a casualty clearing station: Sister-in-charge Kate Maxey, T.F.N.S., Sister Dorothy P. Foster, R.R.C., T.F.N.S., Acting Sisters Mary A. Brown, P.A.L.M.N.S.(R.), Marie D. Lutwick, Q.A.I.M.N.S.(R.) (Canada), and Miss Lillian A. Forse, V.A.D.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Died on Service.

STAFF SURGEON C. R. M. BAKER, R.N.

Staff Surgeon Cecil Robert Morshead Baker, R.N. died suddenly at H.M. training establishment, Shotley, on May 26th, aged 37. He was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1906, entered the navy as surgeon on May 14th, 1907, and became staff surgeon in 1915.

ARMY.

Killed in Action.

MAJOR E. J. ELLIOT, R.A.M.C.

Major Edward John Elliot, R.A.M.C., was killed on May 23rd, aged 37. He came of an old Border family, and was the sixth owner in direct succession of the estate of Binks, Roxburgh County. He was born on May 5th, 1881, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1904, afterwards acting as house-surgeon of the Radcliffe Infirmary, Oxford. He entered the R.A.M.C. as lieutenant on July 30th, 1906, gained the Parkes Memorial medal in hygiene while at the R.A.M.C. College, became captain on January 30th, 1910, and had recently been promoted to major. He went to France in August, 1914, and was mentioned in dispatches in January, 1916.

Captain D. E. Howes, Canadian A.M.C.

Died of Wounds.

CAPTAIN I. C. MACLEAN, D.S.O., M.C., R.A.M.C.

Captain Ivan Clarkson Maclean, D.S.O., M.C., R.A.M.C., died of wounds as a prisoner in a German hospital on April 4th, having previously been reported as missing on March 24th. He was the son of the late Major-General H. J. Maclean, Rifle Brigade, and was educated at Haileybury and at St. Thomas's Hospital. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1905, and graduated M.B. and B.S.Lond. in the same year, and M.D. in 1909. He subsequently filled the posts of assistant in the x-ray and in the children's surgical department at St. Thomas's, of house-physician to the Brompton Consumption Hospital, and of anaesthetist to the Royal Ear Hospital, St. John. He then went into practice at Knightsbridge, holding the appointments of anaesthetist to the Golden Square Hospital, and of honorary medical officer to the Actors' Association. He took a temporary commission as lieutenant in the R.A.M.C. on August 19th, 1914, and was promoted to captain after a year's service. Most of his service was spent in France with his father's old corps, the Rifle Brigade. He received the Military Cross on June 23rd, 1915, for Neuve Chapelle; a bar for the battle of the Somme on December 21st, 1916; and the D.S.O. on September 26th, 1917, for the third battle of Ypres, where he was severely wounded; he went to the front again last January. His younger brother, Lieutenant A. C. Maclean, R.E., was killed on April 9th.

LIEUTENANT W. E. BROWN, R.A.M.C.

Lieutenant W. E. Brown, R.A.M.C., was reported as having died of wounds, in the casualty list published on May 29th. He was attached to the Duke of Wellington's, the West Riding Regiment.

Died on Service.

LIEUT.-COLONEL F. W. THOMSON, I.M.S.

Lieut.-Colonel Francis Wyville Thomson, Bengal Medical Service (retired), died suddenly at Bouside, Linlithgow, on May 27th, aged 58. He was born on February 7th, 1860, the only son of the late Sir Charles Wyville Thomson, of *Challenger* fame, professor of natural history in Edinburgh University, and was educated at that university, where he graduated M.A. in 1880, and M.B. and C.M. in 1886, also taking the D.P.H. of the R.C.S.Ed. in 1892, and the Liverpool diploma in tropical medicine in 1905. Entering the I.M.S. as surgeon on September 30th, 1886, he became major on September 30th, 1898, and lieutenant-colonel on September 30th, 1906, retiring on March 14th, 1908. He served on the North-

West frontier of India in the Waziristan campaigns of 1894-95 and of 1901-02, receiving a medal and clasp for each, and in the third China war of 1900, when he took part in the relief of Peking (medal with clasp). During the present war he had served as senior medical officer of the T. & Y. defences. Most of his service in India was spent in military employment.

MAJOR A. WESTLAKE, R.A.M.C.(T.F.)

Major Algernon Westlake, R.A.M.C.(T.F.), died at Grimsby on May 25th, aged 59. He was educated at the universities of Edinburgh, where he graduated M.B. and C.M. in 1884, and Manchester, after which he filled the posts successively of house-surgeon of Hertford General Infirmary, resident medical officer of the District Hospital, Great Grimsby, and medical superintendent of the Grimsby Corporation Small-pox Hospital. He then went into practice at Grimsby, also holding the appointments of honorary surgeon to the Grimsby and District Hospital and to the Grimsby Church Schools, honorary physician to the Grimsby Nursing Institute, medical officer to the borough police and to the Grimsby Workhouse, and public vaccinator to No. 2 District of Grimsby Union. He had been Vice-President of the East Yorks and North Lincoln Branch of the British Medical Association. He held a commission, dated October 14th, 1908, as Major R.A.M.C.(T.F.) in the 4th Northern (Lincoln) General Hospital.

CAPTAIN L. H. Y. STEPHEN, R.A.M.C.

Captain Lionel Henry Yorke Stephen, formerly of Lutterworth, Cambridgeshire, and Folkestone, Kent, died of acute tuberculosis at Bournemouth on May 22nd, 1918. The sixth son of the late James Stephen, Judge of No. 17 County Court Circuit and writer of *Stephen's Commentaries*, he entered Guy's at a later age than the average student, and became M.R.C.S. L.R.C.P. in 1897. After filling resident appointments at two institutions, he went as a civil surgeon to South Africa on the outbreak of the Boer war and served there until invalided in 1901 after a severe attack of typhoid fever. On the outbreak of the present war he was, in view of his previous experience, reaccepted for service despite his being much over the age limit of the time, and went out with the first expeditionary force. Eventually pleuritic effusion caused him to be relegated to home service, and the remainder of his life until three months ago was spent as registrar at the Military Hospital, Dover. Of notably open-handed disposition and popular with all sorts and conditions of men, he died at the age of 49 and is survived by a wife and two children.

Wounded.

Lieut.-Colonel K. D. Murchison, D.S.O., R.A.M.C. (S.R.).
Major G. D'R. Carr, M.C., R.A.M.C. (temporary).
Major A. R. Clayton, Australian A.M.C.
Major E. B. Hogan, Canadian A.M.C.
Major H. E. Macdermot, Canadian A.M.C.
Major O. R. Mcrillees, Australian A.M.C.
Captain R. B. Anderson, Canadian A.M.C.
Captain J. H. Bensted, R.A.M.C. (temporary).
Captain J. N. Cruckshank, R.A.M.C. (temporary).
Captain C. A. Davies, Canadian A.M.C.
Captain M. Ffoulkes, R.A.M.C. (temporary).
Captain E. M. Gordon-Glassford, M.C., Australian A.M.C.
Captain W. B. Jack, R.A.M.C. (temporary).
Captain G. B. McGregor, M.C., R.A.M.C. (temporary).
Captain W. F. McIsaac, Canadian A.M.C.
Captain H. K. Mitchell, Canadian A.M.C.
Captain A. J. Neilan, R.A.M.C. (temporary).
Captain H. C. Pearson, Canadian A.M.C.
Captain R. K. Rae, Australian A.M.C.
Captain J. H. Walmsley, Canadian A.M.C.
Captain and Quartermaster R. J. Fleming, R.A.M.C.
Captain J. H. Duff, Canadian Army Dental Corps.

Wounded and Missing.

Captain P. M. McLachlan, M.C., R.A.M.C. (temporary).

Prisoners of War.

Captain F. Dallimore, M.C., R.A.M.C. (temporary).
Captain F. C. Nichols, R.A.M.C. (T.F.).
Captain D. A. Wilson, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Deane, Gordon Alexander, Captain Royal Irish Fusiliers, eldest son of Dr. Charles C. Deane, of Longhall, co. Armagh, died of wounds on April 11th, aged 23. He got his commission on March 17th, 1915, and went to the front in February, 1917.

Fry, Edwin Harries Sargood, Major R.G.A., son of Dr. E. S. Fry, Secretary of the Edinburgh Medical Missionary Society, died of wounds in a casualty clearing station on May 15th, aged 23. He was educated at Watson's College, Edinburgh, and became an engineer. When the war began he was a member of the Forth Defence Company of the Royal Engineers (T.F.). He got a commission in November, 1915, went to the front in January, 1917, and had previously been wounded. Two of his brothers are serving, one in the I.M.S. and one in the Royal Air Force.

James, C. K., Lieut.-Colonel Border Regiment, attached West Yorkshire Regiment, only surviving son of Dr. C. A. James, of Upper Clapton, killed on May 19th, aged 26. He was educated at Cheltenham College, and at Caius College, Cambridge, where he held a scholarship and graduated as B.A. In February, 1914, he went to Shanghai. When war began he returned at once, and got a commission in the Border Regiment. He became lieutenant in March, 1915, went to Gallipoli, and was wounded at Anafarta. He became captain in August, 1915, went to France in July, 1916, and received the D.S.O. after the battle of the Somme. In January, 1917, he was promoted to major (temporary); in March, 1917, temporary lieutenant-colonel, commanding a battalion of the West Yorks; he received a bar to the D.S.O. for Cambrai, had been six times mentioned in dispatches, and last March commanded a brigade.

We are informed that Captain M. T. Ascough, M.C., R.A.M.C. (T.F.), who was reported missing in our issue of April 13th, is a prisoner of war and unwounded.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

Correspondence.

TUBERCULOSIS OFFICERS AND THEIR WORK.

SIR,—In the BRITISH MEDICAL JOURNAL of May 25th, in an article under this heading, some suggestions are made to which a large number of practitioners will take grave exception. One wonders whether it be quite politic to draw comparisons between the state medical officer and the private practitioner, and why the former is considered more competent to recognize tuberculosis in its earlier stages than the latter; but there are other and more important considerations to which I wish to draw attention.

The explanation put forward for the delay in notification—namely, that it is due to the mistaken idea that a positive diagnosis is not justified until bacilli appear in the sputum—may often be given, but I suggest that a more honest explanation is a desire of the practitioner to refrain from the objectionable task of notification so long as he can cling to the hope that the disease is curable. This explanation may be surprising, but analyse the reasons a little further and it will surprise few.

"The gradual weeding out of the dangerous elements" is no new method of attempting to eradicate disease from a community. It is not a twentieth century innovation, and is not even confined to the human species. There are three quotations which might be well placed together. The first is from the Levitical law on leprosy, "All the days wherein the plague shall be in him he shall be defiled; he is unclean; he shall live alone; without the camp shall his habitation be." The second is from your leading article: "But in the case of tuberculosis, the interests of the individual must give place to those of the community in which he lives, and his medical adviser, whether he be acting in a private or in a panel capacity, should refuse to aid in the suppression of the truth." The third is from the Hippocratic oath: "Whether in connexion with my professional practice or not in connexion with it I shall see or hear in the life of men which should not be spoken of abroad I will not divulge, as reckoning that all such should be kept secret. While I continue to keep this oath unviolated, may it be granted to me to enjoy life and the practice of the art respected by all men in all time."

Might I suggest that the attitude of the community towards disease through all ages, which finds expression in the first two quotations, made the Hippocratic oath a necessity for the practice of the art? Would Hippocrates have consented to the notification of leprosy? Will it prove ultimately in the interests of the community to lightly cast aside the experience of many great medical thinkers of the past, and abolish secrecy in dealing with those suffering from disease which may be dangerous to the community in which they live?

I will instance what it may do. A young man called at the surgery; the medical man informed a sister that he was afraid her brother was suffering from consumption, and that it might be advisable to send him to the tuberculosis dispensary. The medical man did not see the patient again until he was far advanced in consumption. The young man admitted that he had not worked for six months. He had not claimed insurance benefit because he was afraid he would be notified as suffering from consumption. *The violation of the oath prevents the practice of the art.*

Is the profession satisfied that when their patients get to know that if they suffer from "anaemia, indigestion, wasting, and general debility," they may be in reality suffering from consumption and that they must go to the tuberculosis dispensary to be "weeded out"; will they seek the advice of the profession, or may they not nurse their illnesses in secret or seek the advice of the charlatan or quack? It may be dangerous to admit, but the confession will find an echo in the heart of many other practitioners. I have had cases where every indication was that the patient was suffering from pulmonary tuberculosis, where the patient and the mother have pleaded that if there was any doubt notification should not be made; and remembering the tragic exclamation of a young lady who had once been engaged to be married, "Who will marry a girl that has been in a sanatorium?" I have waited and the patients are now without a single symptom to indicate the previous mischief. Perhaps the diagnosis was wrong.

It can be admitted that many are indifferent to visiting a tuberculosis dispensary, as we find many who are willing to sit in a public and much advertised venereal clinic; but, as a rule, they are drawn from a type which we would not like to become characteristic of the nation. A member of an Insurance Committee admitted to me that he would seek other medical advice before he would go to a dispensary, and he had been advocating closer co-operation between the tuberculosis officer and the practitioner!

Tuberculosis officers appear to be very eager to give advice to the general practitioner; may one of the latter return the compliment by pointing out to them that the eradication of cause is even more important than the recognition of early symptom—the back-to-back houses, the overcrowding, the long working hours, the malnutrition, only to mention a few to which they could devote their energies?

Other reasons and other proofs must be forthcoming before I will be eager to hand over the sick wolf to the tender mercies of the pack.—I am, etc.,

May 27th.

A PRACTITIONER.

THE MEDICAL PROFESSION AND THE MILITARY SERVICE ACT.

THE following letter has been addressed by the Council of the Edinburgh Branch of the British Medical Association, and copies have been sent to the Prime Minister, the Minister of National Service, some other members of the Government, the members of Parliament of the area of the Edinburgh Branch, and to various others:

Sir,

The Council of the Edinburgh Branch of the British Medical Association desire to call attention to certain matters in connexion with the Military Service (No. 2) Act, 1918.

They wish to do all in their power to assist the Ministry of National Service in its endeavour to make the best use of the medical profession in the present war emergency, in the interests both of H.M. forces and of the civil population. With this object they feel it their duty to approach you on this matter because, except through the Committee

of Reference, the Central Medical War Committee, and the Scottish Medical Service Emergency Committee, no one of which can claim to be representative, the medical profession has had no opportunity of expressing its views to the Government.

The Council are proud of the fact that the members of the medical profession have been conspicuous for the readiness with which they have voluntarily offered service in the interests of the nation throughout the war, and are convinced that this readiness will continue. All the more on that account, they are strenuously opposed to compulsory powers being exercised for the provision of medical attendance on the civil population. From their intimate knowledge of general practice they are convinced that serious difficulties would arise in giving effect to any such compulsory reorganization. They are, however, cordially in favour of any voluntary arrangements which it may be found possible to make for this purpose. Such arrangements should in every case be made with the sanction of the Local Medical War Committees.

They strongly disapprove of any possible intention of the authorities to exercise their powers in such a manner as to compel a medical man without giving him the option of accepting a commission in H.M. forces to make the choice between ordinary military service and the undertaking of some new work in civil practice to which he may have serious and valid objections. They hold that, as in the past, no medical man should be conscripted into the ranks unless he has declined to accept a commission as a medical officer in H.M. forces.

They are convinced that there are many medical men in civil practice, not only within the new age limit, but considerably beyond it, who would be fit and willing to act as military medical officers at home or in base hospitals abroad were they given the opportunity; but who would almost inevitably break down under the strain of increased civil medical work.

They venture to make a strong appeal for the consideration of some such alternative to the more cumbersome method of civil substitution which seems to be in contemplation. It would, it appears to them, not only be an advantage to the army by giving a wider choice of experienced men for the less onerous but highly responsible posts in the R.A.M.C., but would benefit the general population by leaving at home some of the younger men who are best fitted to bear the unusually heavy strain of civil practice.

Before, however, any further extensive call is made on the much-thinned ranks of those engaged in civil practice, the Council would like to feel sure that the War Office are using the medical officers they already have to the best possible advantage. Many reliable reports have been received showing that there are officers in the R.A.M.C., both in this country and abroad, who are not fully occupied. There are few men now remaining in civil practice of whom the same can be said.

They are strongly impressed by the severe strain imposed on the general practitioners in the winter months during the war, and in view of the further call being made for medical officers they suggest that temporary employment in the R.A.M.C. should be offered for short periods, to enable general practitioners to take their share in the heavy work abroad during the summer and to return to their practices during the winter, when their services are in less demand at the front and more urgently required at home.

Yours faithfully,

WM. BLAIR,
President.

JOHN STEVENS,
Honorary Secretary.

British Medical Association,
(Edinburgh Branch Council),

ADAPTATION AND DISEASE.

SIR,—I cannot expect the main body of your readers to be familiar with my writings, and thus Professor J. T. Cunningham's letter (p. 632) necessitates a reply. In that letter I am charged with having "the audacity to claim priority with respect to the publication of a hormone theory of heredity, and to place" his "name in a footnote together with those of Heape, Bourne, MacBride, and Dendy." What are the facts? The relevant part of my footnote runs as follows:

I do not think that I can be accused of unduly advertising my wares, or of too keen a desire to claim priority, when I have allowed sixteen years to elapse before calling the attention of biologists in general to my address of 1901 (here republished in

Part II). The conclusions then reached by me regarding metabolites and, as we subsequently became accustomed to term them, hormones, and their influence upon the germ cells, have since then been enunciated by several prominent biologists, by Heape, Bourne, Cunningham, MacBride, and Dendy, although in each case without note of my earlier contribution, which, it should be noted, appeared in a leading organ of the medical profession under a title which had no uncertain sound.¹

What I stated in 1901 was, after pointing out that agents introduced into the body from without could influence the germ cells:

Exogenous and bacterial intoxications are not the only intoxications. We recognize yearly more and more the existence of states of truly endogenous intoxication, auto-intoxication, of disturbed states of constitution due to disturbances in glandular activity, or to excess of certain internal secretions, or of the substances ordinarily neutralized by the same. Such disturbances acting on the germ cells would be truly somatogenic.

I then instanced the case of gout and the gouty diathesis, at times originating *de novo*, more often "inherited," and I continued:

Defect in bodily metabolism has led to intoxication of the germ cells, and the offspring show a peculiar liability to be the subjects of intoxications of the same order. Here what is transmitted is a constitutional state, and that constitutional state may manifest itself in more than one way, but no one will deny that this is truly inheritance of an acquired condition.

Now it is true that in 1901 Professor Cunningham's distinguished colleague at University College had not invented the term "hormone." Professor Starling brought this into the world in the course of his Croonian lectures for 1905. He introduced it in order to afford a generic term for what may rightly be termed the active principles of the internal secretions, for bodies which have a direct chemical action upon sundry tissues in contradistinction to the enzymes which have a mediate action. Granting this, it is the thing, not the name given to it, that counts. It is quite possible that some one anticipated me in the suggestion that modifications of the internal secretions may permanently influence the germ cells. Unconsciously we absorb the opinions of others. Yet all these years I have not succeeded in discovering that any one was before me in arriving at this conclusion. It will be observed that I did not claim, as Professor Cunningham implies elsewhere in his letter, the enunciation of a complete harmonic theory. Rather, I regard a purely harmonic theory as incomplete, adhering to my original presentation and holding that metabolites of more than one order—enzymes, for example, as well as hormones—are to be held effective. No physiologist can accept a hormone theory pure and simple. But the greater includes the less, just as 1901 preceded 1908.

Briefly, therefore, Professor Cunningham's "charge" is, on the first count, that I have the audacity to claim that there were students of nature before Aristotle; and, on the second, that I have the audacity to mention Galen and other naturalists in the same breath with the Stagirite.

Had Professor Cunningham moved in circles outside the biological—for instance, among artists—he would have found that it is quite a commonplace to draw the distinction between the academic upholders of tradition, and those who are impatient of the trammels of the schools. This charge of audacity takes us back in a curious manner to the academic atmosphere of the late Middle Ages, and to those who resisted the Renaissance.—I am, etc.,

London, W., June 3rd.

J. G. ADAMI.

CARE OF THE TUBERCULOUS SOLDIER.

SIR,—Major Horton-Smith Hartley in his valuable paper (p. 609) emphasizes the need of men retaining their previous occupations in better health conditions than is possible in crowded cities. The possibilities of this, however, are at present limited, but they need not be in the future, if men with the influence that he has will join in urging a bold progressive housing policy such as is proposed by the National Garden Cities Committee, of 19, Buckingham Street, Strand, W.C.2. Half a million houses will have to be built in the future, and we must demand that they be built under the best possible conditions. I am not inviting him to send these men to Letchworth, for we already have our share, but we need a multiplication of garden cities.—I am, etc.,

NORMAN MACFADYEN, M.D., D.P.H.

Letchworth, June 2nd.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on May 25th the degree of M.B. was conferred on W. J. Hart.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examinations indicated:

THIRD M.B. B.S.—W. A. Hewitson, *Emily Catherine Lewis, *J. G. Wardrop, Ruth Balfour, M. Baranov, G. Bourne, G. W. J. Bousfield, H. Carpenter, D. C. Clark, R. N. Cooper, R. M. Dannatt, W. Feldman, Marjorie E. Franklin, Eryl Glynn, H. E. Griffiths, Winifred E. Lepper, A. E. B. Paul, E. N. Ramsbottom, Violet I. Russell, G. K. Scales, Eleanor M. Sea borough, Elisabeth H. Schwab, A. Selby-Green, Charlotte A. Shields, Esie Stansfield, G. P. Staunton, T. J. Thomas, Naomi Tribe, R. N. Vakil, Phillis E. Webb, E. Wolff, H. W. S. Wright, Irene Yates, W. A. Young.

* Distinguished in Surgery.

† Distinguished in Forensic Medicine.

The following candidates have passed in one of the two groups of subjects:

Group I.—Mary N. Andrews, J. E. A. Boucaud, O. S. Martin, Irene G. Parsons, Lily D. Taylor, J. A. van Heerden. Group II.—G. E. Barker, O. D. Brownfield, G. F. Cooke, H. C. Cox, J. H. Dancy, Maud Gazdar, H. N. Hornbrook, P. Hughes, P. N. Menon, Gladys M. Miall-Smith, B. H. Pidcock.

UNIVERSITY OF ST. ANDREWS.

The following medical degrees were conferred at the graduation ceremony on June 1st:

M.B., Ch.B.—J. C. Coutts, J. Ferguson, Janet H. Hodge, J. C. McGregor, J. K. T. Mills, Jean M. Orkney, G. R. Ross, Margaret W. Shirlaw, G. R. Tudhope, Tharyan Verghese, M.D.—K. M'Leay, Captain R.A.M.C.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

On the invitation of the president and council, a representative number of surgeons in the United States Naval Service visited the college and museum on May 31st. The party was received by the president, Dr. R. McKenzie Johnston, and members of council. There were also present Major-General John Joshua Russell, A.M.S., D.D.M.S. Scottish Command, and representatives of the British navy at present on active service.

Medical News.

THE late Mr. William Hamerton Jalland, F.R.C.S., of York, left £65,225.

DR. G. ARBOUR STEPHENS has been elected chairman of the Glamorgan Poor Law Committee for the Feeble-minded which administers the Drymma Institution at Neath.

THE sixty-ninth annual meeting of the American Medical Association is to begin at Chicago on June 10th. It will be attended by several British representatives including Sir Arbutnot Lane and Sir James Mackenzie.

DR. W. NONNENBRUCH claims to have cured a severe case of botulism with serum supplied by the Koch Institute. Clinically the case was typical, and the improvement coincided exactly with the injections, three of which were given.

THE Freemasons' War Hospital No. 2, an extension of the original hospital in the Fulham Road, has now been installed in Fulham Palace, and was formally opened by its President, the Duke of Connaught, on May 31st. The accommodation provided is 100 beds. His Royal Highness commended this work of Freemasons for the wounded, and as Grand Master wished it every possible success.

OWING to the great shortage of nurses in Germany, much of the nursing and night watching has been done by other hospital employees. Cooks have nursed infectious cases, and one cook, who nursed a case of typhoid fever, passed the disease on to eleven persons through their food. The Minister of the Interior has, therefore, forbidden members of the kitchen staff of a hospital to take part in the nursing of infectious cases under any circumstances.

THE annual report of the Homes for Inebriates Association for 1917-18 contains in an abbreviated form the report by Dr. F. S. D. Hogg, resident medical superintendent of Dalrymple House, Rickmansworth. During 1917, 47 patients were admitted, 38 of whom were cases of alcoholism, and 9 were suffering from drug addiction. Nine patients joined the army immediately on leaving the home, and Dr. Hogg finds that most of those discharged who have entered one of the services have done well. More than 50 former patients are known to have joined the colours.

At its meeting in London on May 28th the President, Lieut.-Colonel D. G. Thomson, announced that the late

Dr. Maudsley had bequeathed £2,000 to the Medico-Psychological Association of Great Britain and Ireland. The disposal of the bequest will be considered by the Council at its next meeting. The annual meeting will be held in Edinburgh next month, when Colonel Keay, Medical Superintendent, Edinburgh District Asylum (Bangour Village), will succeed Lieut.-Colonel Thomson as President.

At the annual general meeting of the Society for Relief of Widows and Orphans of Medical Men on May 29th, when Sir A. Pearce Gould, president, was in the chair, it was reported that the invested funds amounted to £143,550 and the income from investments to £4,557 18s. 7d. Subscriptions and donations amounted to £317 2s., and the working expenses for the year were £267 10s. The sum of £4,292 10s. was distributed among the annuitants of the charity (48 widows and 7 orphans). Membership is open to any registered medical practitioner who at the time of his election is resident within twenty miles of Charing Cross. Relief is only granted to the widows and orphans of deceased members. At the present time the widow of a member who has an income of £100 per annum or under receives a grant of about £80 per annum, and each orphan up to the age of 16 receives £43 per annum. There are, however, two special funds which enable the directors to continue the grants to orphans after the age of 16. Further particulars of the society may be obtained on application to the secretary at the offices of the society, 11, Chandos Street, Cavendish Square, W.1.

The following provision has now been made by the Ministry of Food for the supply of extra rations to expectant and nursing mothers: Expectant mothers may receive, on application in due form to the Local Food Office, an extra ration during the last three months of pregnancy. This may consist either of two meat coupons per week or of one butter coupon per week. In districts where a milk priority scheme has been found necessary they may also obtain a priority permit for one pint of milk daily during the same period. Nursing mothers will not themselves receive any additional ration, but are entitled to use the rations obtainable for the infant, namely, the ordinary child's weekly ration of meat, butter or margarine, and sugar, and in districts in which priority schemes are in force, a priority certificate for one and a half pints of milk daily. To obtain the child's meat and food cards, application must be made to the Local Food Office on a special form.

Letters, Notes, and Answers.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atitology, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediseera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES AND ANSWERS.

STERILIZATION OF CATGUT.

"OLD MEMBER."—There are many ways of sterilizing catgut. Lister's sulphochromic method is described in Caird and Catbarr's handbook. Boiling, or Jellott's method, is usually employed, under some modification, for the proprietary brands put up in sealed glass tubes. The ether and corrosive sublimate method requires the raw gut to be soaked in ether and 1 in 4,000 perchloride for a week each. The method of choice to-day, however, is the iodine method, which is at once simple and reliable. Commercial catgut is steeped in ether for twenty-four hours and then transferred to a 1 per cent. solution of iodine in potassium iodide for eight days. It may be kept in this solution indefinitely. Before use it should be placed in sterilized water for a few minutes.

LETTERS, NOTES, ETC.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.

DISSATISFIED writes: Allow me to join in the protest against the withdrawal of bonus to those going out of benefit. I reach the age limit this summer, and have been expecting the usual payment at that time. That it should not be paid

is, I consider, a very great injustice to me and to those who have been paying their premiums for many years, and who are likewise approaching the end of their benefits, especially as the funds of the society are in a good sound state, and well able to bear the old bonus payment. I think that a special meeting of the society ought to be called to discuss and reconsider such an important decision, as I do not for a moment suppose it can have the support of the majority of its members.

A FATAL SELF-INFLICTED LESION.

PROFESSOR SANTI PUSATERI recently reported to the Royal Medical Academy of Palermo (*Il Policlinico: sezione pratica*, May 19th, 1918) a case which is of special interest owing to its extreme rarity. On May 8th, 1917, a soldier, in order to escape returning to the front, injected nitric acid into his right ear. This was followed by high fever, vomiting, giddiness, headache, and acute pain in the right mastoid region. Seventeen days afterwards facial paralysis supervened, and nearly three weeks later haemorrhage from the right ear and from the nose came on. On October 6th the tympanum was explored, and it was found that the ossicles had become disintegrated. A large amount of granulation tissue was removed and was quickly reproduced. On November 21st there was recurrence of venous haemorrhage, and the man died four days later (about 6 months after the injection of the acid). *Post-mortem* examination showed rupture of aneurysms of the carotid artery and jugular vein at a point corresponding to the lower and anterior walls of the tympanic cavity. The front surface of the petrous bone was eroded, and on the corresponding surface of the dura there was a thin layer of pus spreading towards the middle fossa of the brain and the cerebellum. The erosion of the vessels by the necrotic and suppurating process was the direct cause of death by haemorrhage, but even without this the purulent leptomeningitis would probably have proved fatal. The present war has shown that the ear is chosen in preference to other organs as the object of self-inflicted injury probably because the public, and even some doctors, think that such lesions are of comparatively little importance.

THE BILLING CASE.

THE hearing of the case against Mr. Billing, M.P., which ended in his acquittal, was conducted in such a manner as to bring to the notice of a very wide public an evil which is apparently an invariable accompaniment of civilization when it reaches the stage of luxury. As we had occasion to show some years ago, the practices of sexual perverses are defended with the utmost effrontery by a number of persons who pose as philosophers, and many of whom have undoubtedly possessed literary talents of a high order. This attitude towards an irrational vice is inexplicable to the healthy mind of man or woman, and must be classed among pathological states. The vice seems usually to be congenital—that at least we take to be the outcome of Krafft-Ebing's researches—but apparently it may be developed by example and precept in individuals of unstable sexual equilibrium who, without such stimulation, would never spontaneously have given evidence of perversion. It is probably for this reason that the majority of people consider that such lapses are best treated by police methods.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

Subscriptions to the Second Appeal.

The following subscriptions and donations to the Fund have been received during the fortnight ending June 1st:

	£	s.	d.		£	s.	d.
Dr. W. Maxwell Penny	2	0	0	Dr. Evan Jones	0	10	8
Dr. John A. Macdonald	1	1	0	Dr. Killen	1	1	0
Dr. J. J. Perkins	3	3	0	Dr. Edhir	1	1	0
The Viscount Iveagh, K.P.	25	0	0	Medical Insurance Agency			
(per Sir Rickman Godlee)				(per Dr. Haslip, chairman)	50	0	0
Dr. J. A. Macdonald (Taunton)	6	5	0	Sir Rickman Godlee	4	2	8
Sir Francis Champneys	5	0	0	Dr. A. Rowe (sale of micro-score)	1	5	0
Dr. C. Legg	0	10	6	Dr. Taylor	2	2	0
R. H. W.	20	0	0				

Subscriptions to the Fund should be sent to the Treasurer, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0	6	0
Each additional line	0	0	9
Whole single column	4	0	0
Whole page	12	0	0

As average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

A Lecture

ON

SOME FEATURES OF GUNSHOT WOUNDS OF THE CHEST.

By J. F. DOBSON, M.S., F.R.C.S.,

LIEUT.-COLONEL R.A.M.C.(T.).

SURGEON TO THE LEEDS GENERAL INFIRMARY, ETC.

THE recognition of penetrating wounds of the chest is not always easy, and the most careful examination of the chest should be made in wounds of the upper arm, neck, shoulder, and lumbar regions. The following case is very instructive in this respect:

CASE I.—Wound in Deltoid Region (Arm raised): Penetrating Wound of Chest: Haemothorax: Aspiration: Recovery.

On July 31st, 1917, Pte. G. M. was sitting in a railway carriage when a shell fell close to the train, and he felt he had been hit in the arm. He was helped out of the train, walked with assistance about 100 yards, and then sat on a form for some time. He had a little pain in the chest, and could not take a deep breath. There was no haemoptysis. The wound in the arm appeared to be trivial, and a dressing was applied.

He was sent on to hospital about fifteen miles by road. On admission there a wound was found over the insertion of the right deltoid. The bone was not injured and there was no exit wound. He rapidly became very ill with dyspnoea, haemoptysis, cyanosis, etc. With stimulation, warmth, and oxygen he improved. Dullness was present at the right base, extending up to the angle of the scapula. It was evident that while the arm was abducted the missile had passed through the biceps muscle, missing the vessels and nerves, across the axilla, and into the chest. X-ray examination showed the foreign body in the lung about the level of the angle of the scapula, midway between the front and back of the chest. The diaphragm was elevated on the right side and there was a large haemothorax. This was aspirated and found to be sterile. He rapidly improved and was evacuated to England on August 31st, 1917.

The puzzling character of the single wound low down in the upper arm is emphasized by the subsequent history of this patient. Some time after his return to England the old wound in the arm was reopened in the expectation of finding a foreign body, and this despite the fact that the missile had already been localized in the lung.

A great change has recently taken place in the method of treating wounds of the chest. Briefly the principles of treatment now adopted are identical with those governing the treatment of gunshot wounds in other parts of the body. Wounds are excised, haemorrhage is controlled, fragments of fractured bone and large and accessible foreign bodies are removed from the lung and pleura, and large open wounds are closed. If reference is made to the most instructive article by Gask and Wilkinson¹ it will be seen that the indications for early operative treatment given there cover a considerable proportion of the cases. The only cases in which operation is not advised are those in which the wounds of the chest wall are small and clean, when there is no evidence of fractured ribs, and when the foreign body retained in the chest is small. In those cases treatment on general medical principles is adopted.

The results of this early operative treatment may be studied in the articles by Gask and Wilkinson, Anderson, Roberts and Craig, Lockwood and Nixon, and others which have recently appeared. They are a striking triumph for British surgery. But there are failures, and it is to those cases in which early operative treatment has not been adopted, or in which it has not been completely successful, that I wish to draw attention.

The chief cause of failure is sepsis. This is a most formidable occurrence after early operative treatment. Such cases are detrained on the lines of communication as unfit for further transport, and the mortality amongst these is high. The following case is an example:

CASE II.—Lacerated Wound of Lung: Immediate Closure: Sepsis: Gangrene of Lung: Death.

Pte. T. O'G. was wounded by a rifle bullet on October 4th, 1917, in the right side of the chest below the angle of the scapula. At a casualty clearing station the wound was excised, and fragments of fractured ribs and the rifle bullet removed. The lung was lacerated and there was a quantity of blood in the pleural cavity. The wound was completely closed without drainage.

On October 11th he was admitted to a general hospital off an ambulance train as "unfit for further transport." He was

extremely ill. Pulse 130; dyspnoea and cyanosis. The wound was very septic with much discharge. He was considered to be beyond further surgical aid, but improved a little under treatment, and on October 13th the wound was reopened. The parietal wound was sloughing and stinking. The lung was completely collapsed and the pleural cavity filled with foul discharge and sloughs of the parietal pleura. The lacerated portion of lung was gangrenous. A silver irrigation cannula was inserted through a separate puncture and the wound drained with a large tube. He survived until October 18th.

In this instance as soon as the wound was reopened it was converted into an open "flapping" wound. It could not be resutured around a tube owing to the sloughing muscles and pleura. All that could be done was to make provision for drainage and irrigation and to pack the wound firmly with gauze.

CASE III.—Closure of Wound: Septic Haemothorax and Purulent Bronchitis: Recovery.

Pte. J. W. G. was wounded on August 1st, 1917, by a rifle bullet in the left side of the chest. The wound was explored and fragments of broken rib removed with the foreign body. There was a considerable haemothorax. It was not noted whether the lung was injured. The wound was stitched up. He was admitted to a general hospital on August 8th, from an ambulance train as "unfit for further transport." He was collapsed and cyanosed and there was extensive dullness in the left chest. The wound was reopened in part and a drainage tube inserted, giving exit to a large quantity of stinking pus. He was very ill for some weeks, purulent bronchitis of the opposite lung being a serious complication. He eventually did well, and was evacuated to England on November 17th.

These cases emphasize the danger of evacuating a case in which the chest has been primarily closed until such time as the possibility of infection has passed.

SEPSIS AFTER IMMEDIATE CLOSURE.

In what proportion of cases treated by thoracotomy and immediate closure of the chest is secondary sepsis to be feared?

Gask and Wilkinson¹ give the following figures: Sixty-seven thoracotomies for various injuries with immediate closure of the chest, followed by empyema in 22 cases (32 per cent.) and death in 19 cases (28 per cent.). In 15 of these cases the operation was performed for infected haemothorax, and in 12 (80 per cent.) an empyema subsequently developed, with 5 deaths (33 per cent.).

Anderson² tabulates the results of 58 thoracotomies with immediate closure. Secondary drainage was necessary in 12 (20 per cent.), and there were 14 deaths (24 per cent.). What proportion of the cases of empyema died is not apparent.

Roberts and Craig³ give 25 thoracotomies and complete closure, with 10 deaths = 40 per cent.. The number of cases in which a secondary drainage was necessary is not given.

Lockwood and Nixon⁴ divide their cases into two groups, before and after August, 1917. The figures refer to the latter group only. Of 82 thoracic and abdomino-thoracic cases in which thoracotomy was performed with immediate closure there were 24 deaths (29 per cent.). It is difficult to decide from a study of the statistical tables published with the paper in what proportion of cases infection of the pleura contributed to the mortality. Apparently in 5 cases only did an empyema develop. Empyema occurred in 5 cases in which no primary operation was performed, with 1 death.

Duval,⁵ whose early work in the field of thoracic surgery has done so much to stimulate other surgeons, gives details of 29 thoracotomies with 8 deaths (27 per cent.), followed by empyema in 9 cases with 2 deaths.

In all these series of cases the late mortality and empyema rates do not appear to be included. This is impossible at the present time, and probably all the facts about these cases will not be available until long after the war. But it can safely be said that the mortality and morbidity among chest cases evacuated from the casualty clearing stations is still considerable, and almost entirely due to sepsis.

The best preventive of sepsis is early and thorough operative treatment with complete closure of the chest, but there will always be a number of cases received some time after the receipt of the wound, cases in which some degree of sepsis is inevitable. In some the infection is derived from the lung, and may not be prevented by primary operative treatment, however early and thorough.

Drainage.

Can these cases be saved by drainage? Colonel H. M. W. Gray,⁶ in contrasting the results of immediate closure and drainage, gives the following figures: 198 cases in which the pleural cavity was drained, with a 50 per cent. mortality; and 57 cases of complete closure, with 29.8 per cent. mortality. He states that the operation with complete closure is therefore 20 per cent. better than the operation with drainage. I do not think this conclusion can be accepted literally, as the late, the most seriously wounded, and the most heavily infected cases would be drained.

Still the results of drainage are undoubtedly bad. Many cases succumb to sepsis, despite a free and dependent opening. This is to be prevented by treating the infected pleura and lung as other infected wounds are treated—namely, by washing the whole of the infected area with an antiseptic fluid at regular intervals—the progressive sterilization of the wound—combined with efficient drainage. I shall describe later how this may be done.

INFECTED HAEMOTHORAX.

Let us now turn our attention to those cases in which a primary operation is not performed, where a haemothorax is present, and signs of infection develop. According to Bradford and Elliott,⁷ infection of a haemothorax occurs in about 25 per cent. of cases. Henry, who carried out the bacteriological investigations in this series, found that organisms such as the pneumococcus, *B. influenzae*, and *M. tetragenus* were present in about 20 per cent. of infected cases, and that in the remaining 80 per cent. streptococci, staphylococci, and anaerobes were found. Sir J. Rose Bradford⁸ says: "It would seem that infection of a haemothorax is much more frequently derived from the skin or clothing than directly from the lung." He divides the cases into early and late infections. In the one case the infection occurs in the first few days and is undoubtedly due to organisms carried in by the missile. In the late cases symptoms may be delayed to the second or third week. The usual symptoms are increasing dyspnoea, rise in pulse-rate, elevation of temperature, etc., and in the later stages, jaundice. For the physical signs reference may be made to Sir J. Rose Bradford's paper. The cases in which urgent symptoms most rapidly arise are those in which gas develops in the pleural cavity. Marked displacement of the heart sometimes occurs with great rapidity.

These late cases of infection of a haemothorax are extremely dangerous. The patient may be in transit to the base or even to England, and if that be so he is at a great disadvantage, as very early operative treatment is necessary.

For this reason these cases require most careful watching. When treatment is required it is required most urgently. The co-operation of the physician and the surgeon is very necessary. For one thing, the condition of the opposite lung is of the greatest importance. Purulent bronchitis, a contralateral haemothorax, or pneumonia may be present, or pericarditis. Gask and Wilkinson mention a case in which a plug of blood and mucus had been aspirated into the bronchus of the opposite lung, death occurring from respiratory failure when the affected side of the chest was opened.

Diagnosis of Infected Haemothorax.

When symptoms suggesting infection arise the chest must be explored to determine the sterility or otherwise of the haemothorax. Valuable information is frequently obtained, but a negative report is not always reliable, and if too much importance is attached to these findings necessary treatment may be delayed. If the patient's symptoms suggest that infection has occurred the chest should be opened. Radiography, to determine the amount of fluid, position of missile, etc., is of the highest importance, but it must not be allowed to delay treatment.

Treatment of Infected Haemothorax.

Preliminary aspiration may be resorted to in very desperate cases, but the serious condition of the patient is only in part the result of the mechanical pressure of fluid or fluid and gas. It is largely due to septic absorption. If the patient is relieved an operation should be performed as soon as possible.

Drainage of the Chest.

This may be performed in one of two ways:

1. Resection of a short length of rib, and insertion of a drainage tube under local anaesthesia. This is the method usually adopted.
2. Thoracotomy under local or general anaesthesia. Resection of a considerable length ($\frac{1}{2}$ to 5 in.) of rib, preferably the eighth, insertion of a spreader (Tuffier's *Ecarteur* is very satisfactory), inspection of the chest cavity, removal of clots, fluid, foreign bodies, fragments of bone, etc., repair of damage to lung and diaphragm.

The operation is, in fact, the same as that done in the early stages for chest wounds, only it is done in the presence of established sepsis. The operation may in certain cases be followed by immediate closure of the chest, but this is only possible in the early stages of an infection, and is certainly not practicable in all. In many cases a drain must be inserted.

The disadvantage of the first procedure is that no exploration of the chest is possible, and clots, foreign bodies, fragments of bone, cannot be easily removed. Nevertheless, in certain cases, this is all that can be done at the time. In some cases a more extensive thoracotomy may be required at a later date.

However established, either after a limited or an extensive operation, drainage alone is insufficient. When the infection is serious and well established it is not controlled by drainage, and the patient may succumb to sepsis. In any case free suppuration continues for a period more or less prolonged, much lymph is thrown out on to the lung, and the parietal pleura and the lung fails to expand. The cavity will perhaps close after considerable falling in of the chest wall, or the patient will be left with a chronic empyema.

Antiseptic Instillation.

Drainage should be supplemented by the progressive sterilization of the pleural cavity by the instillation of an antiseptic. This may be effected in various ways:

1. By irrigation of the cavity once or twice a day through a drainage tube. This is only satisfactory in the presence of a very small cavity. The greater part of the pleura cannot be reached.
2. By the method employed by Tuffier—namely, irrigation every two hours through a number of Carrel tubes supported on wires and inserted into the pleural cavity in all directions through the drainage aperture.

I have no personal experience of this method except in the case of small cavities. So far as I know there are no published records of the results, but they are said to be exceedingly good. The disadvantage of the method would seem to be that the dressings are difficult and tedious.

3. By filling the pleural cavity with Dakin's solution every four hours through the drainage tube, the patient lying on the sound side, the fluid being siphoned off at the end of two hours. (Campbell's method.⁹)

However efficacious, this method would seem to be exceedingly tedious and very difficult to carry out in times of stress.

4. Irrigation through a special silver cannula which I have employed and which is described and illustrated in the BRITISH MEDICAL JOURNAL, February 2nd, 1918.

The cannula is used in the following way: After opening the chest a point on the chest wall towards the upper limit of the cavity is selected where the cannula may most conveniently be introduced. This is usually in the third or fourth space, about or just external to the mammary line; a small incision is made through the skin, and the cannula pushed through the intercostal muscles into the chest. The tip of the cannula should point outwards and downwards, and the instrument is fixed in position by two sutures to the skin. The original incision is then closely sutured around a drainage tube, which may be long enough to reach into a bottle of antiseptic fluid. The tube of a Carrel ampuole is then attached to the cannula, and the cavity irrigated every two hours. Hitherto I have generally used eusol, but no doubt other solutions will be as efficacious.

This is a simple and very effective device for instilling antiseptic fluids into the pleural cavity. If the cannula is judiciously placed (and in large cavities more than one can be inserted) the whole of the pleural cavity is easily exposed to the action of the antiseptic. When the thoracotomy wound is closely sutured around the drainage tube no dressings are required for several days. The tube passes out through the dressings into a bottle, and the cavity is washed out every two hours without any disturbance of the patient. The best method of fixing the drainage tube and occluding the wound around it is to pass two catgut

sutures, one on either side, through the muscles and through the wall of the tube supported by two silkworm gut stitches through the skin, also picking up the drainage tube. There is then no leakage around the tube, the dressings remain dry, and can be left undisturbed. The silver cannula is very easily inserted; washing through is quite a simple process, and is not attended with discomfort. The saving in dressings and in the nursing required is enormous.

The results of drainage and irrigation by this method are striking. The general condition of the patient improves rapidly. The amount of discharge is much lessened, and in many cases there is practically none. The lung expands quickly and undoubtedly much more rapidly than in cases treated by drainage alone.

The following two cases are examples of infected haemothorax treated in this way.

CASE IV.—Late Thoracotomy: Irrigation: Rapid Recovery.

Pte. C. N. McC. was wounded on October 9th, 1917, by a fragment of high explosive shell in the right side of the chest and head. He received no surgical treatment at the casualty clearing station. When admitted to a general hospital on October 14th there was no history of haemoptysis, but considerable dyspnoea. Haemothorax on the right side was explored, and a coliform bacillus cultivated from it. X-ray examination showed a foreign body in the upper part of the right lung, three inches above the nipple.

On October 18th thoracotomy was performed, the eighth rib being resected, a large quantity of bloody fluid evacuated, and clots cleared out. The lung was much collapsed. The foreign body was not sought for. An irrigation tube was inserted in front through a separate small incision in the nipple line in the fourth space, with a large drain behind. The cavity was irrigated every two hours with eusol. Rapid improvement in the general condition ensued. The discharge was never abundant.

On November 3rd it was noted that the lung was expanding very well. As soon as the condition of the patient permitted the scalp wound was explored and a fracture of the occipital bone found, without injury to the dura. This was dealt with in the ordinary way, and healed satisfactorily. He was evacuated to England on December 1st, there being a very small amount of discharge and the lung well expanded.

CASE V.—Late Thoracotomy: Irrigation: Rapid Recovery.

Pte. G. B. was wounded on October 10th, 1917—a through-and-through bullet wound of the left chest. He received no surgical treatment at the casualty clearing station, and was admitted on October 14th to a general hospital. He was then very ill with an evident gas-infected haemothorax, the heart being much displaced; $4\frac{1}{2}$ in. of the eighth rib were resected; the left pleural cavity was filled with foul smelling bloody fluid with gas; the lung was almost completely collapsed. A drainage tube and silver cannula were inserted, and the cavity irrigated every two hours with eusol. The patient improved rapidly; the discharge was never profuse. The temperature oscillated for some time, and convalescence was delayed by an attack of tonsillitis. The lung expanded well.

He was evacuated to England on December 1st, 1917. He was discharged from hospital early in January, 1918, and left for Australia, the wound being healed and his general condition excellent.

In most cases it becomes necessary to remove the silver cannula before the cavity is completely closed. The rapidly expanding lung presses the point of the cannula against the chest wall and causes some pain. It is as well to continue the progressive sterilization of the cavity after the cannula has been removed, by inserting an ordinary Carrel tube through the drainage wound for the instillation of the chosen antiseptic. This is continued until the lung is completely expanded. In a normal case the lung may be expected to expand rapidly and the cavity to close in a short time. Can anything be done to expedite this?

Taffier and Depage¹⁰ are of the opinion that the best way of hastening the expansion of the lung is, after sterilization of the chest cavity, to close the parietal

wound by secondary suture, leaving a pneumothorax. The results are said to be good, but I know of no published records of cases. I have not ventured to do this in any of my cases. One is hampered by the fact that it is frequently necessary to evacuate them before the cavity is sufficiently sterilized, but the expansion of the lung is so rapid that it would seem to be unnecessary in the majority of cases.

CHRONIC EMPYEMA.

Chronic empyema is a not infrequent result of infected haemothorax. It is due to failure of expansion of the lung, and may be due to imperfect drainage or the retention of a foreign body. In comparatively early cases of chronic empyema, when the adhesions tethering the lung are not very dense, they may stretch after a time and allow sufficient expansion of the lung, which, with some amount of falling in of the chest wall, will permit the parietal and visceral pleura to come into contact and so effect closure of the cavity. If this does not take place suppuration continues for an indefinite period and the patient is likely to develop amyloid disease.

Operations for Closure of Chronic Empyema.

The following are the principal operations available for closing a chronic empyema cavity:

1. Estlander's, Schede's, or Wilms's operations* aim at effecting closure of the cavity by removing the whole or portion of the overlying ribs and allowing the chest wall to fall in, on to the collapsed lung. Schede, in addition to excising ribs, also removed the thickened parietal pleura. These methods are not free from danger; it is frequently necessary to perform the operation at several sittings, and complete success is not easily attained. At the best the lung is left unexpanded.

2. By combining an osteoplastic resection of ribs with filling of the cavity by the insertion of flaps of muscle cut from the latissimus dorsi, the scapular, or pectoral muscles.

These methods are apt to be only partially successful and the lung remains unexpanded.

3. By decortication of the lung after an osteoplastic resection. The thickened vis-

ceral pleura is stripped from the surface of the lung exposed in the cavity. By releasing the lung from the compression of its dense pleural covering it is thought that its re-expansion will be favoured. In some cases this undoubtedly occurs, but on the whole the results seem to be very disappointing. Haemorrhage is sometimes severe and the lung tissue is easily torn. It is a dangerous operation and not to be recommended.

4. By separating the adhesions which bind the lung down to the chest wall.

Types of Chronic Empyema.

My experience of chronic empyemata leads me to believe that there are three main types:

1. *Localized empyema*, such as is diagrammatically illustrated in Fig. 1. In this form the lung is partially collapsed, though in contact with the costal pleura both in front of and behind the empyema. The collection of pus may be laterally, posteriorly or anteriorly situated, though rarely the latter.

2. A *more complete form*, in which the lung is much more collapsed (Fig. 2), the anterior border having receded and the organ collapsed into the paravertebral fossa. This condition may involve the whole lung, though, as a rule,

* A very full account of these operations is to be found in a paper by S. Robinson, *Collected Papers of the Mayo Clinic*, vol. vii. p. 618.

FIG. 1.

the apical portion of the upper lobe is not collapsed and remains in contact with the chest wall. This is the variety commonly met with in large chronic empyemata.

3. *Complete Collapse of the Lung*.—In this form (Fig. 3) the organ is greatly shrunken and collapsed on to the hilum; practically all that remains is a stump of tissue attached to the vessels and bronchi.

There are other, much rarer, forms—multilocular, apical, diaphragmatic, and interlobar—and their occurrence must be borne in mind.

As an empyema develops a layer of fibrin is deposited on the pleural membrane, on that portion covering the lung and that lining the chest wall. In time organization of the fibrinous layer occurs, and a more or less dense fibrous membrane is the result. The parietal and visceral pleura become thickened, sometimes to an astonishing degree. If the empyema is drained in its early stages before fibrous changes have occurred rapid expansion of the lung is the rule. But fibrous changes prevent expansion of the lung. Fibrosis may be due to delay in recognizing and draining the empyema or to failure to control the infection after drainage, with consequent persistent suppuration. As has been said, the resulting chronic empyema may be cured by operations producing collapse of the chest wall or by removing the thickened visceral

diaphragm may be separated in a similar way. Separation of the adherent lung is not usually attended by much haemorrhage; in any case this is easily controlled by irrigation.

This method of freeing the lung is only possible in the types of empyema depicted in Figs. 1 and 2. When collapse of the lung is absolutely complete, as illustrated in Fig. 3, the cavity can only be closed by an extensive osteoplastic operation.

The following cases are examples of chronic empyemata treated in this way:

CASE VI.—*Chronic Empyema treated by Stripping Thickened Pleura: Recovery.*

Pte. T. W. was wounded on September 15th, 1917, by shell fragment. An infected haemothorax was treated in the casualty clearing station by resection of a portion of rib (ninth) and drainage. There was continuous discharge for a month.

On October 14th, when admitted to a general hospital, he was very anaemic, with rise of temperature, poor pulse, and much stinking discharge. The whole of the left chest was dull except at the apex. X-ray examination showed a foreign body in the lower lobe of the lung.

On October 18th thoracotomy was performed, 5 in. of the eighth rib being resected, and a large quantity of foul pus evacuated. The cavity occupied two-thirds of the pleural space and the lung collapsed into the paravertebral fossa. There was a sinus in the lower lobe of the lung leading to the foreign body, which was removed (a piece of high explosive

FIG. 2.

FIG. 3.

pleura covering the surface of the lung exposed in the cavity. No doubt the thickening of this portion of the pleura is a factor in preventing expansion of the lung, but it is not the only or indeed the chief factor. This expansion is prevented by the firm adhesions at the points marked A and B in Figs. 1 and 2. It is the fixation of the lung at these points which prevents expansion. At A and B the adhesions are generally very dense and firm, but beyond these points—in the areas figured A to C, B to D—adhesions are much less dense. If these barrier adhesions at A and C are separated the lung will expand. It seems probable that the limited success which has attended the operation of decortication is not due to the fact that the removal of the thickened visceral pleura has permitted expansion of the lung, but is the result of the undesigned separation of these barrier adhesions. The object of the operation for chronic empyema should be to close the cavity by effecting expansion of the lung, and this can be done by dividing these barrier adhesions at the points marked A and B on the diagrams. In fairly early cases these barrier adhesions can be separated by the fingers; when they are very firm the scissors will be necessary. The lung should not be wounded nor should any attempt be made to strip off the thickened visceral pleura from its surface. Some immediate expansion occurs always, and in some cases the results are astonishing. Once the barrier adhesions are passed separation along the lines A to C, B to D is very easy. Adhesions to the

shell). The adherent lung was stripped from the paravertebral fossa without difficulty and with little haemorrhage, and marked immediate expansion of the lung occurred. The original wound was explored and found to drain a small loculus below the main cavity. There was considerable necrosis of the ninth rib at the site of the previous resection. The silver cannula was not inserted, as one was not available. The cavity was irrigated by the side of the drainage tube. On November 3rd it was noted that the lung was expanding very satisfactorily and that there was very little discharge.

On December 1st he was evacuated to England, with the lung expanding very well and his general condition excellent. There was still some discharge from the site of the first operation, and sequestra were coming away.

A note on the further history of this patient was received on January 23rd, 1918. The wounds were healed, and the left side of the chest was expanding very well, but there was still some flattening of the chest.

In this case the immediate results of stripping the adherent lung were very striking. The barrier adhesions were so dense and firm that it is certain the cavity would never have closed unless they had been divided, and a secondary rib resection would have been required.

CASE VII.—*Chronic Empyema treated by Stripping Thickened Pleura: Recovery.*

Pte. J. F. was wounded on November 17th, 1917, in the right chest below the nipple. The wound was excised and the fractured rib removed. The diaphragm was perforated, and a fragment of shell was removed from the liver; the wounds in the liver and diaphragm were sutured, the haemothorax

evacuated. The lung was not damaged. The chest was closed without drainage.

Aspiration was performed on November 20th, 24th, and 30th. On the last occasion pus with faecal odour was evacuated. Aspiration was performed again on December 1st, and on December 12th he was admitted to a general hospital. He was very upset by his journey from the casualty clearing station, and was received in a state of collapse. There was an obvious empyema. The thorax was reopened, Tuffier's spreader inserted, pus evacuated, and adherent and collapsed lung stripped from the paravertebral fossa. Considerable immediate expansion of lung occurred. A silver irrigation cannula was placed in position anteriorly. The thoracotomy wound was tightly sutured around a long drainage tube. The patient was propped up in bed on a bed-rest, the drainage tube passing out through the dressings between the bands of the bed-rest into a bottle. The pleural cavity was irrigated every two hours with dichloramine-T, 3 per cent., through the silver cannula.

From the beginning there was very little discharge. The dressings were not disturbed for five days; the wound was then healed except at the point of exit of the tube. The dressings remained dry until the large tube was removed on the eleventh day and replaced by a smaller one. The silver cannula was removed and rescripted from time to time. The patient's general condition rapidly improved; the temperature, after some oscillations, fell to normal.

On December 23rd, 1917, it was noted that the right lung was markedly expanded, and that breath sounds were heard down to the level of the tube. After the silver cannula was removed the small remaining cavity was irrigated through a Carrel tube inserted through the drainage aperture.

The further progress of this case was uneventful. A note received early in February, 1918, was to the effect that his general condition was excellent, and the lung completely expanded; a small sinus remained at the site of drainage.

CASE VIII.—Chronic Empyema: Repeated Thoracotomy: Stripping of Lung.

Pte. J. M. L. was wounded by a piece of shell on October 25th, 1917. The missile passed into the left chest and penetrated the diaphragm. Thoracotomy was performed at the casualty clearing station, the diaphragm sutured, and the chest closed. Laparotomy was performed, but no intra-abdominal lesion detected. On November 5th 1½ in. of rib was excised and a fragment of shell removed from the pleura. The cavity was washed out with flaine and closed without drainage. On November 9th 2 in. of rib were resected and one pint of stinking pus evacuated; drainage. On November 13th 2 in. of the third rib were removed. A cavity containing serous fluid was opened, washed out, and closed. A note on November 28th stated that the left lung was completely collapsed, and that the tube drained a large cavity.

When admitted to a general hospital on December 1st there was a large quantity of discharge and the lung was collapsed. X-ray examination showed a small fragment of shell lying beneath the inner end of the clavicle. Culture yielded streptococci, staphylococci, and coliform bacilli. Thoracotomy was performed by Major J. H. Cobb through the old wound over the seventh rib, the cavity wiped out, and adherent lung stripped; some immediate expansion occurred. A silver irrigation cannula was inserted.

On December 31st, 1917, there was practically no discharge from the cavity, but it was still of some size, and extended upwards towards the clavicle. Some expansion of the lung had occurred. The general condition was very markedly improved.

A further note of this patient's condition was received in February, 1918. He was very well, and the lung was completely expanded; a small sinus remained at the site of the first operation.

It is extremely important in every case of chronic empyema to have a radiograph of the chest taken, not only to discover the presence of a missile, but to exclude the possibility of a lost drainage tube. On three occasions in the last six months I have removed a lost drainage tube from the chest; one case was one of my own. An infected haemothorax was drained after resection of a rib under a local anaesthetic. The tube was secured to the skin by two silk-worm-gut sutures. The following day it was missing. A radiograph showed it to lie inside the chest, whence it was easily removed. In another case (a man evacuated from a casualty clearing station, and put off the ambulance train as unfit for further transport) the patient complained of great pain in the chest. Five inches of half-inch drainage tube with a safety-pin attached was extracted from the pleura. Both these cases did well.

In another case a drainage tube was removed from the track of a missile through the substance of the upper lobe of the right lung. It had probably been lost for several days. This patient ultimately died from gangrene of the upper lobe of the lung.

The question arises whether it would not be better to provide adequate drainage and to sterilize the cavity by irrigation before separating the adherent lung, which could be done at a later stage. In very septic cases, in

exhausted and debilitated individuals, and in patients with signs of incipient amyloid disease, this would no doubt be the better course.

The Late Removal of Foreign Bodies from the Lung and Pleura.

If an operation is performed for infected haemothorax or empyema the foreign body, whenever accessible, should be removed if the patient's condition will permit it.

CASE IX.—Removal of a Foreign Body in the Absence of Sepsis.

Pte. C. W. was wounded on October 8th, 1917, by a piece of high explosive shell which entered the left chest close to the nipple.

On October 14th he was admitted to a general hospital. The note stated that he had had a pneumothorax on the left side, but no active treatment had been necessary. His general condition was good. X-ray examination showed a foreign body—a long, ragged piece of shell—in the lower lobe of the left lung.

On October 25th thoracotomy was performed, 4½ in. of the eighth rib being resected. Tuffier's spreader was inserted. The foreign body was felt in the lower lobe of the lung; the lung was incised, and the foreign body extracted. The wound in the lung was sutured. Complete collapse of the lung was prevented by adhesions. The patient was not at all disturbed during the operation, the pulse remaining quiet throughout. The wound was completely closed by suture in layers—pleura, muscles, and skin.

On November 16th he was evacuated to England. The wound had healed by primary intention, the lung had expanded well, and his general condition was excellent.

The question of the necessity of removing the foreign body in such a case as this has still to be determined. I have heard it seriously advanced by an administrative officer that any foreign body, however small and wherever situated, should be removed from the chest, for the reason that no man who knows he has a foreign body in the chest ever goes back into the front line. The same can probably be said of men upon whom thoracotomy has been performed. There are definite indications—haemoptysis, abscess of lung, etc.; pain and dyspnoea are also indications, but it is not always easy to be sure when these complaints are genuine.

My thanks are due to Colonel T. Gowans for permission to publish the details of the cases mentioned. I am also greatly indebted to Captain T. S. Parkinson and Captain M. J. Stewart for their invaluable assistance.

WAR SCARS AND THEIR PAINS:

WITH SPECIAL REFERENCE TO PAINFUL
AMPUTATION STUMPS.*

BY

EDRED M. CORNER, M.C., F.R.C.S.,

MAJOR R.A.M.C.(T.F.),

SURGEON 5TH LONDON GENERAL HOSPITAL, ST. THOMAS'S HOSPITAL,
ETC.; CONSULTING SURGEON TO ROEHAMPTON.

CIVILIAN and pre-war scar tissue was made up of fibrous tissue in which there were few foci of round cells and fewer organisms. These round cells represented areas of repair and did not exist for long. In consequence they were of little importance. In war scars all these conditions were increased and exaggerated, the round cells of the inflammation being more numerous and polynuclear, the neighbouring connective tissue cells proliferating and some also becoming oedematous and distended with fluid, whilst organisms, as long as three years after the wound had healed, have been grown from the ends of the nerves in a painful amputation stump. The nerves were removed at operation and dropped straightway into a culture medium. In such ways cultures of staphylococci, colon bacilli and diplococci have

* An address delivered at the Welsh War Hospital, Cardiff.

been obtained. This war scar tissue is, then, an irritant of the first water, containing contracting fibrous tissue, inflammatory foci, varying in number, and pathogenic organisms. It is like a fire, and as the smoke from that ascends the chimney and finds its way through cracks in the bricks where the mortar is bad, so the irritation of this collection of war scar tissue ascends the stump, starting infective inflammation in muscles, arteries, veins, bones, connective tissue, and nerves. There are at least three points of importance here: the pain is of composite origin, the pain need not be of nervous origin, but from the osteomyelitis of bone or the arteritis of an artery, in which case it is folly to confine the treatment to the nerve trunks.

How do the organisms get up into the painful stump? Do they go by direct extension or are they carried up in the neural lymphatics, like the toxins in a case of tetanus? Some

FIG. 1.—An inflammatory focus of round cells from an amputation neuroma.

months ago Professor Marinesco and I were investigating the painful nerves of an officer whose arm had been shattered about the elbow, and had been amputated below the shoulder-joint. The amputation wound was well healed, and had been so for some months. No other wound was present. Not until the nerves had been removed and embedded in a paraffin block for section cutting did we discover a macroscopic piece of metal in the nerve, about the size of a pin's head. How did this metal get there? Did it enter the wound near the elbow, had it been blown past the site of the future amputation and ended up in one of the nerves of the future stump, or was it carried up by the neural lymphatic stream?

Then Professor Marinesco and I were often finding dark patches, due to some powder, on our sections, and at first these were regarded as artefacts due to our faults or carelessness, such as dust. However, some were shown to be iron dust. In addition, these powder patches were too frequent to be always our fault. Finally, it was concluded that the powder was shrapnel pulverized by the action of the body juices on masses embedded in the wounds and carried upwards by the lymph stream. Then we found particles of fibres, probably silk, also carried up into the structures, including the nerve ends, in these painful stumps. These particles varied in size and shape, and they were regarded as relics of the fragmentation by the body fluids of silk ligatures afterwards carried away by the lymph stream. Then there were the cultures of organisms.

This train of evidence is enough to teach us of the upward lymphatic stream and the irritative effect of silk; it is a kind of internal seton. That some silk is carried inward by the lymph stream and some is shed outward from abscesses, sinuses, and discharges of the wound, shows that war time scar tissue is utterly unable to encapsulate surely an unabsorbable suture. It should never be used in war wounds. The great pathological characteristic of painful stumps was the presence in them of foreign bodies, usually multiple, some put there by the enemy, and others, perhaps most, by ourselves—such as the silk.

When a nerve is divided it always regenerates. In general it regenerates so as to reinnervate the deinnervated

parts. But if the deinnervated parts have been removed by amputation then the fibres of regeneration seem to innervate all structures they meet—arteries, veins, bones, muscles, and connective tissue. As they do this they sooner or later must come across the inflammation infested scar tissue, when we have the simple algebraical equation:

$$\text{Nerve} + \text{inflammation focus} = \text{pain.}$$

The particular function of the nerve affected—motor, sensory, vasomotor, etc.—does not seem to matter.

To make this worse, as they regenerate the nerve fibres branch and branch, increasing manifold the chances of trouble. No one can do more than delay regeneration, which is like the flow of a river. None can stop it. The lesson is therefore that this war scar tissue must be done away with before, at least, much regeneration can take place. This is to be accomplished by heat, light, x ray, radium, vibration, electricity, and ionization. The duty of carrying it out belongs to a special, not a general, hospital.

Should the regenerating fibres encounter an obstruction, they pool up like a river, forming a tumour—a *regeneration neuroma*. Then they flow on.

If this infective scar tissue is not removed by art or craft, reamputation will become necessary, involving a serious loss of power and usefulness to the patient. This reamputation must be done much higher, as the following case shows: A man had had an amputation just above the knee. He had an obstinately painful stump. I removed the whole contents of Hunter's canal, up which the smoke of irritation had ascended from his wound. The internal saphenous nerve was examined microscopically 6 to 8 inches above the amputation. It showed signs of infective inflammation. It would have been very hard on the man to amputate above the inflammation. Such a case is only too likely to prove unsatisfactory, as there were no clinical signs to guide the surgeon—such as a swollen tender painful nerve. One must never judge harshly. Not all have played games and learned to deny self for the benefit of the whole—true team work. How, then, is such a case usually to be judged? The team who worked on the patient are judged harshly.

FIG. 2.—An inflammatory focus in the midst of a new formation of nerve fibrils.

FIG. 3.—The infected contents removed from Hunter's canal.

This should not be. Often before fitting an artificial limb a stump appears all right. To fit an artificial limb or apparatus is sometimes like putting a poker into a fire. It stirs it up to a blaze, making patent its irritations and imperfections.

In the nerve end the irritation may

cause arteritis, endarteritis, phlebitis, lymphangitis, and thrombosis in the intraneural vessels. The irritative process travels up more freely and further along the vessels than along the nerves. The neuromata on the inner side of arm stumps illustrate this. Therefore should the vessels be cut short at every amputation.

A CASE of intussusception in the jejunum 10 inches from its commencement, due to an adenoma of an accessory pancreas, is reported by Benjamin (*Ann. Surgery*, 1918, lxvii, 293). There was a cauliflower-like mass 2 by 1½ by 1 in., projecting from the mucous membrane by a stem. The literature of accessory pancreas is summarized, and 17 other cases in the jejunum are collected from various sources. Though it is recognized that an accessory pancreas by traction may produce a diverticulum of the intestine, it does not appear that an intussusception has been previously reported.

THE EMERGENCY TREATMENT OF WOUNDS.

BY

LIEUT.-COLONEL A. J. HULL, F.R.C.S., R.A.M.C.

It has been abundantly proved by the experience of war that wounds treated by excision heal in many cases by primary union. Further, the fact is established that even when primary union does not occur the more serious types of infected wounds are avoided by this measure, provided the wound is so treated at a suitable time. Anatomical considerations, of course, prevent complete excisions in many cases.

The successful treatment of wounds depends upon the stage at which the wound comes under treatment. Wounds, fortunately, pass through a pre-inflammatory stage, and during this stage it is possible to remove the infected tissues, leaving a non-infected wound. Carrel has shown that a wound passes through a fairly definite chronological sequence. During the first few hours following its infliction a wound is comparatively clean, judged by bacteriological tests. The smears are usually negative. The organisms have not had sufficient time to multiply in order to appear in the secretions. At the end of five or six hours organisms are frequently found in smears, and after twelve hours the wound has commenced to react. Polymorphs appear in large numbers, and bacteriological examination shows a large number of organisms; moreover, the organisms have now spread to the depths of the wound and abound in the particles of fractured bone. It follows that during the first twenty-four hours the wound is amenable to surgical treatment, and after that period an inflammatory stage appears, during which the results of excision have been very much less satisfactory.

The ideal treatment for infected gunshot wounds is to excise them during the pre-inflammatory stage—that is, within twenty-four hours of the infliction. The exigencies of war will more often than not make this impossible. The question therefore arises whether it is possible to prolong the pre-inflammatory stage.

Several observers working with flavine have recorded the appearance of the wounds, which are described as *in statu quo*. There appears to be suppression of suppuration and inflammatory reaction during certain stages of treatment. It may be possible to make use of this or a similar reagent in order to prolong the pre-inflammatory stage sufficiently to allow surgical technique to be employed during the optimum period.

The only treatment which a wound at present receives in war previous to being excised or otherwise dealt with at a casualty clearing station is the application of a first field dressing. It is true that this statement requires modification, inasmuch as it may be injuriously redressed on several occasions, thus delaying the cleansing operation; but the depths of the wound, the shattered fragments of a fractured bone, the parts that really matter, receive no treatment.

In fact, in spite of the advances in surgery, particularly in the treatment of wounds, the emergency treatment is no more efficacious than it was in the days of the Trojan wars. The dressings applied to wounds before the arrival at a casualty clearing station have no influence whatever upon the infection in the depths of the wounds. Improved results of the treatment of wounds can only be achieved by some method of either excising the wound during the pre-inflammatory stage or by prolonging that stage, and research in the latter direction appears to be most desirable.

The old first field dressing appears to be totally inadequate. It is suggested that, as soon as practicable after the infliction of a wound, it should be instilled with some non-irritating antiseptic, in order to inhibit the growth of micro-organisms. Within the first few hours, unless septic foreign matter remains in the depths of the wound, pathogenic organisms are found to be few in numbers and confined to the surface of the wound.

When septic foreign bodies are retained in a wound, the growth of organisms would be enormously retarded by the presence of an inhibiting antiseptic. Septic cloth would become soaked with the reagent injected, and would become comparatively innocuous. Excision of the wounds would be carried out in due course with greatly enhanced likelihood of primary union.

Several reagents which are non-irritating inhibitors of septic organisms are available. Flavine in 1 in 1,000 solution or dichloramine-T would appear to be suitable antiseptics for the purpose. Brilliant green is frequently used (as recommended by Captain Hey) as an antiseptic stain. The wound is filled with brilliant green, which acts as a guide to infected tissue, previous to the excision of the septic area. This reagent would fulfil a double purpose if instilled into the wound at an early stage, by acting as an inhibitor of sepsis, and a guide to the septic tissue. Eusol and Dakin solutions would be too evanescent and too transient in their action for this purpose—as, in fact, they are for any wound treatment during transport.

If a 5 per cent. solution of salt be combined with the antiseptic reagent, the micro-organisms will not only be inhibited in the wound, but an outpouring stream of serum will be produced which will carry infection from the wound, and prevent the ingress of organisms.

The technique of wound instillation is of the simplest possible description. The chosen solution is instilled by means of a fine glass nozzle attached to a Higginson's syringe, care being taken to inject fluid into the depths of the wound. This treatment is certainly not beyond the scope of an advanced dressing station.

There is also indication for the use of this method in casualty clearing stations. In times of pressure a patient may have to wait a day or more before an operation can be performed. The preliminary instillation of the wound with an inhibiting antiseptic solution may make the difference of the wound being operated upon in the pre-inflammatory stage, or when suppuration has commenced. Still more desirable is such treatment when it is necessary to transfer a patient to the base from casualty clearing stations without operation.

I am not at present prepared to recommend the indiscriminate irrigation of wounds of the head and trunk as a preliminary measure, particularly if performed by unskilled hands, but I think its use in the case of wounds of the extremities, particularly compound fractures, is strongly indicated.

The use of preliminary instillation may be objected to on the grounds that the nozzle may introduce infection and that the injection of fluid may spread sepsis. A glass nozzle is easily sterilized between each injection, even at an advanced dressing station, and it is extremely doubtful if such sterilization is necessary. The injection of antiseptic fluid will not spread infection beyond the original limits of the wound, which would become infected in any case. Carrel made use of the instillation treatment in the later treatment of wounds, particularly after wound excision.

By beginning wound instillation within an hour or so we are treating a wound which is bacteriologically as sterile as an excised wound, and but for the tissue necrosis which follows gunshot wounds the early instillation of a suitable antiseptic might replace wound excision.

TEMPORARY CAECOSTOMY IN RESECTION OF THE DISTAL PORTION OF THE COLON FOR NON-OBSTRUCTIVE CONDITIONS.

BY

GORDON TAYLOR, M.A. ABERD., M.S., B.Sc. LOND.,
F.R.C.S., MAJOR R.A.M.C. (T.C.),
SENIOR ASSISTANT SURGEON, MIDDLESEX HOSPITAL, ETC.

THIS note has been written to draw attention to a little surgical manoeuvre which has been of service to me in cases of resection of portions of the distal half of the large intestine. This step in the surgical technique of excision of any portion of the large bowel between the splenic flexure and the sigmoid colon I learnt in the course of conversation with a very distinguished Scottish surgeon who employed it, but in France I have met with very few surgeons who appeared to be familiar with the procedure, either in theory or in practice. It is of course established now that excision of portions of the large intestine for gunshot injury in the "forward area" is only

rarely indicated; and, indeed, in the few papers upon gunshot wounds of the abdomen which have been sent to me by my surgical friends, or to which I happen at present to have access, there is scarcely any record of resections of the large bowel, and hardly a note of a successful case.

A. I have employed temporary caecostomy in the United Kingdom in cases of resection of the large intestine for carcinoma originating in any part from the splenic flexure to the pelvic colon. I am not referring to cases of intestinal obstruction above an operable cancerous growth, where, of course, the obstruction must be relieved by operation before any idea be entertained of extirpating the tumour, but I am advocating temporary or provisional caecostomy in cases of excision of a carcinomatous splenic flexure, descending, iliac or pelvic colon, where no obstruction exists. The opening acts as a vent for gases generated in the colon above and near the suture line, and acts as a safety valve in preventing any strain on the junction.

I am aware of the brilliant results obtained in excisions of cancerous segments of the large bowel by distinguished operators, but I submit that this little point of technique may be of value to surgeons of ordinary dexterity; it has certainly added to my mental comfort in the treatment of these cases, and it has as certainly promoted the convalescence of the patients.

B. I have also on several occasions made use of temporary caecostomy when operating in the United Kingdom to close a proximal inguinal colostomy performed in France for some severe gunshot injury of the rectum. Opinion is not yet finally settled as to the best means of closing an inguinal colostomy, but I have personally usually performed an intraperitoneal operation, excising the "spur" and practising end-to-end union of the bowel. In such cases, as in those of excision of a carcinoma, I have found temporary caecostomy to be a measure of safety. It might appear to be a retrograde step to substitute a stoma in the right iliac fossa for one of the left side, but if the caecum is simply anchored to the parietal peritoneum the opening closes readily enough, especially if the drainage tube in the caecum be inserted after the manner of a Senn's gastrostomy. I have never had to undertake any operation to close a caecostomy performed in this way, and the stoma generally closes in ten days to a fortnight.

C. Excision of portions of the distal colon for gunshot injury. It is an axiom of military surgery that in the cases of gunshot wounds of the bowel the least possible should be done, and that suture should be preferred to resection unless the latter is inevitable. The whole experience of the surgery of this war has demonstrated that suture suffices in the large majority of cases of injury to the colon; by reason of the size of this portion of the intestinal tract its wounds are mostly of the nature of perforations or tears, and the bowel is rarely completely divided. Moreover, the absence of numerous loops and coils makes multiplicity of wounds of the colon uncommon when compared with their frequency in the small intestine. Nevertheless, I do claim that there are certain cases of gunshot injury of the large intestine where a resection of the damaged portion is indicated, more especially when infarction of the bowel is present. Further, in some cases where the wound of the large intestine has been of such magnitude or difficulty of approach as to suggest the formation of an artificial anus, recourse might well be made to excision and suture, when the high mortality of the colon anus is borne in mind. The adoption of this procedure would, of course, be influenced by the general condition of the patient.

If excision is to be practised let the removal be free, and let the bowel sections be planned in accordance with the dictates of general surgical experience. The wide removal of damaged bowel and of the adjacent damaged and devitalized retroperitoneal tissue which the resection facilitates finds justification not only in being in keeping with the ordinary rules for the treatment of gunshot wounds by excision of the damaged area, but also by the end-results in those cases in which this more drastic operation has been undertaken. With few exceptions these have all been cases of gunshot injury to the distal portion of the large intestine, and in these the temporary or provisional caecostomy performed at the time of resection has proved to be a measure of safety. The opening has been made into the caecum at the end of the operation while the suture is suturing the skin of the laparotomy

incision. The "gridiron" method affords convenient access to the caecum, and the drainage tube is inserted like a Senn's gastrostomy. If a collodion or mastisol dressing be applied to the laparotomy wound, there does not appear to be any extraordinary risk of infection of the latter.

CASE I.—Penetrating Wound of Abdomen; Severe Wound of Caecum and Ascending Colon; Excision of Caecum, Ascending Colon and Hepatic Flexure; End-to-side Union of Ileum and Transverse Colon; Suture of Jejunum.

Pte. J. K. was admitted on November 20th, 1917, into a casualty clearing station with two penetrating wounds of the abdomen. Two fragments of shell had entered the abdominal cavity through the right flank, and the caecum and ascending colon were both badly damaged and perforated, the latter being almost completely divided. There were four wounds of the jejunum, which were sutured. Operation was performed about ten hours after the man was hit, and at the time he was in rather poor condition. The wounds in the flanks were widely excised, and subsequently vigorously treated by Carrel's method; the terminal part of the ileum, the caecum, ascending colon and hepatic flexure were excised, and an end-to-side junction performed between ileum and the transverse colon. The patient made a good recovery and was evacuated to the base, and I last heard of him in an unsolited letter from the medical officer in charge of a Red Cross hospital in the South of England, telling me of the patient's complete recovery, and congratulating me on the successful case.

CASE II.—Penetrating Wound of Abdomen; Resection of Jejunum; End-to-end Union; Resection of Distal Part of Transverse Colon, Splenic Flexure, and Descending Colon; End-to-end Union; Caecostomy.

Lieut.-col. W. was admitted into a casualty clearing station in the early hours of a February morning with a penetrating wound of the abdomen, produced by a shell fragment. The piece of shell entered the left flank, completely dividing his descending colon and shattering its adjacent edges. The upper jejunum was the site of several large perforations, and its mesentery was perforated and bleeding; three feet of jejunum were resected and an end-to-end junction performed. The missile had made a large rent on the posterior aspect of his transverse colon, and passing forwards and to the right had just penetrated the anterior surface of this portion of the bowel. It was deemed safer to excise the damaged portion of the transverse colon, splenic flexure, descending and iliac colon, and an end-to-end junction was performed between the proximal portion of the transverse colon and the sigmoid flexure. The wound of entry was excised widely and "Carrelled"; a temporary caecostomy was then performed. Apart from massive collapse of the lower lobe of his left lung and some trouble with the laparotomy wound, the patient made a good recovery, and was evacuated to the base a month later, and subsequently to England.

CASE III.—Penetrating Wound of Abdomen; Perforations of Jejunum Sutured; Resection of Small Intestine; Wounds of Sigmoid Resected.

Pte. C. W. was admitted into a casualty clearing station in the early hours of a January morning with a penetrating wound of the abdomen, due to a fragment of shell. After the patient had been warmed and resuscitated for a couple of hours, the abdomen was opened, and nine or ten perforations of the jejunum were sutured, and in addition a resection of 18 in. of small intestine lower down was performed. Four wounds of the sigmoid were found, two of which were on the mesenteric border. As the bowel was in a state of infarction, the damaged portion was resected, and an end-to-end junction made. The foreign body was removed from the musculature of the left flank, and the damaged tissues widely excised; a temporary caecostomy was performed. The patient's recovery was uneventful, the caecostomy closed after ten days, by which time the rectum was acting satisfactorily, and he was evacuated to the base in three weeks, and subsequently went to England. Curiously enough, this patient's father had undergone an abdominal operation at my hands in Middlesex Hospital some few years ago.

CASE IV.—Penetrating Wound of Abdomen; Large Tear of the Iliac Colon; Limited Resection; Temporary Caecostomy.

Pte. D. L. was admitted into a casualty clearing station on November 21st, 1917, with a shell wound penetrating the left side of the abdomen. The fragment had entered the left iliac fossa in front and had passed downwards and backwards, shattering the anterior part of the crest of the ilium and emerging over the left hip. There was at least a pint and a half of fluid in the lower part of the abdominal cavity, consisting largely of blood, but also of extravasated intestinal contents. Some fourteen hours had elapsed since the patient was hit, and this fluid possessed a distinctively offensive odour. The damaged segment of the colon was resected—about 2½ in. in all—and an end-to-end union performed. The wounds of entry and exit were widely excised, the loose fragments and the damaged bone were removed, and Carrel's treatment carried out with vigour; temporary caecostomy was performed. The patient made a good recovery, and by the time he was evacuated to the base his lower bowel was acting satisfactorily, and the caecostomy had closed.

Two of these cases are of special interest, inasmuch as they are resections, not only of portions of the large intestine, but also of the small. Satisfactory accounts of these two were obtained on April 23rd.

I would reiterate that the operation of excision of a damaged portion of large intestine is by no means advocated as an alternative to suture, but as an expedient to which it is sometimes justifiable to resort. The narration of the above cases will show that they have all been of a severe type, and that two, indeed, have been double resections. The purpose of the paper is merely to show that caecostomy is a measure of safety in cases of resection, and that the latter operation is justifiable in a certain few cases of gunshot injury. These cases have been operated upon in an advanced clearing station, which in its operating theatre and in the heating arrangements of the wards bore the impress of the engineering and architectural abilities of its then commanding officer; but I have also been fortunate in enjoying the assistance of an anaesthetist and of operating theatre sisters of far more than ordinary skill.

Sir Harold Stiles has very kindly allowed me to make use of his name in connexion with this communication, and in a personal letter he writes: "Whenever I resect a carcinoma, an artificial anus, or a faecal fistula of the distal half of the large intestine, the last step in the operation consists, as a matter of routine, in stitching a small area of the caecum to the abdominal wall, so that a small opening can be made into it at the end of twenty-four or forty-eight hours." I very gratefully acknowledge my indebtedness to him for this valuable hint in surgical technique, for although I have usually made my opening in the caecum at the same time as the resection was performed, and although the minutiae of the actual operative procedure may differ, the idea I learnt in visits to Sir Harold at the Chalmers Hospital, Edinburgh.

For permission to use the notes of the military cases included in this paper I am indebted to Lieut.-Colonel E. F. L'Estrange, R.A.M.C.

THE LOCAL APPLICATION OF LIQUID GLUCOSE IN THE TREATMENT OF CERTAIN SUPER- FICIAL BACTERIAL INFECTIONS.

BY

T. H. C. BENIANS, F.R.C.S.ENG.,

PATHOLOGIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL,
TOTTENHAM.

THE object of this note is to call attention to a method of treatment which in certain conditions that I have observed has produced very good results and which is perhaps deserving of wider use.

Glucose is in frequent use in the laboratory as a bacterial foodstuff, and its application to the site of an infection might at first seem not to be in the best interests of the infected host. But it may be that there are other ways of frustrating the ill effects of the invading bacteria than by their partial destruction with disinfectants. For instance, by altering the nature of the substrate on which they are acting, their products might be rendered less harmful; or the infected region might be made more suited as a nidus for some harmless organism which would then more easily displace the pathogenic one.

The following factors have to be considered to bring about an understanding of the principle which I have tried to exploit in the adoption of this method, and these will be the best guide to its use in any particular instance in which it may seem to be indicated.

1. Almost all pathogenic bacteria are capable of fermenting glucose, some of them, however, much more slowly than others.

2. During fermentation a definite acidity of the medium is produced.

3. Many of the bacterial toxic bodies, using the term in its widest sense, are formed to the greatest advantage in a definitely alkaline medium, and the production of these substances is in some cases distinctly inhibited by the presence of glucose; diphtheria toxin is an instance in point.

4. Stinking discharges are in most cases due to the tryptic digestion of proteins, and this is a form of enzyme

action which can only go on to advantage in an alkaline substrate, and which ceases in the presence of even a slight degree of acidity. This form of digestion, as it may be called, is analogous to that which goes on in the intestine with the formation, among other stinking bodies, of indol and skatol. The formation of indol by bacteria is said to entirely cease in the presence of a very small amount (0.25 per cent.) of glucose. That, as a matter of fact, I think, must depend on whether the particular bacteria ferment glucose rapidly or whether they first commence to digest the proteins. Certainly some bacteria, as, for instance, those causing the foul smell in ozæna, will produce a small amount of indol in the presence of considerable amounts (4 per cent.) of glucose.

Bearing these factors in mind we can briefly consider the clinical conditions in which I have tried this method, or seen it tried. In these infections the bacteria are carrying on their existence outside the body—that is, on the skin or mucous membrane, and not in the tissues themselves. In a sense these conditions are analogous to the "carrier" states with which we are familiar in certain other diseases, notably in meningococcus and diphtheria infections.

Bromidrosis.—This is a condition of stinking sweat, which, as I have shown, responds rapidly to the local application of glycerin.¹ I have as yet had only one opportunity of treating a case with glucose, but in this instance it was effective, as in those cases treated with glycerin.

Ozæna.—This condition of fetid rhinorrhoea is in most cases due to a massive infection of the nasal mucosa with a specific organism, the principal characteristic of which, as far as we are concerned here, is that it grows very freely in neutral broth, producing much indol and a very foul smell. It grows with difficulty in acid broth (+30 and upwards) and there is no smell and no production of indol. It grows fairly well in 4 per cent. glucose broth without any smell, and with a gradual production of acidity, and in this culture, as in the acid cultures, it rapidly dies out. A considerable number of cases of this condition have been treated by Mr. C. H. Hayton at my suggestion both with glycerin and with glucose, by swabbing over the mucosa of the nose once or twice daily with a 25 per cent. solution, with the result that the secretions of the nose have become acid, and the specific bacilli have been to a large extent, in some cases completely, killed out, and replaced by staphylococci and streptococci, the foul smell and the incrustation of the nose clearing up concurrently. I am at present only vouching for the principle of this method of treatment, which seems to hold the elements of success. The final results as to permanency of cure or mere alleviation of symptoms in these cases we hope to embody in a later paper. At present glycerin has given the better results, probably on account of its special physical properties; but it is difficult to obtain.

Chronic Otorrhoea.—Mr. Hayton tells me that he has treated several old-standing cases of this condition with success. Others who have tried the method in these cases say that they have seen no improvement. Obviously the mechanical conditions here may be totally different from those met with in a mere mucous membrane infection.

Chronic Vaginal Discharge.—At the Tottenham venereal clinic, in conjunction with Mr. E. Gillespie and Mr. F. L. Provis, I have had the opportunity of observing and treating a number of cases on this principle. Most of them were long-standing instances of persistent discharge not reacting to disinfectant douches. Some were known to be of gonococcal origin, in some there was no proof that they had had this infection at any time, and the condition seemed to be due more to the faulty anatomical conditions not uncommonly found in multiparae. The treatment was carried out by the patients themselves either by douching twice daily with a 25 per cent. solution of liquid glucose in warm water, or by the introduction nightly of a glucose pessary (25 per cent. glucose made up in a gelatin basis). We found in most cases that the purulent discharge rapidly diminished, in some cases it cleared up completely, and the vaginal secretions resumed their normal acid reaction. We are not prepared to assert that the condition can be cured by this means; some cases have relapsed after being clear some months since discontinuing treatment, some have not at present relapsed, but in any case to assert a

positive cure of a gonococcal condition is extremely hazardous. Moreover, in those cases where the anatomical conditions remain abnormal there must necessarily always be a tendency to an abnormal bacterial flora on the mucosa. Two things, however, admit of a positive statement: (1) That the patient's comfort has been increased by the diminution of the discharge; (2) that the normal acid reaction of the vagina has been restored.

In these infections of a mucous surface which, as I have said, seem to be analogous to certain other "carrier" conditions, it is highly probable that the likeliest means of cure lies, not in attempting to kill off the invaders completely lest some few escaping the killing process might find the place swept and garnished for them, but rather in attempting to restore the mucous surface to a condition in which its normal bacterial flora may multiply, and in course of time take entire possession of the field again.

In connexion with the treatment of vaginal discharge by the method advocated here, all one wishes to lay stress on is the fact of the diminution of the discharge; this most likely, though not absolutely certainly, marks a step in the right direction. Further work must show how this is effected; whether the mere acidity prevents the migration of the leucocytes through the mucosa, or whether the bacterial products that entice them out by their positive chemiotactic influence are not formed in the presence of the glucose medium I have not myself determined at present.

It needs only to be repeated that, in this as in any other form of treatment, one factor that is bound to condition success is a certainty that the medicament actually reaches the site of the infection.

THE INTRAVENOUS INJECTION OF EUSOL IN CHRONIC ARTHRITIS.

BY

HAROLD FAIRCLOUGH, M.B., B.S. DUNELM.,
HOUSE PHYSICIAN, DEVONSHIRE HOSPITAL, BUXTON.

It occurred to me that the chronic infections causing arthritis might be benefited by the intravenous injection of eusol. Fourteen cases have so far been treated; of these six were very much improved, four improved, and four were not affected. In a chronic complaint such as this it is very difficult to weigh the evidence as to the cause of the result obtained. There seems, however, little doubt that the improvement was in some of the cases directly due to the eusol.

An endeavour was made to get recent acute cases running a temperature and displaying evidence of toxic absorption. Some were, however, long-standing cases with an acute relapse. Cases are not sent to this hospital in the very early acute stage, when there is reason to think this treatment might be most beneficial. They were mostly cases that could not be classified as typically rheumatoid, and in which the source of infection was doubtful.

The solution used contains 0.5 per cent. free hypochlorous acid, and was prepared according to the receipt of James Graham, namely, 12.5 grams boric acid, and 12.5 grams chloride of lime are shaken up with 1 litre water, allowed to stand for some hours, filtered, and 8.5 grams of common salt added; dose, 100 c.cm.

CASE I.

R., aged 24, had had some pain and swelling of the right hand and wrist for six months, which spread to almost all the joints five weeks before admission. He was acutely ill in bed and was making no progress. He had irregular pyrexia up to 100°; a sore throat had started about the time of onset of the arthritis and had become much worse just previous to the time of the more acute attack. An attempt to cultivate an organism from the throat was not successful. The first injection of eusol improved his general condition very greatly. His throat was better by the next day and he began to eat for the first time for some months. He was given two more injections and made steady progress. On discharge his joints were all very much better; his right knee, however, contained fluid, but was painless. He could walk well with one stick. The temperature was normal.

CASE II.

P., aged 32, had had pain and swelling of ankles for at least four months, spreading to the knees, hips, back, shoulders, and

hands. When admitted he was confined to bed, unable to stand or walk. The knees and ankles were swollen, and in the metacarpo-phalangeal joint of the right thumb there was crepitus on movement. He had fairly widespread acne about the face. After the first injection the acne almost disappeared and the pains were slightly relieved. After the second the pains were much relieved, the swelling went down, and the acne entirely cleared up. He had one more injection and was discharged very much improved. He walked with one stick and his temperature was normal.

CASE III.

Clara G. During two years all joints had become gradually affected. Three months ago the right knee and ankle became acutely affected. On admission all joints were typically deformed and tender. There was evidence of thinning and destruction of cartilage, and some bony outgrowths. The right knee was acutely flexed and very tender, the ankle was also very swollen and tender. A skiagram of the right knee showed typical changes of septic arthritis. She had had acne of the face for three months and some pyorrhoea. After two injections she was greatly improved; her pain had gone except on movement, and the acne was very much better. The improvement in general health was also very marked. Under an anaesthetic the knee was straightened and put on extension. Her temperature rose and remained up for several days, but came down after a third injection. She had one further injection a week later. On discharge she was beginning to walk a little, suffered very little pain, and movement was returning in all her joints; even her wrists which had before been apparently fixed. The temperature was normal.

CASE IV.

J. C., aged 29; duration twenty months, gradual onset, second acute attack seven months before. On admission he walked with great difficulty with a stick. Fingers, wrists, feet, and knees were very tender, swollen, and with very limited movement. His month had twice been carefully overhauled, and was apparently healthy. He had an irregular temperature up to 100°. After the first injection he was considerably and immediately relieved, and the next day was walking about without a stick, and was better than he had been for over a year. A second injection was given, the joints steadily improved, and the disease appeared for the time quiescent. He could only stay three weeks, and was advised to return in two months. On readmission, his improvement had been fairly maintained, except for three days, during which he had acute pain. His wrists were both swollen and tender, and the left was almost fixed. He was given four injections of eusol, and made steady progress. On discharge he could run, although clumsily; he had no pain, and had better movement at all joints, though these continued to be swollen. The temperature was normal.

The above cases all did very well; their improvement was immediate and definite, and apparently due to the treatment employed. The following two cases were quite uninfluenced by the injections:

CASE V.

Dorothy L., aged 19; duration eight months, gradual onset. Acute attack in bed until admission. All joints were very tender; there was great muscular wasting. She was very anaemic, and had slight irregular pyrexia. An organism was cultivated from the gums, and a vaccine prepared, but she did not appear to respond to it, and was decidedly not improving. After five doses she was given an injection of eusol (80 c.cm.). The temperature rose to 102°; ten days later she had a second injection, and the temperature rose to 103°. She afterwards appeared to make some progress, and complained less of pain; her general condition seemed better, but the temperature continued to be elevated. It was thought she might now be in a better condition to respond to vaccine treatment, and further doses were given, but without definite result. A third injection three weeks later met with no better result. On discharge her joints were a little less tender, but she was not able to walk any better, and the disease did not appear to have been checked at all.

CASE VI.

R. E., aged 35; duration five years. He had had more frequent attacks during the last two years, and had been ill the last nine months. On admission he looked pale, thin, and ill; the fingers and wrists were mostly affected; the joints were hot and turned slightly red when very painful. He had had artificial teeth for the last six years. The temperature rose to 99.4° at night. He was given four injections of eusol, but without any relief, and was then put on a stock streptococcal vaccine. He was finally discharged only very slightly improved.

These two cases were more typical of rheumatoid arthritis than any of the others. This is of interest, as other observers have found that cases of septicaemia due to streptococci have not responded to eusol so well as those due to other organisms.

The remaining cases do not afford any conclusive evidence; two more were very much improved on discharge, four were improved quite definitely, and, in addition to the last two given in detail, two more were not benefited. Those who have done well have shown this not only by an improvement in the joint conditions and in general

health, but in a steady temperature, which has in some been very well marked.

As to the mode of action of eusol, it is obvious that the bactericidal effect must be very small. It has been shown that hypochlorous acid 1 in 2,000 serum is an effectual antiseptic, but to get that concentration about 300 c.cm. would have to be administered. In the acute cases published, in which recovery was undoubtedly due to its action, the amount was only 100 c.cm., and in one case 40 c.cm. Cordova has shown that eusol would neutralize ten lethal doses of diphtheria toxin when given in two doses, the first immediately after, and the second twenty-four hours after the injection. He also obtained similar results with tetanus toxin and with *Staphylococcus albus*. He concluded that it acted by delaying the development of bacteria and destroying their toxins, thus enabling the natural resistance of the body to assert itself, and suggested that this destruction of toxins may be in the nature of a protean coagulation. It is a moot point whether in cases of arthritis we are dealing with a toxæmia or a direct invasion of the joint by organisms, but many of the other symptoms, the general malaise, and wasting must be due to toxin action. If these can be stopped, the patient must be greatly helped, and perhaps may either find sufficient power of resistance in his own body, or may be in a fitter condition to derive benefit from vaccine treatment. The most suitable cases for this treatment will be cases with signs of chronic poisoning, as shown by the temperature, skin reaction, and general condition. Some definite improvement should be obtained the day after a dose has been given; if this cannot be definitely elicited the treatment should not be continued.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DEFORMITY OF STERNUM AND MALPOSITION OF VISCERA.

THE following is a brief description of a case of congenital absence or imperfect ossification of the body of the sternum with malposition of abdominal viscera. It occurred in a youth aged 18, who came before a National Service Medical Board for grading.

He appeared healthy except for diffuse pulsation over the precordial area. The heart sounds seemed quite normal, but on palpating the precordia the examining fingers dipped down between the sternal ends of the ribs on to the pulsating pulmonary artery or right auricle. No ensiform cartilage could be felt, but the manubrium sterni seemed quite normal in its articulations with the clavicle and first rib. Percussion revealed abnormal dullness on the left side extending downwards almost to the level of the umbilicus. On the right side normal liver dullness was completely absent. He was sent to the Lord Derby War Hospital for x-ray examination, and the report stated "Absence of sternum with malposition of viscera to the left side." Since then Dr. Fox of Warrington has kindly taken an x-ray plate of the condition, and this shows increased heart shadow to the left with greatly increased definition of the bodies of dorsal vertebrae owing to absence of the intervening sternum.

Warrington.

J. S. MANSON, M.D.

TREATMENT OF FRACTURED FEMUR.

ONE of the chief difficulties in the treatment of a fractured thigh is to avoid posterior displacement or sagging at the seat of fracture.

To overcome this displacement I make a simple addition to a Thomas's knee splint, as shown in the accompanying illustration. This support is made of iron sheeting about one-sixteenth of an inch thick and one and a half inches wide. The upper end hooks over the ring of the splint, and the lower end over the two side bars.

The iron sheeting is strong enough to support the thigh without bending, and can be arched forwards to conform with the natural bowing of the femur. It is made of sufficient length to support the condyles of the femur

without interfering with the movements of the knee-joint, and will admit of early movement of the knee-joint, especially when extension is taken by traction through the condyles of the femur.

This support can also be used with a Hodgen splint by making an extra transverse curve at the upper end instead of the hook.

The total length of the appliance is from nine to thirteen inches, as required. The distance from A to B will be

determined according to the size of the man's thigh; the depth of the curve below the line adjoining A and B will be two and a half to three inches.

J. H. C. FEGAN,
Captain R.A.M.C.(T.C.).

Reports of Societies.

CORRECTION OF BONY DEFORMITIES.

AT a meeting of the West London Medico-Chirurgical Society held at the West London Hospital on June 7th, Dr. A. J. RICE-OWLEY, the President, in the chair, Captain D. McCRAE AITKEN gave an address on the correction of gross bony deformities of the lower limbs resulting from war injuries. The results obtained at the Military Orthopaedic Hospital, Shepherd's Bush, which he demonstrated by lantern slides and casts, were excellent, and bore testimony to the efficiency of the methods adopted. Captain Aitken dwelt on the necessity of allowing time for the hardening of callus before letting the patient walk without supporting appliances. Neglect of this rule resulted in gross deformities in limbs properly set at the time of injury. Delirium from intercurrent pneumonia or head injuries was no reason for neglecting the fracture, a statement which applied equally to all other intercurrent ailments. A suitable splint would permit of moving the patient bodily without disturbing the fracture. Early surgical interference was to be avoided until all inflammatory signs had disappeared, and to aid the process and improve the condition of the limb massage was meanwhile applied. Although so far sepsis had occasionally been lighted up by surgical interference there had not been any cause for serious anxiety. Fractures of the femur were put up in the abducted position with the knee extended, and traction made on the leg after reduction under an anaesthetic by strapping attached to the end of the splint. Captain Aitken held that the general alignment of the limb was the point to be considered, but that very good practical results could be obtained where, without surgical interference, the alignment of the bone could not be made perfect. He described the reversed bone-wedge method of dealing with injuries in the neighbourhood of joints whereby shortening of the limb was obviated.

Mr. TYRRELL GRAY, while accepting most of the views expressed by Captain Aitken, could not agree that the danger of lighting up septic foci was slight, and thought this militated against the reversed wedge method. In similar cases he would prefer a simple osteotomy above the injury. Major JOCELYN SWAN supported Mr. Tyrrell Gray's views about sepsis, and further criticized the method of putting up cases of fractured femur with the knee extended. He put up such cases with the knee slightly flexed, and applied extension to the knee by Beesley's callipers, to which a weight was attached. Dr. JAMES MENNELL pointed out that massage could neither light up nor disperse minute pockets of pus or latent septic foci. Any tenderness over the seat of fracture contraindicated walking exercise. The President and Mr. ASLETT BALDWIN and Mr. A. ROCYN-JONES also took part in the discussion.

Rebicus.

DIAGNOSIS IN HEART DISEASE.

CLINICAL experience as a means of accurate diagnosis of heart disease has often been found wanting. Pathological findings have too often proved that the interpretation of morbid sounds has been fallacious, and some writers have even affirmed that the average proportion of error may be assessed at 50 per cent. To what extent have modern methods been effective in reducing this proportion? In the form of a substantial volume, entitled *Diseases of the Heart: their Diagnosis, Prognosis, and Treatment*,¹ Dr. F. W. PRICE has set forth a full account of the results achieved by several trained cardiologists working at Hampstead and elsewhere, which may be welcomed as a landmark in the onward march of knowledge. Much of the subject matter has already appeared in the form of isolated papers and addresses, and, in his preface, the writer makes due acknowledgement of his indebtedness to the labours of others. The introduction of the polygraph, by means of which it is possible to record simultaneous tracings of the heart, the artery, and the vein, has opened up new lines of study and has led to a more satisfactory explanation of the symptoms produced by varying morbid conditions.

Although the main object of the book is to record and explain the clinical value of instrumental observations, the writer has not ignored the value of older methods, nor does he entirely share the enthusiasm of some other observers as to the infallibility of the newer systems.

The primary test to which all cardiac cases must be put resolves itself into the simple question of integrity of function under strain. If the test indicates any departure from normal action, then instrumental investigation should be employed to detect the cause, and in a very large proportion of cases it is found to lie in some abnormality of the neuro-muscular structures of the heart wall. Special attention has thus been called of late years to the abnormal contractions of the auricle, known at the present time as auricular fibrillation and auricular flutter respectively. Persistent irregularity of action is the characteristic of the first of these, and paroxysmal irregularity of the second. Auricular fibrillation is regarded as a specific clinical condition which can be diagnosed with certainty. It is fully discussed and illustrated in a separate chapter. Irregularity may arise from many other causes. The introduction of the instrumental methods of diagnosis, and especially of the electro-cardiograph, which is also very fully explained and illustrated, has resulted in a form of classification which has led, and probably will lead still further, in the direction of effective treatment on rational rather than on traditional lines. The book presents a comprehensive account of modern knowledge of cardiology, and the author has taken pains to indicate the points upon which most competent observers are agreed as opposed to those about which there is difference of opinion. While he duly records such opinions, Dr. Price frequently manifests his own inability to share them. A very full index renders the work easy of reference, and as a whole it may be commended as a comprehensive guide both to diagnosis and treatment.

TUMOURS OF THE AUDITORY NERVE.

PROFESSOR HARVEY CUSHING's monograph on *Tumours of the Nervus Acusticus and the Syndrome of the Cerebellopontile Angle*² is an intensive study of twenty-nine microscopically proved cases and of thirty-five probable but unverified tumours of the acoustic nerve. They are true nerve tumours, neurofibromas, neurogliomas or neurofibrogliomas, and may most suitably be spoken of as acoustic fibroneuromas. The tumour is composed of two kinds of elements, dense fibrous and loose areolar tissue with some of the characters of a glioma, and must be distinguished from other tumours arising in the cerebello-

pontile angle. Their usual origin is in the distal part of the nerve, probably from embryonic tissue rests, within the internal auditory meatus which may become dilated from absorption. The tumour extends into the cerebellopontile angle and eventually causes internal hydrocephalus. The patients, who would appear to be more often women than men, begin to suffer on an average about the age of thirty-four years, and come to hospital and operation some four years later. These patients are therefore older than those with other sub-tentorial lesions. The left acoustic nerve was more often affected, but in rare instances both nerves were implicated, usually, though not always, as part of a more or less widespread neurofibromatosis.

The symptoms occurred in the following stages: First, auditory and labyrinthine manifestations such as deafness, tinnitus, and vertigo; second, occipito-frontal pains, with suboccipital discomfort; third, inco-ordination and instability of cerebellar origin; fourth, evidence that the adjacent cerebral nerves are implicated; fifth, indications of increased intracranial pressure with choked disc and its consequences; sixth, difficulty in swallowing, awkwardness in articulation; and, finally, cerebellar crises and respiratory embarrassment. Nearly all the symptoms, except those due to the auditory nerve, may vary from time to time in a much greater degree than in the general run of cerebral tumours.

The clinical diagnosis can be made with reasonable certainty only when auditory symptoms definitely precede the evidence of implication of other structures in the cerebellopontile angle. The differential diagnosis is fully considered, and the surgical treatment by a "cross-bow incision," which gives a bilateral cerebellar exposure, is described in detail.

This original study of clinical and pathological material has been carried out on the same lines as the brilliant author's well-known work on the pituitary, and, like it, marks a definite advance in knowledge.

RADIOLOGY.

MORTON'S *Textbook of Radiology*³ has now reached a second edition. In all its main features it is essentially unaltered, but certain revisions of the text have been made, it has been expanded by some fifty pages, and the number of plates and illustrations considerably increased. Quite one-half—the first—is given up to a description of the apparatus required for x-ray work; the second half deals with the various conditions in which radiography is valuable, and describes the technique to be used in order to obtain successful results. The subject of x-ray therapeutics is compressed into one chapter of twenty-three pages at the end which deals mainly with the action of x-rays, the methods of measuring dosage, and the theory of filtration.

The illustrations of apparatus are good, but those of radiographs used to indicate various pathological conditions are uneven, and hardly come up to the standard which is desirable. Those of the stomach after an opaque meal are—even allowing for the loss of detail in reproduction—for the most part unsatisfactory, and fail to indicate the modern possibilities of this method of demonstrating various pathological conditions of this organ.

The author states in his preface that his aim has been to produce a guide to those taking up radiography for the first time; with this in view he has been content to indicate conditions most commonly met with in which an x-ray examination is essential, and has devoted a considerable portion of his book to apparatus, and especially to the state of the x-ray tube. Recognizing this, it may be said that he has produced a book which forms an admirable introduction to the subject, and one which should be useful to a beginner.

NOTES ON BOOKS.

ERRORS and defects of movement after war wounds have exercised, and will continue to harass, those who have them in hand till the last pension has been paid. The earlier our ideas of the underlying physics of defective movement are put upon a clear basis the better, and there

¹ *Diseases of the Heart: their Diagnosis, Prognosis, and Treatment by Modern Methods.* With a chapter on the Electro-cardiograph. By Frederick W. Price, M.D., F.R.S. Edin. London: H. Frowde, and Hodder and Stoughton. 1918. (Demy 8vo, pp. 472; 245 figures. 21s. net.)

² *Tumours of the Nervus Acusticus and the Syndrome of the Cerebellopontile Angle.* By Harvey Cushing, M.D., Professor of Surgery at Harvard University. Philadelphia and London: W. B. Saunders Company. 1917. (Roy. 8vo, pp. 296; 262 figures. 21s. net.)

³ *A Textbook of Radiology (X Rays).* By E. R. Morton, M.D., C.M. (Trin. Tor.), F.R.C.S. Ed., etc. London: Henry Kimpton. 1918. (Demy 8vo, pp. xvi + 264; 93 figures; 36 plates. 10s. 6d. net.)

is no tongue better fitted than the French to call in aid. It is to be feared, however, that Professor BROCA, with all his reputation, has not quite succeeded in the volume he contributes to the well-known *Horizon Collection*.⁴ His diction does not lend itself easily to English eyes, though we can well believe that English ears, which, after all, are proper to the purpose, could they be employed in his clinique, would find much to profit by. The first part of the book deals with ankyloses, true and false, their origin, diagnosis, and treatment. The second part discusses non-articular lesions; cicatrices and muscular lesions, with consideration of alterations in the length, direction, and line of action of the long bones in their capacity as levers; it deals also with vicious callus and with false joints. The teaching is sound but not very enterprising.

Professor HARTMANN's lectures at the Hôtel-Dieu on war wounds and their immediate complications⁵ were delivered in the 1916-17 session, and, as might be expected from a teacher of his eminence and experience, afford a clear survey of the then state of opinion as to treatment. They will have a certain interest to the future historian of the evolution of practice during the war period, and doubtless were of high value in the education of his pupils, but at this moment it is inevitable that a hint of the out-of-date should insensibly creep over the reader. The advice seems of yesterday, and yesterday is already with the seven thousand years. The professor, however, rescues from the past some forgotten observations of no little interest, notably Larrey's description of trench foot, which leaves little to be added to-day.

⁴ *Troubles Locomoteurs consécutifs aux Plaies de Guerre*. Par Aug. Broca, professeur à la Faculté de Paris. Paris: Masson et Cie. 1918. (Cr. 8vo, pp. 155; 33 figures. Fr. 4.)

⁵ *Les Plaies de Guerre et leurs Complications Immédiates*. Par Professeur Henri Hartmann. Leçons faites à l'Hôtel-Dieu. Paris: Masson et Cie. 1918. (Roy. 8vo, pp. 203; 58 figures. Fr. 8.)

MEDICAL AND SURGICAL APPLIANCES.

A Modified Rigid Stethoscope.

LOUIS LOWENTHAL, M.D. (Hampstead), writes: For some time past I have been using the monaural stethoscope, which I have modified in such a manner as enables me to hear through it with both ears at the same time. The instrument consists of an ordinary monaural stethoscope in two parts, to which is attached a piece of indiarubber tubing about 16 in. in length. This is connected at the earpiece and communicates with the bore; at the free end of the rubber tubing is a comfortably fitting earpiece. When in use the small free earpiece is inserted into the ear furthest away from the examining side. The stethoscope is placed in position on the chest and used in the ordinary manner. The advantages of this instrument over the single stethoscope are that both ears are engaged, and the examiner can better concentrate his attention since extraneous sounds are prevented from reaching the otherwise unused ear. I have found it especially useful for examination of the heart; the sounds, both normal and pathological, are clear and distinct, being carried direct to the ear through the short, straight stem. Messrs. Allen and Hanburys have designed for me the pattern which I use.

THE FUTURE OF THE MEDICAL PROFESSION UNDER A NATIONAL HEALTH MINISTRY.

The discussion on this subject at the Royal Society of Medicine was concluded on June 5th.* Sir RICKMAN GODLEE was in the chair.

Sir BERTRAND DAWSON said that Sir Watson Cheyne and others had suggested that for the present the profession should confine itself to advocating a Ministry of Health, but that he considered would be an extremely unwise course to pursue. By all means let the need for such a Ministry be urged, but the success of the profession in the future would depend, not only upon the establishment of a Ministry of Health, but upon the policy pursued by that Ministry. The Insurance Act aimed far too much at securing the profession's material interests, and in consequence disregarded too much its ideals; that mistake must not be repeated. One of the first objects of a Ministry would be to co-ordinate a large number of existing departments, two of which would be chief, namely, the Local Government Board and the Insurance

Commissioners. These two bodies represented very important interests, but it was desirable that the Ministry should represent a balance of professional interests, including ordinary general practice, various organized public services, academic medicine, and research, as well as the work gathered under the two Government departments mentioned. The term "state service" was a bogey to some, but there was nothing new in state service, and it was, indeed, because the existing state service had become so ungainly in its proportions that the necessity for re-organization had become apparent. He believed that a whole-time salaried state service for all would ruin the profession; it would remove the stimulus of rivalry, lead to intellectual stagnation, and medicine would become a machine without a soul. But the profession could equally be crushed by having mechanical routine so heaped up around it that the individual was left with little opportunity to exercise his personal initiative or to put his soul into his work. While it was still too early to think out schemes in detail, it was evident that there must be (1) an approximation between preventive and curative medicine, both from the point of view of education and organization; (2) encouragement to the general practitioner by way of the provision of fabric and equipment; (3) the development of institutional treatment. He favoured a system of part-time service.

Dr. CHARLES BUTTAR asked why the profession should press for a Ministry of Health. Was it on account of some supposed benefit the profession would derive from the existence of one King Stork instead of many King Logs? Would they leap into the millennium, or would they not find that the more these things changed the more they remained the same? The failure of the Insurance Act and other attempts at state control was due to the existence of a certain number of free and more or less independent practitioners who refused to put themselves under such control, and this section would always have to be reckoned with. His own view, perhaps an unpopular one, favoured the full encouragement and development of voluntary methods, as against either a complete system of state control which would extinguish the voluntary principle, or a partial system on the lines of the Insurance Act. A large measure of organization and co-ordination could be secured on voluntary lines. He wished to see a small body of men formed, representing the Royal Colleges, the Universities, and the British Medical Association, to discuss the proposals and elicit the collective opinion of the profession as far as possible; but above all to guide the medical profession in a statesmanlike way with regard to its future.

Mr. V. T. GREENYER said that the public must be satisfied whether the profession was or not, and he foresaw difficulties under a state scheme owing to the section of people who would feel themselves "above" the ordinary state clientele of the practitioner. He hoped that the public would help the profession to maintain its freedom.

Dr. J. D. CREE thought that a matter in which the practitioner might have state assistance was that of difficult diagnosis, and this could be forthcoming under a system of complete notification.

Dr. C. THACKRAY PARSONS dealt with the reform of the Poor Law medical service; and Dr. BENJAMIN MOORE reiterated his plea for state service, which he said should not be obscured by any question as to method of payment.

Major GORDON DILL, replying on the whole debate, said that the people who were averse from any change were ignoring the facts of the situation; they disregarded the great revolution which had been going on for many years and had found issue in the Insurance Act. The conditions of medical service would never again be what they had been in the past. As to a state medical service, nobody had suggested the idea of a state service *ab initio*; there were already services of the state in which the majority of practising medical men were engaged. Some had spoken as though a state service meant a service organized and controlled by outsiders; he trusted that whatever was done the organization and control would remain in the hands of the profession.

On the motion of Dr. THACKRAY PARSONS it was agreed:

That this meeting, the third at which the future of the medical profession under a Ministry of Health has been discussed, request the Council of the Society to appoint a small watching committee to consider the progress of the question and report to the Council from time to time.

* For reports of the previous meetings see BRITISH MEDICAL JOURNAL of April 20th, p. 456, and June 8th, p. 653.

THE MEDICAL PROFESSION UNDER THE MILITARY SERVICE ACT.

THE Central Medical War Committee has issued this week a letter to the honorary secretaries and chairmen of Local Medical War Committees in England and Wales, dealing with the duties of the local committees and the ways in which their co-operation is desired in order that the new calls on the medical profession may be made with the minimum of hardship to the profession and of inconvenience to the public. It is pointed out that the local committees will continue to advise the central committee both in its tribunal capacity and in respect of its other duties, the Ministry of National Service recognizing that the system which has been gradually built up depends for its efficiency on the cordial co-operation between the central and local committees.

The Central Medical War Committee, acting as the formal medical tribunal, will deal with all claims for exemption from combatant service. The grounds upon which application may be made were given in full in the JOURNAL of June 1st, p. 622. All registered medical practitioners are liable to military service if:

(a) On the 18th April, 1918, they had not attained the age of 56.

(b) They are male British subjects.

(c) They have at any time since the 14th August, 1915, been in Great Britain; and

(d) They are not for the time being within the exceptions set out in the First Schedule to the Military Service (No. 2) Act, 1918.

The exceptions relate to men ordinarily resident in the Dominions abroad, members of the Forces, certain disabled men, certain rejected men, and men in Holy Orders or regular ministers of any religious denomination.

Any doctor who as an ordinary citizen falls to establish a claim to a special form of exemption on the ground of exceptional personal hardship or ill health, or of conscientious objection, will be given conditional exemption on the terms of the proviso to Regulation 24 (see p. 622). This, which is styled "standard exemption," will hold good unless and until he is offered a commission, the essential condition being that he will, if and when required, undertake such professional work as the Director General of National Service, after consultation with the medical tribunal, may offer him. The desire of the Central Medical War Committee is to secure that as large a number as possible of the members of the profession who come under the new Act shall accept this standard exemption, leaving the question as to whether they ought to be allowed to remain where they are, or to take a commission, or to undertake civil work elsewhere, to be settled later when the circumstances of each area are reviewed. A man who takes the exemption offered to him will be in exactly the same position as the great majority of those who apply for a higher grade of exemption, since it seems unlikely that more than a very few absolute exemptions can be granted.

The object is to put all the men concerned on the same footing, leaving the question of their future use to be dealt with in consultation between the central and local committees. Each individual will subsequently have an opportunity of being heard by both the local and central committees before any decision is reached as to the disposal of his services. In order to meet immediate military requirements it will be necessary in some areas to make a call for military service at once on eligible men of the class just over the former military age. The committees affected will receive due notice, and the doctors concerned will be dealt with in accordance with the new Regulations.

The ordinary procedure will be on the following lines:

(a) Doctors liable to military service will be examined medically by special travelling National Service Medical Boards.

(b) Meanwhile the Local Arrangements Subcommittee of the Central Medical War Committee will be considering from what areas doctors can be spared either for commissioned service with the forces, or for substitution work in civil practice, if and when required.

(c) The men under 56 in the areas selected will receive fourteen days' notice under Regulation 17 in order that they may if they choose exercise their statutory right to apply for exemption. With this will be sent a "certificate of protection" issued by the Ministry of National Service, identical in terms and effect with the "standard exemption" referred to above.

(d) Applications for an exemption different from the standard form will be heard by the medical tribunal.

(e) Simultaneously the Local Arrangements Subcommittee will continue its correspondence with the local committees and investigation into the circumstances of the areas.

(f) From the men neither rejected on physical grounds nor granted on personal grounds exemption different from the

standard exemption, the local committee will select those who in its opinion can be most easily and suitably spared from the area. The process will be analogous to that adopted during the past two years, the only difference being that a doctor who can be spared from his present work may be used for other civilian duties instead of receiving a commission.

(g) Doctors not satisfied with the recommendation of the local committee on their cases, or with the provisional decision of the central committee, will be heard if they so desire. At this hearing all relevant circumstances will be taken into consideration.

The object of this procedure will be to build up a reserve of doctors who are known to be available either for military or civilian work, and this reserve will be drawn upon as and when required. In order that the best use may be made of the men thus made available, all facts bearing on their aptitude, circumstances, and wishes will be noted during the various hearings and investigations.

There is thus no need for an individual doctor to take any action until after he has been medically examined, and not even then until he receives the fourteen days' notice from the Ministry of National Service, together with the certificate of protection which will be offered to every man. He need only take action then if he thinks his circumstances are so exceptional as to be likely to obtain something different from the standard exemption.

The above procedure is based on the assumption that plans must be laid for the possibility of a long war. Hence no idea can be given of the number of men between 43 and 56 who may have to be disturbed. But there is no intention of taking older men if, other things being equal, younger men are available; nor is there any intention of moving men for the sake of moving them. The aim of the central committee will be to disturb as few men as possible. How far this can be achieved will depend largely upon the extent to which arrangements can be made in urban areas for the release of men by a radical revision of the present conditions of practice, such as the institution of central surgeries, the pooling of practices, and the moving of doctors from one part of the town to another. In some cases it will be necessary to move doctors from one area to another, but this method will, for the most part, only be adopted when the central and local committees are convinced that in no other way can the men needed be released for military service.

In our article on this subject last week (p. 647), it was pointed out that where the ground of exemption is occupational the medical tribunal will be able to grant conditional exemption only. In this connexion it may be well to note that a recent Order by the Minister of National Service withdraws certificates of exemption from military service held wholly or partly on occupational grounds by men of various ages employed in a large number of occupations who are in medical categories A, B 1, and C 1, or Grades 1 and 2, or who have not been medically examined. Men thus "decertified" have no right to apply to a tribunal for renewal of exemption on occupational grounds, and their employers cannot make such an application on their behalf. Medical men are thus not alone in being unable to make individual application for exemption from military service on occupational grounds—that is, grounds of national interest.

With regard to the financial arrangements for substitute civilian medical service, the statement now being issued by the Ministry of National Service to medical practitioners, which was outlined in our last issue at p. 651, definitely says that the medical man "may confidently assume that he will not be required to abandon his own work for such service except upon terms of remuneration not inferior to those of commissioned service in the Royal Army Medical Corps." We understand that the financial aspects of national service for medical practitioners are being closely studied by a special subcommittee of the Central Medical War Committee.

THE President of the Republic of Cuba, on the proposal of Dr. Mendez Capote, Director of Public Health, recently signed a decree making compulsory the hospitalization of all sufferers from malaria who are unable to bear the cost of isolation. Foreigners refusing to submit to this ordinance will be expelled from the island.

At the fourth National Medical Congress, recently held at Havana, it was decided to form an anti-venereal league in Cuba. At the same meeting resolutions were passed urging the formation of a league against malaria, hook-worm disease, and rural typhoid. The work will be carried out under the direction of a committee of management comprising the leading bacteriologists in Cuba. The league will have an official organ, entitled *El Eco Científico*.

British Medical Journal.

SATURDAY, JUNE 15TH, 1918.

THE INTER-ALLIED SCIENTIFIC FOOD COMMISSION.

THE Inter-Allied Scientific Food Commission now sitting in London has already at previous meetings accomplished a good deal of work, and if its recommendations are carried out, the provisioning of allied countries will be placed on a sound scientific basis. That its recommendations will be carried out seems to be more or less guaranteed by the fact that it was established as a result of a decision of the Inter-Allied Conference held in Paris last November. The Conference directed that the inter-allied scientific commission should consist of representatives of France (Professors Gley and Langlois), Italy (Professors Botazzi and Pagliani), United States (Professors Chittenden and Lusk), and the United Kingdom (Professors E. H. Starling and T. B. Wood). It was instructed to meet periodically in order to consider from a scientific point of view the food problems of the Allies, and in agreement with the inter-allied executives to make proposals to the allied Governments. The Commission held its first meeting in Paris on March 25th, and its second in Rome on April 29th. Before its present meeting in London a representative of Belgium, Professor Hulot, was added. A memorandum upon the work of the Commission, furnished to us by the Food Controller, contains some particulars enlarging the information published in previous issues.

At its first meeting last March in Paris the Commission came to an agreement as to the minimum food requirements of the average man. It was laid down that for a man weighing 70 kilos, or 154 lb., doing average work during eight hours a day the food as purchased should have an energy value of 3,300 calories a day, but that a reduction of 10 per cent. could be supported for some time without injury to health. The Commission accepted the figures of Professor Lusk, one of the representatives of the United States, for the proportion to be assigned to women and to children at different ages. At the second meeting, in Rome, the metric ton (a metric ton is 0.9842 ton British) was adopted as the unit for estimating the weights of the various foods produced in each allied country. A "man value"—that is to say, the number of average men equivalent to the population of each of the allied countries—was established, and was taken as a basis for calculating the amount of food to be provided for the adequate nourishment of the total population of each country. An estimate was then formed of the home production of the soil furnished by each allied country in 1918-19 to serve as a basis for determining the amount of food available for men and animals respectively in each country.

It was not thought desirable to fix a minimum meat ration, in view of the fact that no absolute physiological need exists for meat, since the proteins of meat can be replaced by other proteins of animal origin, such as those contained in milk, cheese, and eggs, as well as by proteins of vegetable origin. It was, however, considered desirable to fix a minimum ration of fat; this it was decided should be 75 grams—about 2½ oz. per average man a day. It is to be

noted that the fat ration may be made up from fats partly of vegetable origin and partly of animal origin, and the Commission expresses the opinion that if the amount of fat of vegetable origin was found to be insufficient it might be necessary to maintain a certain stock of animals to make good the deficit.

The Commission has recommended that the maximum possible proportion of all cereals except oats should be reckoned in when calculating the amount of calories available for man. As to milling, it has advised that a uniform extraction of 85 per cent. should be adopted in all the allied countries; this will vary from 80 per cent. in summer to 90 per cent. in winter, and will apply to the United States only as regards their internal consumption, and then only in case of scarcity. While man should always take precedence over animals in the allocation of food by governments, it is recognized that the methods adopted for reserving the maximum possible proportion of the cereals for the use of man may vary in each country. The opinion is therefore expressed that in fixing prices it is the prices of animal products which should be limited rather than those of such vegetable products as may serve equally well for feeding men and animals. The production of veal, pork, and poultry at the expense of other food immediately available for man should therefore be discouraged, and this may best be done by fixing prices for those animal products which will make it unprofitable for the producer to feed the animals on cereals. The chief subject now under consideration is the examination of statistics which will render it possible to ascertain the calorie value of the home production of each of the allied countries. The comparison of these figures with the needs in calories of the population of each country will enable the Commission to deduce the amount of imports necessary for the maintenance of the population, or the exportable surplus, as the case may be.

The Commission has also expressed the opinion that any propaganda having for its object the encouragement of food production and of economy in the use of food should be organized and directed by men of science well acquainted with the subject. The members of the Commission itself fulfil this condition, to the importance of which we had occasion some time ago to call attention, for this elementary principle was at first neglected in this country. It appears that the truth of this principle is beginning to be recognized in Germany, where voices are being raised in favour of consultation of scientific and medical experts by the authorities.

THE PARASITE OF ICTEROHAEMORRHAGIC JAUNDICE.

NOGUCHI¹ has continued his investigations on the parasite responsible for icterohaemorrhagic jaundice, formerly called Weil's disease, and finds that there are no differential features between the Japanese, the European, and the American strains. The Japanese observers, Inada and his collaborators, described the organism as a spirochaete with several irregular waves, the entire body being dotted with alternate bright and shadowy portions, and gave it the now widely familiar name of *Spirochaeta icterohaemorrhagiae*. Hübener and Reiter, who recognized these appearances, believed that the organism had a series of minute knots, and hence called it *Spirochaeta nodosa*. Noguchi's careful observations show that the organism differs morphologically and in resisting the

¹ Noguchi, H., *Journ. Exper. Med.*, Baltimore, 1918, xxvii: 575-625.

destructive action of a 10 per cent. solution of saponin from all previously described spirochaetes, and he therefore places it in a separate genus under the name *Leptospira icterohaemorrhagiae*. The creation of a new genus may also, it is thought, facilitate a more exact morphological description than has hitherto been possible, as the vague use of the term spirochaete has indiscriminately covered at least six large genera of spiral organisms.

It is interesting to note that Noguchi's discovery of the organism in rats in America, where the disease has not been established as occurring in human beings, has been recently paralleled in this country by A. C. Coles,² who recognized this infection in nine out of a hundred rats examined, and in Tunis by C. Nicolle. In these countries, therefore, epidemics of jaundice due to this cause may be anticipated—and, indeed, may have already occurred—but, so far, the proof has not been established by the discovery of the organism.

Noguchi has also examined the cultural conditions of the organism, and finds that an animal or human serum is essential, but that the cultural value of different animal serums varies very considerably; that the reaction of the medium is an important factor, the most favourable being a slight degree of alkalinity; that the organism is an obligatory aerobe; that it grows best at 30° to 37° C., but is unable to grow in urine and does not survive more than twenty-four hours unless the urine is neutralized or rendered slightly alkaline. The faeces of normal or jaundiced persons destroy the organism within twenty-four hours, and in polluted water and sewage it does not remain alive for more than three days. It is therefore improbable that the spirochaete can survive long after it leaves its host, and to explain cases of human infection in which the carrier rodents are not in contact with man, the question of insect vectors has been taken up by Reiter, who obtained negative results with certain biting flies, fleas, and bed-bugs, and by Noguchi, who found that the larvae and adults of the *Culex* mosquito, the larvae of the house-fly and the bluebottle, wood ticks, and leeches failed to become carriers when fed on infected guinea-pigs or their organs. There are therefore further points to be established about the life-history and spread of this spirochaete.

THE RATE OF REFLEX NERVOUS DISCHARGE.

THE meeting of the Royal Society on June 6th was occupied in hearing and discussing an important paper by Mr. N. B. Dreyer and Professor C. S. Sherrington, F.R.S., on the brevity, frequency of rhythm, and amount of reflex nervous discharge as indicated by reflex contraction. The observations upon which the paper was founded arose out of an investigation undertaken for the Army Tetanus Committee, of which Sir David Bruce is chairman. The authors found that a single momentary stimulus of moderate intensity, such as a break-shock, even though not far above the threshold value of stimulation, applied to the afferent nerve of a spinal reflex centre, not uncommonly evoked from that centre a repetitive series of volleys of motor impulses. It tended to do so more as the stimulus, within limits, was increased in intensity, but the state of the reflex centre at the time was also a decisive factor. The rhythm of repetition of volley discharges from the spinal reflex centre was traced, by the ordinary mechanical method, to be of synchronous rate with that of stimulation of the afferent nerve, up to a frequency of 55 a second, and by a mechanical resonance method up to a frequency of 65 a second. By a "doubling frequency" method it was shown further that the frequency-rate of the reflex

discharge had not reached its limit under a stimulation of 75 a second, but surpassed that degree, though by what amount the method did not show. The maximal mechanical power of a muscle contracting under spinal reflex action was frequently as great as the maximal which could be evoked from it by direct faradization of the motor nerve itself.

DIPHTHERIAL INFECTION OF WOUNDS.

A good illustration of the great complexity of questions bacteriologists may be called upon to answer is afforded by a recent inquiry carried out for the Canadian Army Medical Corps with respect to the presence of diphtheria and diphtheroid bacilli in open wounds.¹ The inquiry was rendered necessary by the publication last September of a report by Majors Fitzgerald and Robertson, to the effect that out of 67 cases of open wounds in men returned from the Canadian Expeditionary Force examined in a particular division between May 20th and June 7th, 1917, no fewer than 40 afforded cultures of the diphtheria bacillus. The significance of the observation was somewhat discounted by the discovery that a nurse whose duty it was to dress the suppurating amputation cases had a slight wound of the index finger which yielded cultures of *B. diphtheriae*; she could not, however, be held entirely responsible for the outbreak because other instances of infected wounds occurred in soldiers who had returned to Canada after the nurse had been taken off duty. In two or three cases the infection was discovered in men immediately on their arrival in Toronto from overseas. Characteristic membrane formation occurred in certain of the cases, and in some the virulence of the bacilli isolated in cultivation was proved by inoculation. The fact that some of the cases afforded cultures of the diphtheria bacillus immediately upon arrival in Toronto made it essential to institute an inquiry in England to determine the frequency of the presence of *B. diphtheriae*, and incidentally of allied diphtheroids, in the wounds of patients in Canadian military hospitals. The inquiry was very laborious, but the result was reassuring. Only in four out of 306 cases examined were bacilli isolated having cultural characteristics of a true diphtheria bacillus, and of these four only two were virulent. On the other hand, in a considerable number of cases diphtheroid bacilli were isolated—that is to say, bacilli which morphologically resembled the true diphtheria bacillus. As long ago as 1888 attention was drawn to the fact that a Gram-positive bacillus which might easily be mistaken for the true diphtheria bacillus was frequently present in the throat and mouth. This was at first assumed to be an attenuated strain of the virulent germ, but when more refined bacteriological tests were brought into use in which the power of bacilli to ferment sugars was tested, it was established that this non-virulent bacillus was quite distinct from the true virulent bacillus, and it received the name *B. hofmanni*. Later on many other bacilli resembling the true diphtheria bacillus were found, and at least six groups of them distinguished. Morphologically, and in the early stages culturally, diphtheroid bacilli from wounds are many of them indistinguishable from *B. diphtheriae*, and in some instances they may have the same power to ferment sugars, so that it is not justifiable to make a diagnosis of diphtherial infection of wounds either from smears alone or from stained preparations and cultural characteristics. The demonstration that the bacilli produce toxins—ectotoxins—which can only be effected by observing the result of inoculation of broth culture, is alone capable of proving the presence of infection by the true virulent *B. diphtheriae*. There is a certain amount of evidence that particular species of diphtheroid bacilli characterize particular hospitals, but none that the diphtherial infection of wounds is otherwise than uncommon among the wounded.

EPIDEMIO LETHARGIC ENCEPHALITIS.

PROFESSOR A. NETTER, who drew attention last March to the occurrence of cases of what he called lethargic encephalitis in Paris, has recently published¹ a fuller account of the subject. A number of similar cases have been seen by Professor Chauffard and other physicians in Paris and also in other parts of Northern France. The earliest cases in Paris were seen in March, and were diagnosed either as cerebro-spinal meningitis or as tuberculous meningitis. The chief symptoms were fever, somnolence, and ophthalmoplegia, so that the cases appear to belong to the same category as those observed recently in this country, and at first thought to be due to betulism. The patient at first either sleeps, or with difficulty resists the inclination to sleep, but at the same time is able to answer questions and to obey directions. Later on he becomes quite lethargic and unable to do anything, although he may wake up every two or three days to take food. Eventually the somnolence may deepen into coma. The lethargy may be varied by delirium or by convulsions, and the condition may last for weeks or months and be complicated by paralysis of sphincters and by bedsores. The commonest motor paralysis is ptosis of one or both sides, but squinting and even complete immobility of the eyes may be observed—symptoms which point to external ophthalmoplegia of nuclear origin. Loss of accommodation and of the light reflex may occur, and nystagmus is common. The paralysis may extend to the face, the palate, the tongue, the larynx, and the pharynx. There is no actual paralysis of the limbs, but often inco-ordination, trembling, or even clonus or contractures. Fever generally lasts only for a few days, and the diagnosis of encephalitis rests upon the absence (as a rule) of contracture, of Kernig's sign, of irregularity and slowing of the pulse, and on the fact that the cerebro-spinal fluid obtained by lumbar puncture is normal. The mortality Netter estimates at about 50 per cent., but some of the cases which appear most desperate recover. Examination of the brain reveals the lesions of diffuse interstitial encephalitis, which are those observed by Mott and others in sleeping sickness due to the *Trypanosoma gambiense*, though the cause, which has not yet been ascertained, of lethargic encephalitis must be different. Netter recalls an epidemic outbreak of a similar kind in Upper Italy and Hungary in 1890 to which the name "nona" was applied. Apparently cases of the same sort occurred in 1895 in many countries, including France, England, Germany, and the United States. The earliest record of an epidemic prevalence of such a disease appears to be that of an outbreak in Tübingen in 1712, which was called sleeping sickness, but though ocular paralyses were noted it is not clear that somnolence was present in the same cases. Netter gives a reference to an epidemic in Vienna in 1916-17 which appears to have presented all the symptoms of the recent cases. An inoculation under the dura mater of brain substance from one of the Vienna cases produced in a monkey a condition of somnolence which ended in death after forty-six hours. In this animal acute haemorrhagic encephalitis was present. Another monkey inoculated under the dura mater with an emulsion filtered through porcelain remained unaffected. These experiments were made by von Wiesner, who obtained cultures from man and monkey of a Gram-positive coccus; but these experiments do not seem to have been pursued. Netter rejects the suggestion that the condition is due to the same infection as produces poliomyelitis, mainly on the ground that in lethargic encephalitis the inflammatory lesions are interstitial and the cells are not involved. He also rejects the suggestion that it is due to food poisoning, and comes to the conclusion that it is a specific disease due to an infective agent not yet identified. As to treatment,

he used hexamine, which is believed to have an antiseptic effect on the central nervous system, as shortly after its ingestion formic aldehyde can be found in the cerebro-spinal fluid. He also advises intraspinal injections of serum from subjects who have recovered from the disease, a method which he found useful in poliomyelitis.

THE SOYA BEAN.

IN an article on the making of a vegetable milk from the soya bean published on April 13th, p. 430, it was said that though the bean grew freely in China, where it is indigenous, in Southern France, in Algeria, and in many parts of America, it did not take kindly to the English climate. We are informed by Mr. North, curator to the Royal Botanic Society of London, that the society has recently had so much success in growing the bean that it seems possible that its cultivation may become established in this country. Mr. North tells us that some 700 varieties are known in Eastern Asia and that one has been found which apparently flourishes here as well as in its own country of Manchuria. From an article in the *Botanical Journal* for March, 1918, we learn that the bean was brought to England in quantity for the first time in 1908, and that in the following year experiments were made at the instance of the Board of Agriculture with sixteen varieties obtained from Japan. The experiments failed because, though the plants grew well, they formed no flower. In 1910 seed was obtained from Manchuria, and some of the plants formed seed at the Cambridge University farm. When resown in 1911 the crop made little growth, and no seed was produced. Another experiment in the same year with a variety known as "early Tennessee," obtained from Quebec, was also considered to be a failure. In 1913 the Royal Botanic Society took the matter up, apparently as a consequence of a visit from the agent of a German cultivator, who wanted to form a syndicate to grow the bean. Later a dried specimen of a plant of an acclimatized race was supplied by the German agent, but all the seeds had disappeared from the larger pods; however, from several small pods thirteen seeds were obtained, which in the following season yielded plants bearing 440 seeds. From this small beginning the society succeeded in raising its stock to over 12,000 fully developed seeds. This year the plant is being grown under crop conditions in several places, and the Board of Agriculture and the Ministry of Food are interesting themselves in the experiment. The object in view is not to produce a vegetable milk, but to afford a new source of oil supply in this country. The bean, it is said, has been cultivated in China for 4,700 years, and the production of oil from it is among the most important industries of Manchuria and Japan. The residue is made into bean cheese and bean cakes, which are used for feeding cattle. The beans and products made from them have in fact become important articles of commerce. The fresh expressed oil may be used in soap-making without further preparation, and it is owing to its value in the manufacture of soft soap that it has hitherto been of commercial importance in Europe. The average percentage composition of the bean is stated to be oil 18, albuminoids 40, carbohydrates 22, cellulose 5, ash 5, and water 10. The amount of oil is higher and the albuminoids and carbohydrates lower than in the analysis we published, and it is probable that the amount of fat there given as contained in the vegetable milk was too high. In Japan the soya bean is also used for making certain condiments by submitting the beans to a kind of fermentation. At one time soy was largely imported into this country from China, and it was one of the condiments Byron recommended his fellow countrymen to take to Rome if they did not wish to starve during Lent. Whether there is any considerable importation of soy condiment at the present day we have not been able to ascertain. We are informed that a plot has

¹ *Bull. de l'Acad. de Méd.*, T. LXXIX, No. 18.

been sown this year in the gardens of the Royal Botanic Society, Regent's Park, under the direction of the council and the honorary treasurer, Sir Malcolm Morris.

THE FOOD OF THE ROMAN SOLDIER.

THE diet of the Roman soldier was on a scale very far below the liberal rations deemed necessary for modern armies. Readers of Caesar's *Commentaries* know how careful he was in all his campaigns about the *res frumentaria*. Till the period of the Roman Empire the legionary made his own bread. He roasted his ration of corn, ground it in a handmill or between two stones, then kneaded the flour into a paste with a little water, and cooked it in an oven improvised with a few tiles. He also made of it a strong vegetable soup, something like the old English frumenty (wheat boiled in milk). On this food, says Edmund Alexander Parkes, the Roman soldier marched and conquered as men of no other race have done. Sometimes, as a punishment, the ration of wheat was replaced by barley, which by the ordinary Roman was left to slaves and animals. On campaign the legionary had, in addition to his corn, a ration of meat when it could be got. Strict generals like Scipio insisted that the meat should be simply boiled or roasted without seasoning and eaten without sauce. But just as the Romans learnt the use of some weapons from their enemies, so they got from them certain culinary recipes. Thus they borrowed two kinds of sausages from the Lucani and the Falischi. The only drink allowed the Roman soldier was the *posca*, a mixture of vinegar and water, such as was given in a sponge fixed on a reed to Christ when hanging on the cross. Wine did not come into general use till the period of the Empire.

SANITATION IN INDIA.

THE task of the sanitary medical officer in India is so gigantic that sometimes it may well cause discouragement. He has to deal not only with a population very fixed in its ancient ways and with diseases common in this country, such as tuberculosis—which is, perhaps, as frequent in India as in England—but with tropical diseases such as malaria, kala azar, dysentery, and sometimes cholera. Encouragement may be drawn from the results obtained by the medical administration of Indian jails. The initiation of the work was due to a minute made by Lord Macaulay in 1835, but the first administrator who took in hand the sanitary reform of jails in India was Surgeon James Hutchinson of the Bengal Medical Service; he published a book on the *Medical Management of Indian Jails* early in 1835. It appears from a paper by Lieut. Colonel Mulvaney, published in the *Indian Medical Gazette* last year, that the death-rate from all causes in the Bengal jails in the five years ending 1847 was 75 per 1,000; in the five years 1878–82 it was still 74 per 1,000, but since then there has been a steady improvement, until in the five years ending 1917 the rate was only 20 per 1,000, and Colonel Sir W. J. Buchanan, K.C.I.E., the Inspector-General of Prisons in Bengal, is able to report that in 1917 it was only 15.8. There has also been a steady decline in the death-rate from cholera. In 1883 it was 5 per 1,000, in the five years ending 1917 it was 0.3 per 1,000; in fact, cholera, once a terrible factor in prison mortality, has for the last dozen years or so ceased to have any very notable influence on the mortality rates. A certain number of cases among newly admitted prisoners must always be expected, but through the establishment of quarantine wards in every jail the disease is prevented from spreading to other inmates.

THE "SUGGESTION" FACTOR IN TREATMENT.

IN all medicinal treatment, however appropriate and however active, there is a certain dose of "suggestion," which is not without its effect on the results. This is especially

true of the treatment of chronic diseases, in which the curative effects of drugs are not forthwith apparent. This "suggestion" only lasts for a certain period, which has been calculated by an ingenious French physician to be about three weeks. If no change be made after the lapse of this period the patient's hopes begin to falter and he loses confidence. Now, it is well within our means to continue the treatment in principle while varying the particular mode of application, and by shuffling the cards, so to speak, by altering the form of the treatment and rearranging the scheme, we can imbue the sufferer with the pleasing conviction that he has accomplished one stage and is now entering on a second. This may sound trivial, but therapeutic success is largely dependent on small details. It is an essential part of the programme to foster the patient's hopes and maintain his courage by devices which, though hardly scientific, may yet help him. Take such a disease as phthisis, for example. There are several well-thought-out methods of treatment which, in favourable cases, make for recovery. These methods comprise physiological factors that constitute the basis of therapy along with others which, like the vehicle in a mixture, are so useful as to be almost indispensable. Prolonged treatment must be monotonous, and this very monotony in the long run militates against its success. It does not require very much ingenuity to obviate this drawback. We are familiar with the remarkable effects of any new treatment of a chronic disorder if only it be applied by someone who enjoys the patient's confidence. The buoyancy begotten of hope stimulates the circulation, and individual symptoms for the time being attract less attention, so that the general effect is one of "feeling better."

THERAPEUTIC USES OF SUGAR.

AN Italian physician, Professor Lo Monaco, has recently stated that remarkable results have been obtained in tuberculosis by the intramuscular injection of solutions of cane sugar. He injects, with proper precautions to ensure antisepsis of the skin, 5 grams of saccharose dissolved in 5 c.cm. of sterilized distilled water. This quantity is given daily in one or two intramuscular injections. It is said that after three or four days the temperature falls, night sweats cease, the cough is very much lessened, and the amount of expectoration greatly diminished. It is stated by *Le Journal* that the method is to be tried at the French sanatorium for tuberculous soldiers at Bligny. The results of this trial will be awaited with interest, for the effects claimed are rather astonishing. We have not been able to find any previous record of the administration of sugar by intramuscular injection, but sugary solutions have been used by hypodermic and intravenous injection chiefly to produce diuresis, and in place of saline injections in various toxic conditions. Their use has been condemned in Bright's disease and in arterial hypertension. Occasionally febrile reaction has been observed, and this has been attributed to the existence of latent tuberculosis in such cases. According to a recent note by Dr. G. Lyon,¹ an artificial serum containing sugar was first used by Hédon, Arrons, and Jeanbrau at Montpellier; but most of the recent work has been done by Fleig, who has prepared a number of formulae, and has suggested the addition of sugar to the ordinary saline injections. Most of the formulae direct the use of glucose, though lactose as well as saccharose has also been added. The use of a solution containing both glucose (3 per cent.) and sodium chloride (0.24 per cent.) has been suggested. An isotonic solution of saccharose is obtained by using 9.25 per cent. of pure crystallized cane sugar in distilled water; a hypertonic by using 30 per cent. As sugar has a nutritive value it has been suggested that when it is necessary to instil

¹ *La Press Médicale*, 1918, No. 20.

a saline injection during an operation it may be well to replace it by a glucose solution, with or without the addition of adrenalin (10 drops to the litre).

THE WAR HOSPITALS PROVIDED BY THE BOARD OF CONTROL.

AMONG the members of the medical profession who have received the honour of K.B.E. is Dr. Edward Marriott Cooke, chairman of the Board of Control, and we may take it that this honour is in recognition of the work done in connexion with the utilization of asylums as war hospitals. Sir Edward Cooke has been largely concerned in the initiation and development, on behalf of the Board, of this scheme, under which, by the conversion and adaptation of some sixteen county and borough asylums, a like number of large and well-equipped war hospitals have been formed, providing rather more than 26,000 beds; in them more than 300,000 sick and wounded soldiers have already been treated. In carrying this scheme through the Board of Control have had the cordial co-operation of the visiting committees, medical superintendents, and staffs of the whole of the county and borough asylums in England and Wales. Without this ready help the scheme could not have matured, and it is worthy of mention that, as respects the asylums offered to the Army Council, the services of every member of their staffs were taken over, and that these have proved of great value to the military authorities.

We regret to announce the death of Mr. L. A. Dunn, senior surgeon to Guy's Hospital. An obituary notice will appear in an early issue of the JOURNAL.

Medical Notes in Parliament.

National Service Medical Boards.—Upon a question by Sir H. Nield as to whether the constitution of medical boards for examining recruits in the London district and elsewhere had been altered, Mr. Beck stated, on June 10th, that it had been found necessary to increase the number of acting National Service Medical Boards in certain districts. It was expected that it might become necessary, in cases of urgency, for temporary emergency boards to consist of two doctors. He was glad, however, to say that it had been found possible to avoid the need of constituting any board with less than three doctors, and this was the minimum number responsible for the passing of a new recruit. Sir H. Nield inquired why boards which it had been promised should consist of five medical men were reduced to three without any notification to the House. Mr. Beck replied that he must have notice of that question, but he understood that those who dealt with the matter were perfectly satisfied so long as three doctors held the examination. Sir H. Nield asked whether the attention of the Director-General of National Service had been specifically called to a circular issued by the Assistant Director of Medical Service in London reducing the board from five to three without any intimation that it was a temporary arrangement. Mr. Beck answered that attention had been called to an alleged circular which suggested reducing the medical boards to two medical men. That was objected to, and his answer dealt with that point. Mr. Hogge asked that the secret orders should be laid on the table, and whether doctors in many places had refused to accept them. Mr. Beck said that he was not aware of such refusal. The evidence he had was to the contrary, but he did not understand that there were any medical instructions of the kind. Each recruit would be examined by three doctors. Sir H. Nield asked whether recruits at the close of their medical examination at 52, Conduit Street were being requested to put their signature to a paper containing a list of names but no heading nor explanatory statement, and were told in answer to any inquiry as to the object of the request that it was an acknowledgement that they had been carefully examined, or that they had had a satisfactory examination; whether the Minister of National Service was aware that these signatures were, as a rule, asked for before the grading had been determined or communicated, and while the recruit was still unclothed; and whether instructions would be given for the practice to be discontinued. Mr. Beck replied that the information was not quite accurate. It was desired to obtain the observations of the men themselves as to whether they had any complaints to make in connexion with the examination. It was thought that this was in the interest of the recruits themselves, and would be a valuable guide to those entrusted with the arrangements and conduct of their medical examination, but as it appeared from the question that the course adopted was open to misconception, he would undertake to see that a procedure was taken which could not give rise to any such misconception.

Sanatorium Treatment in London.—In reply to Mr. Booth, Mr. Haye Fisher, on June 5th, said that the population in the London County Council area in the middle of 1917 was slightly over four millions. The estimated expenditure of the London County Council in the treatment of tuberculosis during the last financial year was £35,000. The actual expenditure for the previous year, 1916-17, was £28,359. In addition, the Metropolitan Asylums Board incurred during that year a gross expenditure of £64,831, and a net expenditure of £33,557 on the treatment of tuberculosis. The London County Council did not erect or manage sanatoriums, but during the past year had contracted with the Metropolitan Asylums Board and with other sanatorium authorities for the provision of about 580 beds. The total number of beds provided in the institutions of the Asylums Board for the treatment of tuberculosis is about 780, apart from beds reserved for children under the care of guardians.

Plague-infected Rats.—In reply to an inquiry by Sir Shirley Benn, as to what precautions had been taken to prevent the cargo from ss. *Somali* conveying plague into England, Mr. Haye Fisher said, on June 5th, that no disinfection of the cargo was considered necessary. To prevent the risk of plague-infected rats reaching the shore with the cargo, the ship remained moored in the river and the cargo was discharged bale by bale from the deck into lighters alongside. This proceeding accorded with the recommendation of the International Sanitary Convention (Paris, 1912) and offered the best security available. The disinfection of the vessel after the cargo was unloaded was undertaken with the main object of destroying rats in the ship. The quarters occupied by the plague cases were disinfected as soon as the men had been removed to hospital.

Bombing of Hospitals.—Replying to Mr. Joynson Hicks, Mr. Macpherson said that a recent report from the Commander-in-Chief showed that during the period from May 15th to June 1st, hospitals had been bombed on seven occasions. The casualties occurring in hospitals were not given separately from those caused in the district by the same raid. The total casualties in these seven raids were as follows:

	Killed.	Wounded.	Total.
Officers	11	18	29
Other ranks	218	534	752
Sisters	5	11	16
Queen Mary's Army Auxiliary Corps ..	8	7	15
Civilians	6	23	29
	248	593	841

In reply to a further question by Mr. Joynson-Hicks, on June 12th, Mr. Bonar Law said that he was unable to make any further statement, as the report upon the subject had not yet been received.

Payments to Auxiliary Hospitals.—In reply to Colonel Sir Frederick Hall, on June 5th, Mr. Forster said that the rates paid to hospitals for military patients were not in all cases the same, but the standard maximum rate for the great majority of auxiliary hospitals was now 3s. 3d. per occupied bed and 6d. per unoccupied bed a day. In January, 1915, the corresponding rate was 3s. per occupied bed, and there was no grant for unoccupied beds. In response to a suggestion by Sir Frederick Hall that the increase was inadequate in view of the advance in cost of food, Mr. Forster said that the new grant of 6d. per unoccupied bed represented a substantial sum.

Dental Surgeons Commissioned in the Army.—Mr. Macpherson informed Mr. Pennefather on June 10th that the number of qualified dental surgeons holding commissions in the army was 640. Of these 92 had received their commissions since March 1st, including 26 from the ranks. Inquiry would be made how many remained in the ranks.

THE late Brigade Surgeon John Law, Indian army, left £49,953 gross. After several legacies, he bequeathed the residue of his estate to King Edward's Hospital Fund for London.

A FRANCO-PERUVIAN hospital was lately formally opened in Paris in the presence of the Peruvian Committee, of which the chairman is General Benavides, a former President of the Republic of Peru, and representatives of the Association of French Ladies. The hospital, which contains eighty beds, will be maintained at the expense of the Peruvian colony.

OWING to shortage of turpentine in Germany, benzol has largely been used as a substitute in paint, varnish, etc. The result has been widespread benzol poisoning among painters working in ill-ventilated interiors of ships. The Minister for Commerce and Industries has issued stringent regulations to combat this danger. No workman may paint in an unventilated limited space for more than half an hour at a time, and he must spend at least half an hour in the open before resuming work. Several other precautions are to be taken.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON PROBATIONER M. D. CADMAN, R.N.V.R.

Surgeon Probationer M. D. Cadman, R.N.V.R., was reported as killed, in the casualty list published on June 10th.

ARMY.

Killed in Action.

CAPTAIN F. A. J. R. BROOKE, R.A.M.C.

Captain Frederick Arthur John Robertson Brooke, R.A.M.C., attached Wiltshire Regiment, was killed in action on May 27th. He was educated at the London Hospital, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1894. He took a temporary commission as lieutenant in the R.A.M.C. on July 10th, 1916, and was promoted to captain after a year's service. He had recently been serving as physician at Tidworth Military Hospital. His son, Lieutenant Cecil Rupert Brooke, Gordon Highlanders, was killed in France on April 24th, 1917.

CAPTAIN T. MOHAN, R.A.M.C.

Captain T. Mohan, R.A.M.C., was reported as killed in action, in the casualty list published on June 5th.

Died of Wounds.

CAPTAIN E. E. MEEK, C.A.M.C.

Captain E. E. Meek, Canadian Army Medical Corps, was reported as having died of wounds, in the casualty list published on June 10th.

CAPTAIN F. G. THATCHER, M.C., R.A.M.C.

Captain Francis Geoffrey Thatcher, M.C., R.A.M.C., died on June 1st of wounds received on May 30th, aged 27. He was born on September 24th, 1890, the youngest son of Mr. C. H. Thatcher, F.R.C.S.Ed., of Edinburgh, and was educated at the university in that city, where he graduated M.B. and Ch.B. in 1913. He entered the R.A.M.C. as lieutenant on July 31st, 1914, and was promoted to captain on March 30th, 1915. His Military Cross was gazetted on June 3rd, two days after his death.

Died on Service.

LIEUTENANT T. FORREST, R.A.M.C.

Lieutenant Thomas Forrest, R.A.M.C., attached Indian Army, was reported as having died on service, in the casualty list published on June 10th. He was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1917, and, after acting as house-surgeon of the Western Infirmary, Glasgow, took a temporary commission as lieutenant in the R.A.M.C.

Wounded.

Lieut.-Colonel H. Moore, M.C., R.A.M.C. (temporary).

Major F. C. Chandler, R.A.M.C. (T.F.).

Major T. M. Furber, Australian A.M.C.

Major C. H. Westley, Australian A.M.C.

Captain D. C. G. Ballingall, M.C., R.A.M.C.

Captain T. H. Campbell M.C., R.A.M.C. (temporary).

Captain G. E. Charters, R.A.M.C. (temporary).

Captain J. C. Dunn, D.S.O., M.C., R.A.M.C. (temporary).

Captain F. Humphreys, R.A.M.C. (temporary).

Captain P. W. Kent, R.A.M.C. (T.F.).

Captain J. G. Lee, R.A.M.C. (temporary).

Captain E. H. Rainey, R.A.M.C. (temporary).

Captain G. P. Searle, Canadian A.M.C.

Lieutenant G. Blair, R.A.M.C. (temporary).

Missing.

Colonel A. Milne-Thomson, C.M.G., R.A.M.C. (T.F.).

Prisoners of War.

Captain A. J. Chillingworth, R.A.M.C. (temporary).

Captain A. B. Cluckie, R.A.M.C. (temporary).

Captain F. T. H. Davies, R.A.M.C. (temporary).

Captain C. E. P. Husband, R.A.M.C. (temporary).

Captain R. A. Leembruggen, R.A.M.C. (temporary).

Captain G. R. Lipp, M.C., R.A.M.C. (temporary).

Captain D. Macnair, R.A.M.C. (T.F.).

Captain C. O'Malley, M.C., R.A.M.C. (temporary).

Lieutenant W. H. Rowden, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Kennefick, John G. Hammertou, Captain Essex Regiment, son of the late Dr. Kennefick, of Clonmel, Tipperary, killed April 20th. He attained his rank on December 11th, 1914. His maternal grandfather was General Hammerton, C.B., who commanded the 44th Foot at Waterloo.

Spooner, Bernard, Royal Field Artillery, second son of Dr. Spooner of Clapton, died of wounds on May 23rd.

Stuart, Peter Dudley, Captain Royal Air Force, younger son of the late Dr. Peter Stewart, of Blundellsands, accidentally killed flying in Lincolnshire, on June 1st, aged 24. He got his first commission on September 3rd, 1914. He had gained the Croix de Guerre.

MEDICAL STUDENT.

Fraser, George D., Second Lieutenant Rifle Brigade, who recently died of wounds, aged 19, was the eldest son of Mr. Robert Fraser, registrar and inspector of poor, Inverary. He was a medical student at the University of Edinburgh, received his commission from the O.T.C. in September, 1917, and went to the front in the following month.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

BIRTHDAY HONOURS.

ORDER OF THE BRITISH EMPIRE.

THE following are among the promotions in and appointments to the Order of the British Empire, for services rendered in connexion with the war:

To be K.B.E.

Dr. Edward Marriott Cooke, Chairman of the Board of Control.

 Khan Sahib Sayad Nazir Hussain, I.S.M.D., Civil Surgeon, Mianwali, Punjab.
 Captain Robert Kirkpatrick, C.A.M.C.
 Dr. James MacLachlan, Honorary Secretary Sutherland Branch, Scottish Branch, British Red Cross Society.
 Miss Florence Marie Morris, M.B., Commandant and Medical Officer in Charge, Paignton Auxiliary Hospital, Devonshire.
 Dr. Albert Alfred Osborne, Commandant and Medical Officer in Charge, Ilfracombe Auxiliary Hospital, Devonshire.
 Dr. Leslie Powne, Commandant and Medical Officer in Charge, Crediton Auxiliary Hospital, Devonshire.
 Lieutenant John Ritchie, Second in Command of Army Medical Store, Woolwich.
 Miss Mary Thompson Ritchings, M.B., Ch.B., Medical Officer in Charge, Y.M.C.A., Auxiliary Hospital, Swansea.
 Captain James Maxwell Ross, F.R.C.S.Ed., County Director, Dumfries, Scottish Branch, British Red Cross Society.
 Mr. Albert Charles Butler-Smythe, F.R.C.S.Ed., member of a Recruiting Medical Board.
 Mrs. Emma Christine Williams, M.B., B.S., Medical Officer at a Shell Filling Factory.

Mr. Frederic G. Hallett, secretary, Committee of Reference, is appointed an officer of the Order, and Lieut.-Colonel Orland K. Gibson, Deputy Director of Dental Services, Canadian Forces, Mr. Edmund T. Gaun, civil assistant to the Director-General A.M.S. and Miss A. L. Lawrence, assistant secretary, Central Medical War Committee, are appointed members.

The following members of the medical profession are among the recipients of the medal of the Order of the British Empire for services in connexion with the war in which great courage or self-

sacrifice has been displayed: Dr. Ernest James Berkley and Dr. Athol Raymond Moore, for rescue work on the occasion of a Zeppelin raid, and Dr. Edward Wright (Divisional Surgeon Metropolitan Police) for attending to the injured on the occasion of an air raid.

MENTIONED IN DISPATCHES.

THE following are among the names of those brought to notice in a dispatch, dated March 25th, by Lieut.-General G. F. Milne, K.C.B., D.S.O., Commander-in-Chief, British Salonica Force, for gallant and distinguished services rendered from September 21st, 1917, to February 28th, 1918:

Staff.

Colonel G. T. Rawnsley, C.B., C.M.G., A.M.E.
 Lieut.-Colonel P. H. Henderson, D.S.O., R.A.M.C.

Royal Army Medical Corps.

Lieut.-Colonel M. M. Lowlesley.
 Temporary Lieut.-Colonel C. M. Wenyon, C.M.G.
 Major (acting Lieut.-Colonel) F. J. Garland.
 Major R. K. White.
 Temporary Major H. W. Wiltshire.
 Captain and Brevet Major (acting Lieut.-Colonel) B. Johnson.
 Captain (acting Major) A. L. Urquhart.
 Captains E. Davies and A. M. McCutcheon.
 Temporary Captains: D. I. Aederson, G. V. Bakewell, D. M. Borland, R. C. Brown, P. C. Davie, T. E. George, L. G. McCune, J. H. McNicol, M. C. F. H. Merrell (Special List), E. C. Whita, A. Wilkin.
 Temporary Lieutenant E. Gardner.

Royal Army Medical Corps (Special Reserve).

Captains: T. Y. Barkley, M. C. Cooper, G. G. Drummond, J. A. Musgrave, H. B. Sherlock, M.C., H. W. Torrance.

Royal Army Medical Corps (Territorial Force).

Lieut.-Colonel J. R. Whait.
 Major and Brevet Lieut.-Colonel F. E. A. Webb.
 Captain (temporary Lieut.-Colonel) H. G. G. Mackenzie.
 Captain (temporary Major) A. W. Falconer, D.S.O.
 Captains: C. E. C. Ferrey, L. A. Harwood, W. H. Manson, B. E. Potter, P. S. Price, G. White, H. W. Weir.
 Quartermaster and honorary Captain G. W. Harris.

Indian Medical Service.

Temporary Lieutenant H. S. Rajan.

NOTES.

Fleet Surgeon William Wallace Keir, R.N., is among the officers mentioned in dispatches (*London Gazette*, June 7th).

L'ENTENTE MÉDICALE.

For a considerable time past, owing to the fact that French and British troops have been fighting in the same areas, French wounded have reached British casualty clearing stations and British wounded have reached the corresponding French units (*hôpitaux d'évacuation*). *Le Journal* has called attention to the fact that recently this has happened on a much larger scale, owing, no doubt, to the unification of the chief command and the consequent more intimate mingling of French and British troops. The intention is that a French soldier treated at a British clearing station or a British soldier treated at a French evacuation hospital should be sent on from there to the hospital on the lines of communication provided by his own country, but this has not always been possible, and many French wounded have, we believe, reached British hospitals on the lines of communication and even at the base. Our contemporary states that the converse recently happened on a somewhat large scale. After a recent offensive the large evacuation hospital under the control of the military Government of Paris received a large number of British wounded. The first arrivals were admitted to the hospitals at St. Cloud, Astoria, and the Bois de Boulogne, and the overflow were sent on to the French Red Cross hospitals, where our allies were thoughtful enough to send nurses who could speak English well. As soon as they were fit to be moved on the men were sent by hospital trains to ports of evacuation. On June 8th General Phillips, commandant of the British zone in Paris, formally thanked M. Louis Mourier, Under Secretary of State, for the great care and skill expended on the British wounded. M. Mourier immediately transmitted the thanks of the British general to the medical inspector of the district, General Février, and to his fellow workers, medical and nursing.

Scotland.

VENEREAL CLINIC IN EDINBURGH.

A BRANCH of the National Council for Combating Venereal Disease was formed at a public meeting called by the Lord Provost on June 5th. The scheme for a venereal clinic in Edinburgh, which Dr. Leslie Mackenzie said would shortly receive the sanction of the Local Government Board, covers not only Edinburgh but the three Lothians. Provision is made for a special department at the Royal Infirmary, to be open at convenient hours, and also for indoor treatment. Provision is also made for expert advice for medical men and institutions, and it is intended to establish pathological laboratories for diagnosis. The meeting was attended by Sir Francis Champneys and Mrs. Gotto (representing the

National Council). The latter spoke of the necessity of protecting the ignorant from the devices of quacks, the enactment against whom was not being enforced. The motion for the appointment of the local committee was made by Councillor Young, convener of Edinburgh Public Health Committee, seconded by Dr. McKenzie Johnston, President of the Royal College of Surgeons, and supported by Sir Robert Philip and Professor Russell, President of the Royal College of Physicians.

TREATMENT OF DISABLED SOLDIERS.

At the monthly meeting of the Joint Institutional Committee of Scotland, held in Edinburgh on June 8th, the chairman, Sir Arthur Boscawen, M.P., Parliamentary Secretary to the Ministry of Pensions, announced that Major Grant had presented his house and grounds at Kilgaston, Perthshire, to be used as an institution for permanently disabled men. It will be available for patients from all parts of Scotland, and will be managed by a committee appointed by the Central Area Committee. The orthopaedic annexe at Tynecastle, Edinburgh, will, it is expected, be ready in July. A scheme for providing after-sanatorium treatment for discharged men suffering from tuberculosis at the Polton Farm Colony was approved by the meeting, which also received a report from the South-Western Committee on the necessity for providing a hospital to give in-patient treatment to discharged men from the West of Scotland. A scheme was also considered for an annexe at the Moffat institution for pensioners for discharged men suffering from rheumatism.

WORKING OF INSURANCE.

Speaking at the first of a series of lectures arranged by the Scottish Insurance Commission, to be given in different centres, Sir James Leishman, chairman of the commission, said that in spite of the war the financial experience of last year had been satisfactory. Payments into the Scottish fund amounted in round numbers to 12 millions; payment out for sickness, disablement, and maternity benefit was very nearly 4 millions, and 3 millions had been paid out for medical benefit, sanatorium benefit, and the working of insurance committees and societies. Nearly 5 millions was invested. There were substantial balances to the credit of almost all the societies in Scotland, and there was no reason for the loose statements that the Insurance Act and the societies were bankrupt.

Ireland.

MEETING OF MEDICAL DELEGATES.

At a largely attended meeting of delegates of the Irish medical profession held in the Royal College of Surgeons, Dublin, on May 29th, 1918, the following resolutions were passed:

Reappointment of Irish Medical Committee.

- (a) That the Irish Medical Committee be reappointed; that it be constituted as arranged at the delegates' meeting July 13th, 1913, and that it be empowered, if it think desirable, to give adequate representation on its body to any medical association or organization for which provision was not made at the aforesaid delegates' meeting.
- (b) That for the purpose of recording the views of the medical profession in Ireland in connexion with Irish medical affairs, and, when necessary, promoting legislation thereupon, the Irish Medical Committee, owing to its representative character and constitution, be regarded the authoritative body with regard to such matters.

Salaries of Poor Law Medical Officers.

- (1) That this meeting of delegates, representing the medical profession in Ireland, is of opinion that the initial salary for dispensary districts should be £200 per annum, increasing to a maximum of £300 per annum after fifteen years' service; that in the case of existing officers these terms should have retrospective application, and that a special scheme of salaries be drawn up by the Irish Medical Committee for medical officers of workhouses.
- (2) That the Irish Medical Committee, acting in conjunction with the local medical committees, take such action that pressure can be brought to bear from the central committee to supplement the demands for increased scales of salaries put forward by counties or union areas; that in the event of boards of guardians refusing to grant adequate salaries, that the medical officers in the areas concerned communicate with the secretaries of the Irish Medical Committee before taking further action.

Medical Benefits under Insurance Act.

That we approve of the extension of medical benefits to Ireland on terms suitable and acceptable to the profession in this country.

Deputation to Local Government Board.
